In formal consultation, FWS must analyze "the best scientific . . . data available" on the status of the species, and determine how the species would be affected by the proposed action. 16 U.S.C. § 1536(a)(2). At the conclusion of consultation, FWS issues a biological opinion ("BiOp") that includes an analysis of the direct and indirect effects of the proposed action and the cumulative effects of, as well as the FWS' determination as to whether the proposed action is likely to jeopardize the continued existence of a listed species or destroy or adversely modify any designated critical habitat. *See* Consultation Handbook at 4-14 to 4-31. Even after the BiOp is issued, ESA regulations require that formal consultation be reinitiated where "new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered. 50 C.F.R. § 402.16.

The Corps determined that NISP "is likely to adversely affect" the threatened Preble's meadow jumping mouse, the endangered whooping crane, the endangered interior least tern, the endangered pallid sturgeon, and the threatened piping plover. FEIS at App'x D. Accordingly, on February 5, 2007, the Corps requested to initiate formal consultation with FWS. *See* 50 C.F.R. § 402.14 (requiring action agency to undertake formal consultation when it finds that listed species may be present in the project area and that the proposed action "may affect" listed species or critical habitat); *see also* FWS, Endangered Species Consultation Handbook ("Consultation Handbook") at 3-13 (1998). Consultation was concluded on October 5, 2007, and FWS issued a BiOp summarizing the direct and indirect effects of the proposed action on the five listed species, the cumulative effects of reasonably certain future state, tribal, local, and private actions, and the FWS' opinion that NISP was not likely to jeopardize the continued existence of any of the listed species.

However, as discussed extensively above, the Corps' water quality analyses are fundamentally flawed, and therefore cannot serve as a basis for an effects determination. *See* 16 U.S.C. § 1536(a)(2) (requiring consultation to be based on "the best scientific . . . data available"). Therefore, the BiOp's conclusion that NISP is not likely to adversely affect listed species is legally inadequate and must be redone using the best—and most accurate—scientific data available.

The Corps has represented that it "will complete Section 7 consultation with the [FWS] before the ROD." FEIS at A-119. Specifically, the Corps has stated that it will prepare a Biological Assessment to determine whether NISP is likely to adversely affect listed species. However, in light of the flaws in the underlying data on which FWS originally based its conclusion, the Corps must reinitiate *formal* consultation with FWS and obtain a new BiOp *before* any action is taken to approve Northern Water's permit application. *See* 50 C.F.R. § 402.16 (requiring the reinitiation of formal consultation where "new information reveals effects of the action that may affect listed species or critical habitat in a manner or to an extent not previously considered").

The 2007 BiOp is woefully inadequate, and the Corps is prohibited from making any irreversible or irretrievable commitment of resources that would foreclose "the formulation or implementation of any reasonable and prudent alternatives" until the reinitiated consultation is concluded and a new BiOp is issued. 50 C.F.R. § 402.09. Should the Corps fail to obtain an adequate biological opinion and incidental take statement, any activities taken by the Corps and/or Northern Water in implementing this Section 404 permit that are likely to result in the incidental take of members of listed species are unlawful. 16 U.S.C. § 1538(a)(1)(B). Accordingly, should Northern Water undertake such activities, or should the Corps authorize such activities, *id.* § 1538(g), either entity may be subject to criminal and civil federal enforcement actions, as well as civil actions by citizens for declaratory and injunctive relief, *see id.* § 1540.

E. The Corps Must Ensure that Northern Water Obtains an Incidental Take Permit Under BGEPA Prior to Issuing Any Permit.

BGEPA prohibits the "take" of bald and golden eagles without a permit. 16 U.S.C. § 668(a). "Take" is statutorily defined to include "molest or disturb." *Id.* § 668c. Regulations promulgated to implement BGEPA elaborate that "disturb" means "to agitate or bother" an eagle "to a degree that causes, or is likely to cause, . . . (1) injury . . . , (2) a decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior, or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior." 50 C.F.R. § 22.3.

The FEIS reports that the construction of Glade Reservoir would permanently affect 8 acres of bald eagle nest buffer. FEIS at 4-385. Additionally, Glade Reservoir would be developed as a recreational site, with public access to a fishery, and opportunities for fishing, boating, hunting, camping, hiking, horseback riding, and biking. FEIS at 4-476 to -477. Northern Water would provide funding for the development of recreational facilities. *Id.* Therefore, it is highly likely that the construction and operation of the reservoir and associated activities will disturb bald eagles. Therefore, the Project cannot lawfully proceed in the absence of a permit issued pursuant to BGEPA by FWS. By the same token, the Corps cannot issue a Section 404 permit authorizing the project without simultaneously insuring that the project will be constructed and operated in such a manner as to comply with BGEPA, including BGEPA's permitting requirement. Indeed, to do otherwise would place the Corps itself in legal jeopardy under the APA, which prohibits federal agency action that is "arbitrary, capricious, an abuse of

discretion, *or otherwise not in accordance with law*." 5 U.S.C. § 706(2)(A) (emphasis added).[22] Therefore, contrary to the Corps' representation in the FEIS, *see* FEIS at 4-385 (asserting that compliance with BGEPA is the responsibility of Northern Water), the Corps must ensure that Northern Water complies with BGEPA *prior* to issuing a permit under Section 404.

CONCLUSION

For the foregoing reasons, the FEIS for NISP is legally deficient. If the Corps nonetheless proceeds to issue a Section 404 permit under the CWA, it will be doing so in clear violation of federal environmental law. In lieu of taking that step, the Conservation Organizations urge the Corps (and Northern Water) to explore less environmentally destructive alternatives and to solicit public comment on those additional alternatives, as well as the other issues raised herein.

Sincerely,

/s/ Elizabeth Lewis
Elizabeth Lewis

/s/ William S. Eubanks II
William S. Eubanks II

[22] NISP cannot proceed in the absence of a BGEPA permit. To issue an incidental take permit under BGEPA, FWS must find that the taking is "*necessary* to protect a legitimate interest in a particular locality," and that the "applicant has avoided and minimized impacts *to the extent practicable*," 50 C.F.R. § 22.26(f) (emphasis added). Thus, BGEPA requires FWS to scrutinize whether there are "practicable" alternative routes that would avoid or minimize eagle impacts. In addition, the issuance of a BGEPA permit is itself a federal action triggering NEPA responsibilities to take a "hard look" at environmentally enhancing alternatives.

Re: Request For Supplemental NEPA Review By The Corps For The Northern Integrated Supply Project In Light Of Significant New Information Bearing On The Proposed Action

On behalf of the nonprofit organization Save The Poudre, I hereby request that the U.S. Army Copy of Engineers ("Corps") conduct supplemental environmental analysis pursuant to the National Environmental Policy Act ("NEPA"), 42 U.S.C. §§ 4321-4370m, by preparing a supplemental environmental impact statement ("SEIS") or, at bare minimum, a supplemental environmental assessment ("EA") to address and evaluate new circumstances and significant information relevant to this project and its environmental impacts. As explained below, **we request a response from the Corps by no later than March 29, 2019** informing Save The Poudre whether the Corps intends to conduct any supplemental NEPA review, and, if not, explaining the reasons why the Corps has declined to take this action.

BACKGROUND

I. STATUTORY AND REGULATORY FRAMEWORK

Congress created NEPA more than four decades ago "[t]o declare a national policy which will encourage productive and enjoyable harmony between man and his environment; to promote efforts which will prevent or eliminate damage to the environment . . . ." 42 U.S.C. § 4321. In light of this mandate, the Supreme Court has reasoned that NEPA is "intended to reduce or eliminate environmental damage and to promote 'the understanding of the ecological systems and natural resources important to' the United States." *Dep't of Transp. v. Pub. Citizen*, 541 U.S. 752, 756 (2004) (quoting 42 U.S.C. § 4321).

In achieving NEPA's substantive goals, Congress created two specific mechanisms through which federal agencies must evaluate the environmental and related impacts of a

particular federal action—an EIS and an EA. *See* 42 U.S.C. § 4332(c). These procedural mechanisms are designed to inject environmental considerations "in the agency decisionmaking process itself," and to "'help public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment.'" *Pub. Citizen*, 541 U.S. at 768-69 (emphasis added) (quoting 40 C.F.R. § 1500.1(c)). Therefore, "NEPA's core focus [is] on improving agency decisionmaking," *Pub. Citizen*, 541 U.S. at 769 n.2, and specifically on ensuring that agencies take a "hard look" at potential environmental impacts and environmentally enhancing alternatives "as part of the agency's process of deciding whether to pursue a particular federal action." *Balt. Gas & Elec. Co. v. Nat. Res. Def. Council*, 462 U.S. 87, 100 (1983). The alternatives analysis "is the heart" of an EIS or EA. 40 C.F.R. § 1502.14. NEPA's implementing regulations require that the agency "present the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice among options by the decisionmaker and the public." *Id.*

An EIS must be prepared by an agency for every "major Federal action significantly affecting the quality of the human environment." 42 U.S.C. § 4332(c). Under the Council on Environmental Quality's ("CEQ") regulations that implement NEPA, "significance" requires consideration of both context and intensity. Where a significant environmental impact is not expected, the agency must still prepare an EA and a Finding of No Significant Impact ("FONSI"). *Id.* §§ 1508.9, 1501.3. Where an EA or EIS has been previously prepared, NEPA's regulations require an agency to supplement its prior NEPA review when "[t]he agency makes substantial changes in the proposed action that are relevant to environmental concerns," or "[t]here are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts." 40 C.F.R. § 1502.9(c).

II. FACTUAL BACKGROUND

The Corps commenced its decisionmaking and NEPA review process for the Northern Integrated Supply Project ("NISP") in August 2004. *See* Corps, *Environmental Impact Statement – Northern Integrated Supply Project*, https://www.nwo.usace.army.mil/Missions/Regulatory-Program/Colorado/EIS-NISP/. The Corps issued its Draft EIS in April 2008, its Supplemental Draft EIS in June 2015, and its Final EIS in July 2018. *Id.* According to the Corps' project website, the agency intends to issue a Record of Decision ("ROD") authorizing this project later this year (i.e., in 2019). *Id.*

It would be a major understatement to say that this project has engendered substantial controversy. Save the Poudre, affected municipalities such as the City of Fort Collins, and many other interested parties have submitted extensive comments criticizing myriad aspects of the Corps' decisionmaking process including the agency's impermissibly narrow purpose and need statement, the artificially constrained analysis of practicable alternatives, the use of inappropriate screening criteria in examining project alternatives, and major project impacts that have not been adequately analyzed. Those comments are all part of the public decisionmaking record.

DISCUSSION

Although the Corps evidently intends to issue its ROD later this year, the Northern Colorado Water Conservancy District ("Northern Water")—i.e., the project proponent—recently made a major change in project operations that alters many of the basic assumptions underlying the NISP project and the ability of Northern Water to fill the proposed Glade Reservoir. On February 28, 2019, Northern Water revealed—*for the first time ever*—that, in order for NISP to be viable, Northern Water may have to purchase at least "25,000 acre-feet of water" from northern Colorado farmers, which Northern Water representatives estimate "would take about a decade and 100 or more farms, depending on their size." Loveland Reporter, *Northern Water Buys First Farm for NISP Water* (Feb. 28, 2019), *available at* http://www.reporterherald.com /news/larimer-county/ci_32483944/northern-water-buys-first-farm-nisp-supply. Indeed, in purchasing its first water from a northern Colorado farm in furtherance of NISP, Northern Water spent $330,000 to purchase a mere 30 acre-feet of water—i.e., $11,000 per acre-foot. Even assuming other farms will sell to Northern Water at no more than this rate (a proposition that is far from certain), purchasing all of the required water would add an additional $275 million in total project costs. *See id.* On the same day that local newspapers revealed this approach, Northern Water separately unveiled its new regime—called the WaterSecure program—and launched a website providing information about it. *See* Northern Water, *WaterSecure*, *available at* https://www.northernwater.org/sf/nisp/watersecure. For several reasons, these purchases would represent a wholesale change to the approach Northern Water will take to acquire the water for NISP, and is a fundamentally different and highly significant modification to the project that bears directly on the proposed action, its impacts, and its alternatives.

First, Northern Water's new approach of purchasing some or all of the required 25,000 acre-feet of water from northern Colorado farms—i.e., more than 60% of the 40,000 annual acre-feet of water that Northern Water alleges is a necessary project component of NISP—has *never* been analyzed as part of the Corps' Draft EIS, Supplemental Draft EIS, or Final EIS. To the contrary, the Final EIS makes clear that under Northern Water's preferred alternative—as well all other action alternatives—"$0" would be spent on "water rights acquisition." Final EIS at 2-103. In contrast, the Corps estimated that under the *no-action* alternative, Northern Water would have to spend $700 million on water rights acquisition by buying water rights from farms at approximately $15,500 per acre-foot. *See* Final EIS at 2-102. Accordingly, because Northern Water's new approach fundamentally transforms the preferred action and its underlying assumptions and operational mechanics, at minimum the Corps must prepare supplemental NEPA review disclosing to the public this new approach and soliciting public input on this substantial change.[1]

[1] The Final EIS states that Northern Water already owns the water rights necessary to implement the preferred alternative. *See* Final EIS at 2-77 ("With the exception of Upper Galeton Reservoir as a point of storage for the SPWCP water right, *Northern Water owns the water rights with the necessary points of diversion and storage for Alternative 2M*." (emphasis added)). Thus, the fact that Northern Water actually does *not* own some of these water rights—to the tune of 25,000 of annual acre-feet of water (more than half the water Northern Water claims to need from this project)—is a colossal change in the preferred alternative that alters the entire landscape of this project is a significant way.

Second, supplemental NEPA review is necessary because Northern Water's new approach completely alters the baseline against which practicable alternatives are measured, especially in light of the significantly increased project costs. Even if Northern Water is able to buy 25,000 acre-feet at approximately $11,000 per acre-foot—which is not certain given the fair market price for such water rights, *see* Final EIS at 2-102—this would add at least $275 million to overall project costs, which means that certain alternatives previously dismissed due to higher costs might now be "practicable" when compared to the much higher costs of the preferred alternative in light of Northern Water's new farm purchasing scheme. Given the new cost baseline for the project, the Corps must re-examine all practicable alternatives as judged against the new projected costs of Northern Water's preferred alternative.[2]

Third, the Corps and Northern Water previously rejected alternatives that included as a component alternative agricultural transfer methods (including agricultural leasing), and did so by implementing faulty screening criteria for proven technology—i.e., rejecting the leasing of agricultural water on the purported grounds that such methods are technologically unproven. *See* Final EIS at A-115 (EPA comments advocating the consideration of alternative agricultural transfer methods). Now that Northern Water has dramatically changed course and *is* purchasing and/or leasing water from northern Colorado farms, the Corps must revisit the concept of alternative agricultural transfers and analyze other alternatives involving this concept that is, in fact, feasible as demonstrated by Northern Water's selection of this new approach to acquire more than half of the water needed for this project to be viable.

Fourth, Northern Water's significant change in operations for the preferred alternative necessarily modifies many of the key factors under NEPA related to this project, such as the purpose and need and whether the preferred alternative can even achieve the purported need for this project. In particular, since there is much uncertainty as to whether and when Northern Water would be able to achieve its goal of purchasing 25,000 acre-feet of water from northern Colorado farms, it is highly speculative as to whether the preferred alternative can provide 40,000 acre-feet of water (which is a requirement to satisfy the project's stated need).[3] The Corps

[2] The costs associated with NISP have grown exponentially since the beginning of this project. In 2008, the Corps estimated that the project would cost $350 million. By the 2018 Final EIS, the Corps estimated that the project would cost $1.1 billion—i.e., three times what the Corps estimated only ten years earlier. With Northern Water's new approach, the estimated costs will increase at least another $275 million and likely much more than that as farms sell their water rights at higher per-unit rates.

[3] Northern Water has indicated that it intends to resell the purchased land, conditioned to allow the exchange to operate in perpetuity, and may claim that such transactions will allow them to make these purchases at zero cost. *See* Loveland Reporter, *supra* ("Eventually, the district plans to sell the farms to private owners, he said, with the stipulation that the water would stay with the property."). Until such a time as Northern Water can provide signed contracts for resale of all of the purchased land, this approach remains speculative at best. Even if Northern Water was able to eventually resell all of the properties at favorable prices—which is far from certain—the project would incur substantial carrying costs associated with land ownership in the interim.

must analyze the likelihood that Northern Water will be able to acquire the rights to 25,000 acre-feet of water, the estimated costs of doing so, the anticipated time frame before such acquisition is completed, and what happens in the event that Northern Water is not able to acquire 25,000 acre-feet of water through this new approach.[4]

Fifth, the modeling conducted to date by the Corps and/or Northern Water is no longer accurate since the modeling assumptions previously used in assessing mass-balance water quality and return flow obligations fail to include any analysis of this new approach and how those projections change if Northern Water is (or is not) able to purchase 25,000 acre-feet of water from farms.

Sixth, there will be highly significant environmental impacts under Northern Water's new approach, in which the project proponent will separate Poudre river water from the land and replace it with South Platte water (then reselling and/or leasing the land to an irrigated agricultural user). Because of the multi-river issues inherent in this approach, there are myriad adverse effects to water quality, wildlife, and other aspects of the ecosystem that the Corps has not yet examined. The need for a "hard look" at these new impacts counsels in favor of supplemental NEPA review.[5]

Seventh, now that Northern Water's preferred alternative and the no-action alternative *both* involve as a key component the purchase of many acre-feet of water from farms, there is not an alternative that is genuinely distinct from the action alternatives. Because the Corps must include an analysis of a true no-action alternative—which must be conceptually distinct in terms of its components from the action alternatives—supplemental NEPA review is necessary to ensure that the agency explores a genuine no-action alternative as a proper baseline for assessing the action alternatives against that no-action standard.

None of these costs have been disclosed in any of the NEPA documents to date, nor compared to alternatives in determining the practicability of other approaches.

[4] Not only will Northern Water's new approach dramatically increase overall project costs and the amount of time before the project is viable due to water rights acquisition, but there will be additional costs and time expended addressing water rights issues associated with this new approach in water court. These costs and delays must also be examined as part of a supplemental NEPA analysis.

[5] Under this new approach, every purchase/exchange allows Northern Water to displace clean Poudre River water with more contaminated and more polluted water from the South Platte River. The mixing of water from these two sources will very likely adversely impact water quality for all ditch customers, including landowners who have *not* sold or leased their water rights to Northern Water. The Corps must analysis these water quality impacts, which require landowners who refuse to sell to Northern Water to nevertheless accept more polluted and lesser-quality water from the South Platte that otherwise would flow from the much cleaner Poudre River, and would require this outcome presumably without any compensation for those landowners from Northern Water or the Corps.

Eighth, in conjunction with this new approach, Northern Water expects to exchange 25,000 acre-feet of water between several ditch companies and the NISP participants. However, there is nothing in the Final EIS or elsewhere quantifying the costs of any contracts or other agreements with these ditch companies, nor any evaluation of what happens if the ditch companies are unwilling to partner with Northern Water on this project. This, too, must be addressed through supplemental NEPA analysis.

Ninth, supplemental NEPA review is necessary because Northern Water's new approach to the preferred alternative changes the assessment of impacts to the irrigated agriculture-related economy of northern Colorado. Whereas the Final EIS stated that the no-action alternative "would likely result in a moderate to major effect on irrigated agricultural economy in the study" due to widescale purchase of water rights under the no action alternative, Final EIS at 4-541, the Corps stated that "[u]nlike the No Action Alternative, Alternative 2M would not relay on transfers of agricultural water rights as a source of supply"; "[c]onsequently, there would not be effects on the irrigated agriculture-related economy due to water transfers." *Id.* at 4-545. Clearly, the Corps' earlier assumption that the preferred alternative would not involve transfers of agricultural water rights is no longer accurate, nor is the conclusion accurate that the local agricultural economy will not be impacted by implementation of the preferred alternative. This aspect of the Final EIS needs to be revised to account for current information on the preferred alternative and to accurately identify economic and other effects that will reasonably flow from Northern Water's new approach.

Given the many areas of the Final EIS that are now outdated, inaccurate, or flawed, it is imperative that the Corps update its analysis of project impacts, alternatives, and purpose and need. This critically important information requires supplemental NEPA review addressing these concerns both because Northern Water has made "substantial changes in the proposed action that are relevant to environmental concerns," and the new approach constitutes "significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts," 40 C.F.R. § 1502.9(c)(1). Thus, because agencies "shall prepare supplements" to final EISs where either criterion is satisfied, *id.*, the Corps must conduct supplemental NEPA review and issue an SEIS (or at least a supplemental EA) addressing this vitally important issue that is central to the Corps' purpose and need analysis, evaluation of reasonable alternatives that could satisfy the need for this project, and the ultimate decision as to whether the Corps should authorize this project under Section 404 of the Clean Water Act. In conducting supplemental NEPA review, Save The Poudre strongly urges the Corps to subject that document to public comment and input, in light of the controversial nature of this project and the immense public interest in this project shown to date by Colorado residents. In our view, absent a supplemental NEPA analysis incorporating the new elements of the preferred alternative and public comment on that evaluation, the Corps' action would not satisfy NEPA's "hard look" standard and would, instead, be sweeping vital aspects of this project and its effects under the rug,

CONCLUSION

For the reasons explained above, Save The Poudre believes that the Corps must conduct supplemental NEPA review as directed by the CEQ's NEPA regulations to analyze various aspects of Northern Water's new WaterSecure program and how it impacts this project, its purpose and need, its impacts, and feasible alternatives. Please let me know by **no later than March 29, 2019** if the Corps intends to prepare a Supplemental EIS or EA in response to this letter and the significant new information identified herein. If the Corps decides not to conduct any further NEPA review despite the new information set forth in this letter, please provide a written response by March 29 explaining the reasons why the Corps has declined this request. I look forward to hearing from the Corps about this matter. Please let me know if you would like to schedule a conference call to discuss this matter in person.

Respectfully submitted,

William S. Eubanks II

Subject: NISP SDEIS Review

The Environmental and Science Advisory Board has reviewed the Supplemental Draft Environmental Impact Statement (SDEIS) for the Northern Integrated Supply Project (NISP) and offers the following comments.

General Observations:

The environmental analysis for the SDEIS has significantly advanced from the Draft Environmental Impact Statement (DEIS). Notable examples include the updated hydrologic modeling using a Common Technical Platform (CTP) for NISP and the Halligan/Seaman projects, and the hydraulic modeling of sediment transport and aquatic habitat at the six Poudre River study sites.

The SDEIS updates the Participants' current water conservation measures. It is important to acknowledge that conservation measures have resulted in decreases in per capita water use. While conservation measures have helped to manage existing developed water supplies, the Participants have demonstrated that they have a need for additional water in the future.

Even with the advances noted above, gaps remain in the information necessary to make the final selection of the least damaging practical alternative and appropriate mitigation measures. Examples of information not available for public review at this SDEIS stage include preparation of the Supplemental Biological Assessment, completion of the Phase II water quality and stream temperature modeling, and completion of the mitigation plan.

We appreciate the Army Corps of Engineers (Corps) taking another look at hazardous materials contamination at the Atlas Missile Site. We believe that the impact assessment is sound and the proposed project changes are appropriate to address potential impacts.

The No Action alternative developed for the SDEIS does not accurately describe the current trajectory of events because it requires development of a new water project (Cactus Hill Reservoir) that would require a separate permitting process similar to NISP.

Based on the limited available data, the Preferred Alternative (Alternative 2) has an important advantage over Alternatives 3 and 4 in that it requires the smallest total withdrawal of water. However, a number of specific issues discussed below prevent an effective assessment of the impacts from any of the alternatives compared to current or future conditions.

Serious Concerns:

Impacts on Surface Water

As was criticized in the DEIS, *monthly* flow data are not applicable for evaluating environmental impacts of the alternatives on streamflow and create a false impression that environmental impacts have been properly characterized. Instead, *minimum* and *maximum daily* flow data provide the most appropriate information to assess environmental effects. However, daily flow data presented in the SDEIS are mostly *median* flows, which are also uninformative of environmental effects. New figures need to be created illustrating the *minimum* and *maximum* daily flows of each of the alternatives.

Figures of the more useful daily flow data are poorly presented in the SDEIS and technical reports such that it is difficult to adequately assess environmental impacts. For example, figures of the time series of the maximum, mean, median, and minimum daily flows (e.g., Water Resources Technical Report Figure 6.15) do not graph the y-axis on a logarithmic scale. Another example is the figures of daily flow duration curves (e.g., SDEIS Figure 4-30) that do not graph the y-axis on a logarithmic scale. Distinguishing the effects of the alternatives on daily flow durations at high and low exceedance probabilities is problematic because of this incorrect scaling. Additionally, figures such as SDEIS Figure 4-2 need to compare the minimum and maximum, not the median, daily flows. Full interpretation of environmental impacts would be facilitated if these figures displayed the effects of the alternatives as a percentage change from the current or future conditions hydrology.

No standard scientific performance metrics are given in the SDEIS or technical reports as evidence of how well the CTP hydrology model performed. Confidence in any of the flow-related resource effects analyses is limited because it is unknown how well the CTP simulated the observed streamflow.

Impacts to Fish Habitat

Habitat suitability curves were developed from data on habitat use by fish during low flows, but the depths and velocities measured during this time do not represent the depths and velocities available during high flows. The curves are scientifically and statistically unsound because they were projected from low flow data into times of high flows that are beyond the range of observed depths and velocities. Interpretations of habitat use during spring runoff are unfounded because the lack of observations results in predictions with extreme uncertainty. Moreover, the interpretation that habitat use by fish will increase during spring runoff because the alternatives will reduce high flows demonstrates a misunderstanding of fish ecology in rivers that are primarily influenced by snowmelt. High flows are important, not for habitat use by fish during spring runoff, but because they maintain the channel and resulting habitat that is available to fish during low flows throughout the remainder of the year. Predicting habitat use by fish in the main channel during spring runoff is not meaningful, except for adults of species that spawn during this time.

Physical habitat data presented in the SDEIS and technical reports provide flawed information for determining environmental impacts of the alternatives on fish (e.g., Figure 3-2, Aquatic Biological Resource Effects Technical Report). The data that are presented for weighted usable area (WUA) in median, 20th and 80th percentile *WUA years* are artificial and unrealistic representations of habitat availability in any given year. They are specific to each species and life stage of fish, meaning that they are not comparable to one another and are unacceptable for discriminating the different effects of the alternatives. Figures should present data for WUA in median, 20th and 80th percentile *streamflow years* because it allows the differentiation of the alternatives' effects on fish by showing how WUA will be affected in any given dry, average, or wet streamflow year.

Impacts to Water Quality

Water quality impacts to the Poudre River below the project diversion are a serious issue that has not been addressed in adequate detail in the analyses and proposed mitigation actions. The information in the SDEIS is insufficient to demonstrate that exceedances of water quality standards will not occur. We acknowledge that additional important Phase II water quality modeling is still ongoing and strongly urge the Corps to issue the completed modeling study as an addendum to the SDEIS so that it can be subject to public review prior to publication of the Final Environmental Impact Statement (FEIS).

Mitigation Measures:

The descriptions of mitigation actions are still not specific enough, despite numerous comments from stakeholders (e.g., EPA Region 8 and City of Fort Collins) that reviewed the DEIS in 2008. Likewise, the mitigation activities generally do not explain how or why they will be effective at alleviating adverse environmental impacts.

Hydrology will be impacted by the project, creating a cascade of impacts that include changes in stream morphology and sediment transport, alteration of aquatic and riparian habitat, degradation of water quality, and increased risk of flooding in the lower reaches of the Poudre River. The mitigation measures under consideration are not sufficient to address these serious impacts. Acceptable mitigation actions also need to include the provision for episodic high spring flows in the Poudre River to promote natural geomorphic processes and rejuvenation of instream and floodplain habitat. Such a measure would ideally be provided in partnership with other projects (e.g., Halligan/Seaman) to increase its effectiveness.

A credible rationale should be provided regarding the effectiveness of two proposed actions in mitigating adverse environmental impacts of the Preferred Alternative: 1) the proposed low flow augmentation to maintain 10 cubic feet per second (cfs) in winter, and 2) the proposed channel and habitat improvements to rehabilitate two 1.2-mile river reaches. An explanation should be provided in the SDEIS or technical reports that clarifies why releasing this minimum flow or rehabilitating this distance of river at these two sites would be beneficial to aquatic or riparian biological resources. It is suggested that the low flow augmentation will increase habitat availability for fish, but this alone is not a well-reasoned argument for its effectiveness.

As shown in the SDEIS and technical reports (i.e., Stream Temperature and Dissolved Oxygen Analysis, Table 4), temperature excursions are already happening in March and July through September in Segment 10, and in July and August in Segment 11. These temperature excursions are likely to increase with the Preferred Alternative, particularly in July and August. The proposed low flow augmentation would not mitigate this impact because water releases would occur in September and in November through April, but not in July and August, when excursions will have the most significant environmental impact on fish. Furthermore, the proposed Glade Reservoir enlargement also would not mitigate temperature excursions in July and might exacerbate them. However, this proposed mitigation (i.e., enlargement) is illogical because it would attempt to mitigate the adverse impact of Glade Reservoir during summer low flows by intensifying its adverse impact on spring high flows.

Principal Recommendation:

We recommend that the additional technical information and mitigation measures planned for the FEIS be prepared and presented as part of an addendum to the SDEIS. The addendum will allow the public and the Corps access to adequately detailed information that is sufficient to select the least damaging practical alternative and evaluate necessary mitigation measures.

Comments on Draft Environmental Impact Statement for Northern Integrated Supply Project

Dated: September 10, 2008

City Manager's Office
300 LaPorte Ave
PO Box 580
Fort Collins, CO 80522
970.221.6505

fcgov.com

September 10, 2008

Mr. Chandler J. Peter
U.S. Army Corps of Engineers
Denver Regulatory Office
9307 South Wadsworth Blvd.
Littleton, CO 80128-6901

Dear Mr. Peter:

Please find accompanying this letter detailed comments and associated reference material from the City of Fort Collins regarding the Draft Environmental Impact Statement for the Northern Integrated Supply Project. Please make this submission a part of the administrative record in this matter. We respectfully submit these comments for your consideration and look forward to the Army Corps' response.

A public review version of these comments (without technical references) will be posted on the City's web site at: http://fcgov.com/nispreview/

On September 2, 2008, the Fort Collins City Council unanimously adopted Resolution 2008-082 (see attached), directing that these comments be submitted on behalf of the City. By the same Resolution, City Council also endorsed a City request that the Corps issue a Supplemental Draft Environmental Impact Statement. This request is being made so that there would be further analysis by the Corps intended to respond to the comments of the City and others, and also further opportunity for review and comment by the public after the Supplemental has been completed. In addition, the Council expressed its opposition to the project as it is described in the Draft Environmental Impact Statement.

If you have any questions, please feel free to contact me, or you may also contact Kevin Gertig with our Utility at (970) 221-6637, or John Stokes with our Natural Resources Department at (970) 221-6263.

Thank you.

Sincerely,

Darin Atteberry
City Manager

RESOLUTION 2008-082
OF THE CITY OF FORT COLLINS
DIRECTING THE CITY MANAGER TO SUBMIT TO
THE U.S. ARMY CORPS OF ENGINEERS COMMENTS ON
THE DRAFT ENVIRONMENTAL IMPACT STATEMENT ("DEIS")
FOR THE NORTHERN INTEGRATED SUPPLY PROJECT ("NISP")
AND EXPRESSING THE CITY COUNCIL'S OPPOSITION
TO NISP AS DESCRIBED IN THE DEIS

WHEREAS, the Northern Colorado Water Conservancy District (the "District") is seeking approval of a large water storage and supply project known as the Northern Integrated Supply Project ("NISP"); and

WHEREAS, in order to move forward with the necessary permitting for NISP, the District is required by the National Environmental Policy Act ("NEPA") to complete an environmental impact review process, conducted in this case by the U.S. Army Corps of Engineers (the "Corps") as the permitting agency under the federal Clean Water Act; and

WHEREAS, as part of the review process, the Corps on April 30, 2008, issued a draft Environmental Impact Statement ("DEIS") describing the "proposed action" and three alternative projects, and the environmental impacts associated with each, and providing for submission of public comment up to September 13, 2008; and

WHEREAS, the proposed action involves the construction of a new reservoir to the northwest of Fort Collins near the mouth of the Cache la Poudre River ("Glade Reservoir") and related projects; and

WHEREAS, at the direction of City Council, City staff has undertaken a thorough and detailed technical analysis of the DEIS primarily as it pertains to the proposed action and its direct impacts in Fort Collins and to the City; and

WHEREAS, based on the efforts of City staff, working with the assistance of outside technical experts, the City has concluded that the DEIS is substantially deficient in its analysis of potential impacts to the City; and

WHEREAS, the City's review has identified major adverse impacts that the proposed action would have upon that portion of the Cache la Poudre River that flows through Fort Collins and is a focal feature of the City's Downtown River Corridor Project, and upon other short-term and long-term City interests, plans and projects; and

WHEREAS, based on its thorough and detailed analysis, the City also believes that the proposed action as described in the DEIS will have profound and detrimental impacts upon associated aquatic and terrestrial plant and animal populations; the use and value of recreational facilities, parks, natural areas and other public assets on or near the river in Fort Collins; the quality

of City drinking water sources and supply, City wastewater treatment operations and restrictions, stormwater and floodplain mapping and requirements in the Poudre River Basin; quality of life and economic development in the City; and other matters of concern to the City; and

WHEREAS, such impacts to the City's economic plans, its quality of life, and in particular to the City's drinking water sources and supply and wastewater treatment operations could cause one-time damages in excess of $200 million and ongoing costs of millions of dollars annually; and

WHEREAS, in the course of its review of the DEIS, the City has identified data gaps, insufficient analyses, and technical inconsistencies and significant errors in the DEIS that call into question and undermine important conclusions in the DEIS; and

WHEREAS, to the extent reasonably possible in view of these data gaps, limitations, and errors, the limited time for review of the DEIS, and the lack of information and description provided in some portions of the DEIS pertaining to the proposed action, City staff has outlined major comment themes (the "Comment Themes") as the basis for a formal comment document to be prepared and submitted to the Corps by its September 13, 2008, deadline, as more specifically described on Exhibit "A", attached hereto and incorporated herein by this reference; and

WHEREAS, in order to maximize the amount of staff time available to further develop, refine, and finalize the comments to be submitted to the Corps, the City Manager has requested and recommended that the Council approve the Comment Themes as the general basis for the comments to be submitted to the Corps, recognizing that staff's ongoing work will produce a better refined, more comprehensive and technically detailed explanation of the Comment Themes, and the primary and other issues within each Comment Theme, and additional related matters identified as concerns regarding the DEIS; and

WHEREAS, the Council has reviewed the preliminary review information at the Council's December 11, 2007, and June 10, 2008, work sessions, and at this September 2, 2008 regular meeting, and has considered the Comment Themes and supporting information provided by staff, and supports the approach that the City Manager has recommended; and

WHEREAS, it is clear from the Comment Themes, the DEIS, and staff's analysis that the DEIS is substantially deficient and that a Supplemental Draft Environmental Impact Statement must be prepared by the Corps in order to meet the requirements of NEPA and the federal Clean Water Act; and

WHEREAS, in view of the significance of the impacts that NISP would have upon the City and the Fort Collins community, it is in the City's best interest to comment upon the DEIS and the proposed action and to carefully monitor the response to the City's comments and other comments submitted.

NOW THEREFORE, BE IT RESOLVED BY THE COUNCIL OF THE CITY OF FORT COLLINS as follows:

Section 1. That the City Council opposes NISP as it is described and proposed in the DEIS and also opposes any variant of NISP that does not address the City's fundamental concerns about the quality of its water supply and the effects on the Cache la Poudre River through the City, which are critical to the City's quality of life, health, economic development and environment.

Section 2. That the City Manager is hereby authorized and directed to further develop, refine and finalize formal comments for submission to the Corps that are consistent with and that build upon the Comment Themes and this Resolution, and to submit those comments to the Corps in response to the NISP DEIS in accordance with the deadline for such submission.

Passed and adopted at a regular meeting of the Council of the City of Fort Collins this 2nd day of September A.D. 2008.

Mayor

ATTEST:

City Clerk

EXHIBIT "A"
SUMMARY OF COMMENT THEMES
NISP DRAFT EIS

1. WATER MANAGEMENT ISSUES - Source Water Quality

Issue: Deliveries to Horsetooth Reservoir from the Glade-to-Horsetooth pipeline for NISP have the potential to degrade water quality at the Fort Collins Water Treatment Facility intake at Soldier Canyon Dam.

2. WATER MANAGEMENT ISSUES - Wastewater Treatment

Issue: ***Reduced flows in the Cache la Poudre River and degradation of water quality in the River due to NISP may force the City to design, operate, and maintain, "advanced wastewater treatment systems" at great expense.***

3. WATER MANAGEMENT ISSUES - Trichloroethylene (TCE) Groundwater Contamination

Issue: TCE contaminates groundwater near the Glade pumping site and NISP may cause TCE to contaminate public drinking water supply and/or the Cache la Poudre River.

4. ENVIRONMENTAL ISSUES - Riparian Vegetation and Wetlands

Issue: Reductions in annual Spring flows in the Cache la Poudre River of from 25% to 71% are expected to have a significant detrimental impact on the riparian vegetation in the River corridor through Fort Collins.

5. ENVIRONMENTAL ISSUES - Aquatic Habitat Quality and Aquatic Life

Issue: The hydrologic, geomorphic, and water quality changes from NISP are expected to have a significant detrimental impact on fish and aquatic insects in Fort Collins.

6. ENVIRONMENTAL ISSUES - Terrestrial Wildlife and Bird Species within the Poudre River Corridor

Issue: The DEIS and Wildlife Technical Report fail to adequately identify and analyze the potentially significant impacts the proposed action could have on terrestrial wildlife and bird species within the Cache la Poudre River's riparian corridor.

7. ENVIRONMENTAL ISSUES - Loss of River Channel Capacity through Sedimentation

Issue: Increased sedimentation of the Cache la Poudre River through Fort Collins is expected to reduce river channel flood capacity.

8. RECREATION ISSUES

Issue: Reduced flows in the Cache la Poudre River, and the effects on the River corridor from reduced flows, are expected to have a significant detrimental impact on recreation along the River, including boating, tubing, fishing, walking, biking, running, hiking, and nature and wildlife viewing.

9. AESTHETIC AND SOCIOECONOMIC ISSUES – Aesthetics

Issue: Reduced flows in the Cache la Poudre River, and the effects on the River corridor from reduced flows, are expected to have a significant, detrimental impact on the aesthetics of the River corridor.

10. AESTHETIC AND SOCIOECONOMIC ISSUES - Socioeconomics

Issue: The DEIS does not address socioeconomic impacts NISP would have on Fort Collins (other than recreation), which may be significant and are expected to be detrimental.

11. CUMULATIVE IMPACTS

Issue: The DEIS section on "Reasonable Foreseeable Actions" does not identify or consider several important Fort Collins projects, such as the Discovery Science Museum, the Mason Transportation Corridor, and other planned improvements that have a relationship to the River.

12. MITIGATION

Issue: The DEIS does not develop sufficient information regarding impacts to predict impacts in a meaningful way, hindering consideration of avoidance, minimization and mitigation of impacts. The DEIS offers mitigation ideas but insufficient information to allow evaluation of those ideas. The mitigation approaches that are suggested in the DEIS have not been sufficiently analyzed to know whether they will effectively address the concerns they are intended to address. Moreover, the DEIS fails to offer any mitigation measures at all for several of the City's concerns.

13. CLIMATE CHANGE AND AIR QUALITY IMPACTS

Issue: The analysis of climate change and air quality impacts from NISP in the DEIS is inadequate, and the DEIS does not sufficiently characterize or address these impacts.

14. ERRORS AND OMISSIONS

Issue: The DEIS contains other technical, procedural and logical errors and omissions that impact the validity and sufficiency of the conclusions.

Comments on Draft Environmental Impact Statement
for
Northern Integrated Supply Project

Dated: September 10, 2008

Table of Contents

City of Fort Collins NISP DEIS Comments
September 10, 2008

Part I - EXECUTIVE SUMMARY

EXECUTIVE SUMMARY

The City of Fort Collins (City) respectfully files these comments on the Northern Integrated Supply Project (NISP) Draft Environmental Impact Statement (DEIS) issued by the United States Army Corps of Engineers (Corps) on April 29, 2008. Based on a thorough, scientific review of the DEIS by expert City staff and consultants (see biographies in Appendix A to these Comments), the City has concluded that the DEIS fails to sufficiently analyze the impacts of NISP and does not provide for the avoidance of the extensive impacts NISP would have on the City and its residents. It would be illegal to approve a permit for NISP based on the current record and project definition.

Accordingly, a Supplemental Draft Environmental Impact Statement (SDEIS) is necessary to meet the Corps' legal obligations under Section 404 of the Clean Water Act (Section 404) and the National Environmental Policy Act (NEPA). Because NISP would cause extensive impacts to the City's environment, quality of life, economy, property and budget, and NISP does not provide adequate safeguards, the City opposes NISP as it is described in the DEIS.

1. NISP Would Cause Significant Impacts to the Water Quality of Horsetooth Reservoir and to the Cache la Poudre River in Fort Collins

The City would be directly affected by NISP. NISP would build, among other things, the new 170,000 acre-foot Glade Reservoir just north of Ted's Place on U.S. Highway 287, a pipeline between the Glade Reservoir and Horsetooth Reservoir (a critical source of the City's drinking water) and a relocated U.S. 287[1]. NISP would take as much as 71 % of the water out of the Cache la Poudre River upstream of the City and place it into the Glade Reservoir. As described in the DEIS, a portion of the Glade water would be conveyed to Horsetooth Reservoir, where it would degrade the quality of the water that enters the City's drinking water treatment facility.

The City depends on the quality of its water supplies. The City provides customers some of the best water in the country, which is critical to both residents and businesses. Many of the City's largest employers – high tech companies like Hewlett-Packard and Kodak and breweries like Anheuser Busch, New Belgium and Odell – depend on this high-quality water for their processes. Degradation of one of the City's two primary sources of water, Horsetooth Reservoir, could require the City to spend in excess of $90 million in capital costs and almost $3 million annually to maintain the quality of the water delivered to customers. NISP would cause reductions in the Poudre River's flows through Fort Collins as predicted in the DEIS, which may require the City to spend up to $125 million on upgrades to wastewater treatment facilities to protect the River.

[1] For the purpose of these comments, the Cache la Poudre River is also referred to as "the Poudre River" and "the River."

The health of the Cache la Poudre River is vital to the City and its residents. The City developed along the Cache la Poudre River and is now focusing some of its key economic redevelopment along it. The City's more than 1,400 acres of Natural Areas and several Parks along the River are integral to the City's quality of life. Businesses value the City's quality of life due to the role it plays in attracting and retaining high-quality employees. The River is a focus for recreational activity such as boating, cycling, walking, tubing, fishing and bird-watching. Degradation of the River threatens the quality of life of City residents.

2. The Corps Has Not Fulfilled its Obligation to Analyze and Protect the River and City's Drinking Water Supply

The Northern Colorado Water Conservancy District (the District or NCWCD) is required to secure a permit from the Corps under Section 404 of the Clean Water Act before developing NISP. Under Section 404 and its implementing regulations, the Corps may not issue permits to projects that will cause significant degradation of the aquatic ecosystem. 40 C.F.R. § 230.11. To meet its permitting duty, the Corps must assess adverse impacts by analyzing the consequences of proposed discharges on the "physical, chemical, and biological components of the aquatic environment." 40 C.F.R. § 230.11. It must also consider potential adverse impacts to municipal and private water supplies, and possible loss of quality, including effects on color, taste, odor, chemical content and suspended particulate concentration. 40 C.F.R. § 230.50. Clean Water Act regulations further require the Corps to evaluate effects on recreational fisheries, water-related recreation, aesthetics, parks and wilderness areas, and similar preserves. 40 C.F.R. §§ 230.51 – .54. The Corps must take a hard look at the environmental consequences of the proposed action, including the downstream impacts to the Cache la Poudre River in Fort Collins.

Despite the clear legal duty to analyze the impacts of NISP on the River and the City's water quality, the DEIS fails to do so. The DEIS is riddled with omissions, inaccuracies, errors, inconsistencies and improper approaches that make it inadequate as a matter of law. The DEIS fails to adequately and accurately acknowledge the serious impacts of NISP. For example, the DEIS provides no meaningful plan for the operation of NISP, making it impossible to understand exactly how NISP would affect the River or Horsetooth Reservoir. And, because the DEIS underestimates the impacts associated with NISP, it also fails to provide adequate measures to avoid and minimize these impacts.

3. The DEIS Does Not Adequately Analyze the Impacts of NISP on Fort Collins

The following paragraphs summarize some of NISP's impacts and the DEIS deficiencies of greatest concern to the City, which are treated in detail in later sections of these Comments. These are not technicalities, but fundamental concerns that affect real people's lives. At stake is the ability of parents to bring their children to the River without algae blooms, for fishermen to still use their favorite close-in spot for catching large brown trout, for families to wade or tube in the River, for the City and Northern Colorado to continue to succeed in attracting the best high-technology employers, and for homeowners and businesses to avoid the ravages of floods.

3a. City Drinking Water Sources

The DEIS underestimates the effects that NISP will have on the quality of water that the City uses for drinking. Glade Reservoir would be filled with runoff season high flows in the Cache la Poudre River, water that has much higher levels (almost twice as high on average) of Total Organic Carbon (TOC) as the Colorado-Big Thompson (C-BT) water stored in Horsetooth Reservoir. TOC is of central importance to water supplies, because it reacts with the chlorine necessary to treat water to form cancer-causing agents called disinfection byproducts. The levels of these disinfection byproducts allowed in public drinking water are limited by the federal Environmental Protection Agency (EPA) to protect human health. The City already expends considerable effort and resources to remove TOC as part of the treatment process.

Under the NISP proposal, much of the high TOC water from the Glade Reservoir would be piped to Horsetooth Reservoir and released close to the City's water treatment facility intake. It would increase TOC levels for the raw water the City treats, degrading the drinking water supplies of the City. In order to meet federal drinking water standards, the City may have to further upgrade its drinking water treatment systems, which could cost in excess of $90 million in capital costs and almost $3 million per year for operations.

The DEIS underestimates this threat to the City's drinking water. For example, the DEIS relies on analysis that underestimates the TOC levels of the water that will fill Glade Reservoir and be piped into Horsetooth Reservoir. The best available information indicates that Glade water would have long-term average TOC levels of at least 5.5 mg/L, (milligrams per liter) almost twice the 2.9 mg/L level of Horsetooth. The DEIS then relies on the unrealistic assumption that the high-TOC water from Glade would be completely mixed with the rest of water in Horsetooth Reservoir and diluted before being used by the City, even though the Glade water would be delivered on the north end of Horsetooth right next to the City's intake.

Because high TOC levels can produce potentially cancer-causing contamination of the City's drinking water and force huge costs on the City, the City manages its water supply so that high levels of TOC in its water supply will be avoided. However, the DEIS fails to provide any meaningful analysis of these impacts or any guarantees they would be avoided, minimized and mitigated. Instead, only vague and unreliable assertions are made that NISP's proponents might examine some mitigation in the future. These assertions do not meet the requirements of the Clean Water Act and NEPA.

3b. Water Quality Impacts to the Cache la Poudre River

NISP will have serious effects on the water quality in the Cache la Poudre River that are not adequately addressed in the DEIS. The water quality of much of the River is already listed as "impaired" by EPA due to fecal contamination and potentially toxic levels of other pollutants. Reducing the flow of the River by 25% to 71% will reduce dilution of treated wastewater treatment and other releases, making the water quality in the River much worse. It will also increase the temperature of the River (which is harmful to fish) and has a detrimental affect on

other water quality parameters, such as pH and unionized ammonia. These impacts to the River may cause algae blooms and reduced dissolved oxygen levels in the River (also harmful to fish), and may make portions of the River a "no body contact" and "no swimming" zone. Lack of sufficient dilution water will degrade the environment, human health, recreational uses and aesthetics of the River. These are fundamental blows to the aquatic ecosystem that, under the Clean Water Act, require denial of the proposed permit or a fundamental restructuring of the proposed project.

The loss of river flows could also be extremely expensive to the City's taxpayers and utility rate-payers. The degradation of water quality in the River due to the loss of river flows may require the City to undertake more advanced wastewater treatment methods at its wastewater facilities. Current professional engineering estimates for such upgrades range from $75 million to $125 million to build facilities and significant additional annual operations costs.

3c. Trichloroethylene (TCE) Contamination

The DEIS fails to adequately address very serious questions about the effect of NISP on toxic contamination from a former Atlas missile site located right at the Glade Reservoir dam site. The former missile base has leaked significant quantities of the cancer-causing solvent trichloroethylene (also referred to as trichloroethene or TCE) into the groundwater at the site. Unless property characterized and addressed, this chemical may eventually reach the Cache la Poudre River. The proposed Glade Reservoir would: (1) raise groundwater levels in the vicinity of the Reservoir, including the plume of trichloroethylene; and (2) lower the groundwater levels near the River as the river flow is reduced or diverted. The net effect would be to increase the likelihood and rate of trichloroethylene migration to the River. This is a significant potential impact to the aquatic ecosystem that could result from the construction of Glade Reservoir. It could result in significant human and wildlife exposure to this hazardous chemical for which the EPA has set a preferred exposure level of zero.

Unfortunately, the DEIS does not seriously address this concern. It unreasonably relies on many untested assumptions and minimal testing to reach sweeping conclusions. It also identifies only minimal mitigation for this impact and defers most attention to this issue until after the project is approved. This is inappropriate under the Clean Water Act and NEPA. Decisionmakers need to consider the potential impacts of putting a reservoir hydrologically above a plume of the cancer-causing trichloroethene *before any decision on NISP is made*. In addition, a more reliable and comprehensive plan will be needed to avoid, minimize and mitigate impacts associated with this toxic plume.

3d. Threats to Fish Habitat and Increased Flooding Risks from Sedimentation

NISP's 25% to 71% reduction in Poudre River flows could also threaten the very structure of the River and its use by people, fish and other creatures. The largest reductions in flow would occur

during the peak of the snowmelt runoff every year. It is these peak "flushing" flows that keep the River healthy. Without the flushing and overbank flows, the River may become choked with sediment that cannot be flushed on a regular basis. Sedimentation destroys spawning habitat for fish and disrupts the insects on which fish feed. It narrows the river channel and leads to growth of more vegetation along sand bars and in the channel, dramatically changing the River's form. This impairs boating, other recreation and the aesthetics of the River.

Just as importantly, the additional sediment and plant growth would tend to reduce the ability of the River to handle flooding when it occurs. Flood control has been a significant concern since the settlement of Fort Collins. In modern times, the City has experienced a number of major (and sometimes fatal) flood events (including 1983, 1997 and 1999). In response, and in anticipation of future flood events, the City has spent millions of dollars on flood management. With the potential for higher floods due to sedimentation and vegetation encroachment, the City's efforts may become inadequate or obsolete and the City could be forced to undertake even more spending to address Poudre
River flood risks.

Despite the fact that the issue of sedimentation was raised during scoping phase of the NISP process, the DEIS dismisses it with little analysis, inconsistent findings, erroneous assumptions and other errors. The DEIS also fails to identify meaningful control measures that would address this very serious public safety and environmental problem that is a core concern under the Clean Water Act.

3e. Impacts to Vegetation and Wetlands Along the River

The DEIS states that the proposed action will cause no loss of riparian/wetland vegetation. This conclusion is unsupported by real data or case studies and inconsistent with the relevant scientific literature.

While the loss of the flushing and overbank flows is expected to lead to an increase in vegetation in the channel of the River, it is likely to cause losses to native vegetation on the River banks associated wetlands, and riverine habitat. The high flows that would be diverted from the River for NISP are critical to maintaining the water table that supports adjoining wetlands and the beautiful and mature cottonwood gallery forest along the River. The reduction in flows could lead to a loss of many important native species and lead to increased invasion by pest species such as Russian Olive or tamarisk.

Despite the fact that the DEIS requirement was triggered by the need for a Section 404 wetlands permit, the DEIS fails to identify jurisdictional wetlands along the riparian corridor through Fort Collins and to evaluate the environmental consequences of the proposed action on those wetlands. This failure to identify jurisdictional wetlands in Fort Collins does not comply with the Clean Water Act and impacts to wetlands are clearly within the range of impacts that must be evaluated.

In addition, the loss of native vegetation is likely to have a profoundly negative effect on the aesthetics of the River and recreation associated with those aesthetics . Moreover, the vegetation and wetlands along the River provide critical habitat for birds and other wildlife that rely extensively on riparian habitat in Colorado's arid climate. The DEIS does a poor job of assessing these impacts and an even poorer job of ensuring that this significant degradation of the environment will not occur.

3f. Impacts to Fish and Wildlife

The sedimentation of spawning grounds, increases in stream temperature, loss of river flows, increased pollution and effects on insects and other sources of food will have a major impact on fish in the River. The DEIS attempts to minimize this problem by using simplistic models that the EPA has already stated are insufficient and by suggesting that that fish would "adapt" to the loss of habitat and degraded water quality. However, loss of certain fish and fish populations in some sections of the River is not adaptation; it is a serious adverse effect on biological resources and recreational opportunities.

The DEIS also largely ignores the effects of NISP on birds and other terrestrial wildlife. This is a critical omission, because riparian zones like the Cache la Poudre River support 82 percent of all of the breeding birds in Colorado and attract 10-14 times the number of migrating birds as upland areas. This includes raptors, migrant songbirds and waterfowl that are treasured by residents and visitors to the City's Natural Areas and Parks. Indeed, the Natural Areas along the River are an oasis of bird life, with 223 identified species. Similarly, the River corridor is the home or migration route for deer, elk, bear, otter, mink and many other animals. It is unreasonable to conclude that losses of major vegetation like the cottonwoods, fish, and insects would not have a significant effect on the birds and other wildlife that rely on the River.

3g. Air Quality and Climate

Surprisingly, the DEIS does not evaluate the effects of changing climate and streamflows on the project and its impacts. The scientific data is clear that the climate in the Poudre River watershed has been changing, affecting streamflows. However, even though the DEIS acknowledges this change, it bases all of its planning on a 50-year data set that ends in the year 2000, ignoring the much drier period of the last eight years. A drier and more variable climate will make the impacts of the project on the River and its water quality more serious. It will also affect the ability of the project to deliver the firm yield of water promised in the DEIS. It is unreasonable to proceed without some understanding of these impacts, especially when other water providers in the area are examining the effects of climate scenarios on water supplies and revising yield projections.

In addition, the DEIS fails to address the importance of the EPA's redesignation of the area in November 2007 as a nonattainment area for ozone. This designation requires much more

extensive analyses of the impact of the project on air quality that are completely absent from the DEIS.

3h. Recreation and Quality of Life

NISP could detract from, or impair recreational uses of, the Cache la Poudre River in Fort Collins for residents and visitors. Reductions in peak River flows would limit the season for kayaking, canoeing and tubing and may make those activities impossible at times if "no human contact" restrictions are necessary due to NISP's detrimental effects on water quality.

NISP would have a similar effect on the pending proposal to establish a whitewater course in the City. As in communities throughout Colorado – such as Golden, Salida, and Denver, to name just three examples -- such a course could be a major attraction and a boon to business development. However, NISP's proposed reductions in river flows make it nearly impossible to justify developing such a beneficial facility.

Similarly, hikers, cyclists, runners and others will likely be deterred by by drastically reduced flows, loss of trees such as cottonwood, and other damages identified above. Fishermen will lose areas of the River that now support fish, and the number of quality fish is likely to drop substantially in the areas where they remain. Birdwatchers will be affected by losses of bird species along the riparian corridor.

These impacts could be a serious blow to the quality of life of many City residents, who value the River as one of the great assets of the City. A recent survey conducted by Dr. John Loomis of Colorado State University found that 75% of City residents use the River for recreation every year. Of the surveyed residents, over 80% of the households believed that a 50% reduction in the River's flow (consistent with the 25% to 71% flow reductions from NISP) would be a bad change. The survey and economic analysis found that the recreational value of the River has a net present value of $283 to $424 million. This figure does not take into account the critical role that the River has in fostering cultural and economic development in the City.

Yet, because the DEIS fails to identify or acknowledge the potential for the serious harms to the River, it unreasonably fails to identify significant impacts that NISP could have on recreation and other quality of life indicators.

3i. Socioeconomic Impacts to Fort Collins and Its Residents

The DEIS gives short shrift to the socioeconomic impacts that NISP could have on Fort Collins. The Socioeconomic Resources Technical Report asserts that "all of the components of NISP action alternatives are located outside of community boundaries." On that basis, it concludes that: "No community cohesion, quality of life or access impacts are associated with any of the action alternatives." In addition to being inaccurate and lacking any basis, the DEIS ignores the role of a healthy River as a key element of the City's Downtown development planning. Several of the City's foundational planning documents are predicated on a healthy Poudre River

ecosystem, with connections and access between the Downtown and the Downtown River Corridor and the North College Corridor. The DEIS fails to take meaningful look at the City's interest and stake in the River as an amenity, and does not address the impact of reduced flows on these connections generally.

More specifically, the DEIS takes the mistaken position that the City's Discovery Science Museum, funded and planned for construction on the River, and the Mason Street Corridor Improvements, preliminarily approved for funding and in environmental review now, are "not reasonably foreseeable," and therefore fails to assess them in the cumulative effects report. In view of the investments the City has made in preparing to move forward with these two projects, among others, these are key omissions from the DEIS's analysis.

The DEIS similarly fails to look at the effects of NISP on other reasonably foreseeable projects that are critically important to attracting and retaining businesses and their employees, such as the Poudre River Enhancement Project, the Colorado State University Clean Energy Cluster and Engines and Energy Conversion Laboratory, the Bohemian Foundation's Amphitheater/Music Venue, and Downtown River District Infrastructure Project.

These are fundamental flaws in the economic impacts discussion in the DEIS, and they must be corrected in order for the DEIS to fulfill the requirements of NEPA.

4. A Supplemental DEIS and Revised 404(b)(1) Analysis Are Necessary to Address the DEIS's Shortcomings. Along with Improving the Data and Analysis of Impacts, the SDEIS and Revised 404(b)(1) Analysis Must Contain Definite and Specific Measures Designed to Avoid, Minimize and Mitigate NISP's Significant Degradation of the Aquatic Environment

Due to the DEIS's manifold inaccuracies, omissions, errors, methodological problems and unsubstantiated conclusions discussed in these comments, the DEIS does not adequately assess the environmental impacts of NISP. To cite just a few examples:

- The DEIS excludes the City's Drake water reclamation facility from its analyses, from which 10 million gallons of treated effluent is being discharged every day, and which is permitted for a discharge of up to 23 million gallons.

- The DEIS bases all of its planning on a data set that ends in the year 2000, ignoring the much drier period of the last eight years.

- The DEIS claims that water temperatures will decrease with reduced flows; in other places it claims that temperatures will increase.

- The DEIS claims that water quality data for certain parameters downstream of the Mulberry facility was not available. However, the City has over ten years of detailed water quality data at the location in question.

- The DEIS states that a U.S. Geological Service (USGS) gage station and water quality monitoring site on the Poudre River does not exist (and thus was not available for analysis) when in fact this data is readily available via USGS websites.

The additional analysis that the City has completed, as described in the City's Comments, reveals that NISP would cause much more serious impacts than is acknowledged in the DEIS. These impacts require the denial of the permit or a much more robust program of avoidance, minimization and mitigation.

Because the DEIS and Section 404(b)(1) Analysis are so fundamentally inadequate and cannot support the Corps' obligations under either the Clean Water Act or NEPA, the Corps must prepare a Supplemental Draft Environmental Impact Statement and Revised Section 404(b)(1) Analysis. These documents must not only address and correct the errors and data gaps discussed in these Comments, but also must include much more rigorous commitments and analysis of proposed measures to avoid, minimize and mitigate the impacts of NISP.

Part II - PROCEDURAL AND LEGAL FRAMEWORK FOR CITY COMMENTS

6. **Because of the DEIS's Failure To Provide Sufficient Analysis of the Impacts of the Proposed Permit and Address Their Avoidance, Minimization and Mitigation, A Supplemental Environmental Impact Statement Is Necessary To Comply With NEPA and the Clean Water Act:** Pg. 34

7. **The Corps May Not Segment or Defer Its Analysis of the Impact of the Glade-Horsetooth Pipeline:** Pg. 37

1. The Corps Has an Obligation to Analyze, Avoid, Minimize and Mitigate Impacts Associated with NISP

1a. Section 404 of the Clean Water Act

The DEIS does not fulfill the requirements and purpose of Section 404 of the Clean Water Act to restore and maintain the integrity of the United States' rivers and other waters. Instead, the DEIS's incomplete and misleading analysis appears designed to facilitate without adequate disclosure a project that would seriously and permanently degrade -- and *reverse restoration* of -- the Cache la Poudre River, as well as the water quality of Horsetooth Reservoir.[2]

The Clean Water Act, 33 U.S.C. §§ 1251, *et seq.*, is a comprehensive statute designed to "restore and maintain the chemical, physical, and biological integrity of the Nation's waters." 33 U.S.C. § 1251(a). To this end, Section 404 of the Clean Water Act prohibits the discharge of any pollutant, which includes dredged or fill material, *id.* § 1362(6), into navigable waters unless authorized by a CWA permit. *Id.* § 1311.

> The statute and legislative history reflects that Congress' intention in enacting the Clean Water Act was focusing on remedying the cumulative industrial and institutional practices that have spoiled much of the Nation's waters, and its concern was assuring high quality in our waters. *See* S. Conf. Rep. No. 1236, 92d Cong., 2d Sess. 99-100 (1972), 1972 U.S. Code Cong. & Admin. News 3668 (conference report explaining that in § 101 of the Clean Water Act, 33 U.S.C. § 1251, congressional intent was to eliminate pollutant discharge, *restore chemical, physical, and biological integrity of the Nation's waters*, set water quality goals, prohibit toxic discharges, and develop waste treatment projects and plans), *reprinted in* 1 *Legislative History of the Federal Water Pollution Control Act Amendments of 1972*, at 282-83 (1973).

James City County v. EPA, 12 F.3d 1330, 1332 (4th Cir. 1993) (emphasis added).

Pursuant to the mandate of Section 404(b) of the Clean Water Act, the EPA and the Army Corps of Engineers (Corps) have jointly issued mandatory guidelines ("the Section 404 Guidelines") that must be followed by the Corps in its permitting decisions under section 404. *See* 40 C.F.R. Part 230.

Under the Section 404 Guidelines the Corps must not issue permits to projects that will have a significant adverse impact on the environment. 40 C.F.R. § 230.11. To fulfill its permitting duty, the Corps is required to assess and calculate adverse impacts by analyzing the short and long term consequences of proposed discharges on the "physical, chemical, and biological components of the aquatic environment." 40 C.F.R. § 230.11. *See Environmental Defense v. Corps of Engineers*, 515 F. Supp.2d 69, 77 (D.D.C. 2007).

[2] Throughout these comments, references to the DEIS implicitly incorporate the Section 404(b)(1) Analysis included in the DEIS, unless otherwise stated.

The Corps may also approve a project only if:

1. It is the least damaging practicable alternative;

2. Its discharges do not cause or contribute to *significant degradation* of the waters of the United States, including the following types of effects;

    a) Human health or welfare, such as municipal water supplies, fish, wildlife and wetlands. [Section 230.10(c)(1)]

    b) Life stages of aquatic life and other wildlife dependent on aquatic ecosystems. [Section 230.10(c)(2)]

    c) Aquatic ecosystem diversity, productivity and stability. [Section 230.10(c)(3)]

    d) Recreation, aesthetic and economic values. [Section 230.10(c)(4)]

3. All appropriate and practicable steps have been taken to **minimize** potential adverse impacts to aquatic ecosystems.

40 C.F.R. § 230.10.

A description of the possible ways to satisfy the above-cited requirements can be found in Subpart H of the Guidelines. *See* Section 230.10(d); and NOTE to Subparts C, D, E and F. In some cases, minimization of the impact may actually require **avoiding** it altogether. *See* Subpart H of the Guidelines; *see also* 33 C.F.R. § 320.4(e) ("Action on permit applications should, insofar as possible, be consistent with, and avoid significant adverse effects on the values or purposes for which those classifications, controls, or policies were established"); and Memorandum of Agreement Between the Environmental Protection Agency and the Department of the Army Concerning the Determination of Mitigation under the Clean Water Act 404(b)(1) Guidelines (Feb. 7, 1990). Any unavoidable impacts have to be **mitigated**.

The DEIS and 404(b)(1) Analysis fail to demonstrate that the Corps has fulfilled the duty to avoid, minimize and mitigate project impacts; accordingly, the documents are not adequate to support issuance of a 404 permit. Rather than make the point repeatedly in these comments that avoidance, minimization and mitigation have not been implemented in the plans for NISP, the City raises it here, with the qualification that it applies throughout. 40 C.F.R. § 230.10, quoted above, imposes this duty. It applies broadly to short-term and long-term effects of the discharge itself and -- importantly -- to secondary effects of the discharge. *Id.* at § 230.11.

Subparts C through F of the Guidelines describe the scope of the impacts subject to the duty to avoid, minimize and mitigate. The Guidelines require the Corps, in the DEIS and 404(b)(1) Analysis, to implement measures that avoid, minimize and mitigate numerous impacts, including "changes in normal water fluctuations [that] … can change *adjacent, upstream, and downstream areas*" (§ 230.24(b)) and activities that affect riffle/pool ratios and "reduce the aeration and

filtration capabilities at the discharge site *and downstream*, … retard repopulation of … *downstream waters* through creation of unsuitable habitat" (§ 230.45) (emphasis added). *See Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1192 (10th Cir. 2002) (Corps violated section 404 by failing to address impacts to wildlife more than 1,000 feet from the discharge site). The scope of the duty to address indirect impacts is discussed in more detail below. The Guidelines call for the Corps to make "factual determinations" and "findings of compliance or noncompliance" that considers the effects described in Subparts C through F, of which the two examples just cited are illustrative. *See* NOTE to Subparts C through F. This the DEIS and 404(b)(1) Analysis fail to do and, as a result, the Corps has failed in its duty to implement all appropriate and practicable steps to minimize potential adverse impacts of NISP. *See also* NOTE to Subparts C, D, E and F ("possible actions *to minimize adverse impacts* … can be found in Subpart H." (emphasis added).

In addition, no discharge may be permitted if it: (1) causes or contributes to violations of any state water quality standards; or (2) jeopardizes the continued existence of a federally threatened or endangered species or adversely affects critical habitat for such a species. 40 C.F.R. §§ 230.10(b)(1), 230.10(b)(3). As discussed in detail in Section III of these comments, all available evidence shows that the proposed NISP project would trigger or exacerbate violations of state water quality standards on the Cache la Poudre River and Horsetooth Reservoir. If so, the permit cannot be approved by the Corps.

Under the Section 404 Guidelines, the Corps also may not issue a permit for NISP if it determines that doing so would be contrary to the public interest based on a "careful weighing" of the probable impacts of the project. 33 C.F.R. § 320.4(a). As is discussed throughout these comments, the current record is inadequate for the Corps to undertake this analysis, because it fails to account for the economic and noneconomic negative impacts of NISP, while exaggerating its benefits.

1b. Section 401 of the Clean Water Act

The City intends to raise specific concerns about water quality impacts of NISP before the Colorado Department of Public Health and Environment (CDPHE) during its consideration of a request for Section 401 certification under the Clean Water Act. *See* 33 U.S.C. § 1341. The City reserves its right to file additional comments during the Section 401 process, any further Section 404 proceedings and any other proceedings relating to NISP.

The City understands that the applicant Northern Colorado Water Conservancy District (NCWCD or District) submitted a request to CDPHE for a Section 401 certification on June 2, 2008. The CDPHE deemed the application insufficient for not providing the information necessary. Letter from Steven Gunderson, CDPHE, to Carl Brouwer, Project Manager, July 30, 2008. Mr. Gunderson's letter stated that "once the EIS is final and all project plans are final, the Division will take the time necessary to properly review the application, review public comments, and make the final decision on the 401 certification."

Because the City of Fort Collins has serious concerns about the water quality impacts of NISP, it has a direct interest in participating in a full and fair 401 certification process. Under the CDPHE regulations, 5 CCR 1002-82 (Regulation 82), this includes public notice and an opportunity to comment on a draft certification decision. As CDPHE has made clear in Mr. Gunderson's letter, this process can only take place after the District submits all information required to reach a certification decision.

Accordingly, it is important to the protection of the City's and the public's interest that the District make a complete submission at the appropriate time. The one-year period for CDPHE review of the request for certification pursuant to 33 U.S.C. § 1341(a) starts to run as of the time that the District makes the required submission. *City of Fredericksburg v. FERC*, 876 F.2d 1109 (4th Cir. 1989). The Corps regulations require a "valid" application to be submitted in order to trigger the one-year period. 33 C.F.R. § 325.2(b)(ii). For the application to be valid, it must contain the information that the certifying agency (CDPHE) needs to conduct certification review. *Bangor Hydro-Elec. v. Board of Environmental Protection*, 595 A.2d 438 (Me. 1991); *Long Lake v. New York State Department of Energy Conservation*, 164 AD 2d 396 (N.Y.A.D. Dept. 3, 1990); *In Re Washington County Hydro Development Associates*, 28 FERC P 61341, 1984 WL 57796 (F.E.R.C.) If the Corps treats June 2, 2008 (or some other date prior to the District's submittal of a complete application as deemed by CDPHE) as a trigger date, it will be in violation of 33 C.F.R. § 325.2(b)(ii) and the other authorities cited above.

1c. National Environmental Policy Act

The National Environmental Policy Act (NEPA) requires the Corps to prepare an Environmental Impact Statement analyzing the impacts of and alternatives to the proposed permitting action under Section 404. NEPA mandates that the Corps take a hard look at the environmental consequences of the proposed action, including any indirect, secondary and cumulative impacts. NEPA specifically requires a "detailed statement" of the environmental impact of the proposed action. 42 U.S.C. § 4332(2)(C). The primary function of this detailed statement is to ensure "a fully informed and well-considered decision." *Vermont Yankee Nuclear Power Corp. v. Natural Resources Defense Council, Inc*., 435 U.S. 519, 558 (1978).

NEPA, like the Clean Water Act, requires the Corps to avoid, minimize and mitigate impacts. NEPA defines this duty as follows:

"Mitigation" includes:

> (a) Avoiding the impact altogether by not taking a certain action or parts of an action.
>
> (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation.
>
> (c) Rectifying the impact by repairing, rehabilitating, or restoring the affected environment.

(d) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action.

(e) Compensating for the impact by replacing or providing substitute resources or environments.

40 C.F.R. § 1508.20.

1d. Summary

As discussed in detail in Parts III-V of these Comments, the DEIS is woefully deficient in its (1) analysis of impacts from the proposed NISP project pursuant to NEPA and the Clean Water Act and (2) avoidance, minimization and mitigation of these impacts under the Clean Water Act. As a result, the Corps cannot proceed to a final EIS or issue a permit pursuant to Section 404 based on this inadequate DEIS. If the project proponent wishes to proceed with the project, a supplemental DEIS (SDEIS) and considerable additional analysis under Section 404 will be necessary.

"The burden of proof to demonstrate compliance with the § 404(b) permit Guidelines rests with the applicant; *where insufficient information is provided to determine compliance, the Guidelines require that no permit be issued*. 61 Fed. Reg. 30,990, 30,998 (June 18, 1996) (citing 40 C.F.R. § 230.12(a)(3)(iv))." *Utahns for Better Transportation v. USDOT*, 305 F.3d at 1187) (emphasis added). The inadequate state of the DEIS shows that the burden of proof regarding compliance is not and cannot be met for the NISP project on the current record.

2. The Corps Must Evaluate Impacts To City of Fort Collins Drinking Water and the Cache la Poudre River, Including Special Aquatic Sites and Other Specially Protected Resources under the Clean Water Act. The EIS Must Examine Indirect, As Well As Direct, Impacts of the Project

2a. Legal Requirement To Study Indirect Impacts in the DEIS

Both NEPA and the Clean Water Act require the Corps to develop complete and scientifically valid analyses of the impacts of the proposed action, as well as the effectiveness of any proposed steps to avoid, minimize and mitigate these impacts. For NISP, this must include thorough and defensible review of (1) the effects of diverting Glade Reservoir water to Horsetooth Reservoir and (2) the serious ecological damage that would be caused by reducing Cache la Poudre River flows by up to 71 percent. However, the DEIS fails to provide adequate analysis of these critical effects on the aquatic environment.

As noted above, the Corps is required to prohibit discharges which result in "significant degradation to waters of the United States." 40 C.F.R. §230.10(c). To determine whether a proposed discharge will result in significant degradation, the Section 404 Guidelines require the Corps to make detailed factual determinations regarding the effects of the discharge on the aquatic ecosystem. *Id.* at §230.10(c). *See also* §230.11. As part of these factual determinations, the Section 404 Guidelines require the Corps to include all "secondary effects" of the proposed fill. 40 C.F.R. § 230.11(h). Secondary effects are effects that are "associated with a discharge of dredged or fill materials, but do not result from the actual placement of the dredged or fill material." *Id.* at §230.11(h)(1). An example of a secondary effect included in the Section 404 Guidelines is "fluctuating water levels … downstream associated with the operation of a dam," explicitly requiring review of the effects of Glade Reservoir operation on the Cache la Poudre River. *Id.* at §230.11(h)(2).

The Corps must also consider the "cumulative effects" on the aquatic ecosystem, *i.e.*, changes attributable to the collective effect of a number of different actions and discharges (*e.g.*, the wide array of different dam and diversion projects that affect or will affect the Cache la Poudre watershed). *Id.* § 230.11(g). *See also Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1190 (10th Cir. 2002) ("The permitting authority is to collect and solicit information about the cumulative impacts on the wetlands, and this information is to be documented and considered during the decisionmaking process concerning the evaluation of the permit application.").

Courts have applied the Section 404 Guidelines' requirement that a Section 404 permit must be denied when secondary impacts are inadequately analyzed, minimized or mitigated. For example, the Tenth Circuit Court of Appeals upheld the Corps' denial of a permit for a proposed earthen dam because of indirect effects of the dam on whooping crane habitat downstream. *Riverside Irrigation Dist. v. Andrews*, 758 F.2d 508 (10th Cir. 1985). As with NISP, the impacts on the habitat were not a direct result of discharge of fill material; rather, they were the anticipated result of increased use of water that the reservoir would bring about.

> The question in this case is how broadly the Corps is authorized to look under the CWA in determining the environmental impact of the discharge that it is authorizing … In the present case, the depletion of water is an indirect effect of the discharge, in that it results from increased consumptive use of water facilitated by the discharge. … To require [the Corps] to ignore the indirect effects that result from its actions would be to require it to wear blinders that Congress has not chosen to impose … There is no authority for the proposition that, once it is required to consider the environmental impact of the discharge that it is authorizing, the Corps is limited to consideration of the direct effects of the discharge.

Id. at 512-13.

The federal district court for the district of Colorado similarly upheld an EPA veto of the §404 permit issued by the Corps for construction of the Two Forks Dam on the upper South Platte River based on indirect impacts to recreational and fishery conditions rather than to water quality

per se resulting from direct discharge of fill material into the river. *Alameda Water & Sanitation Dist.*, 930 F. Supp. 486, 491 (D. Colo. 1996).

Noting that the Section 404 Guidelines "require an accounting of secondary effects on the aquatic ecosystem in addition to direct effects," another federal district court set aside five Section 404 permits granted by the Corps for mountaintop mining and the consequent burial of streams. *Ohio Valley Environmental Coalition v. United States Army Corps of Engineers*, 479 F. Supp. 2d 607 (S.D. W.Va. 2007) (citing 40 C.F.R. §230.11(h)(1)). The court found that the studies in the Corps documents failed to assess properly the effect of the loss of headwater streams on the downstream aquatic ecosystems, a secondary effect of the discharge of fill material.

As explained in detail below, the DEIS is particularly deficient in addressing key indirect impacts, including but not limited to the effects of reduced flows on riparian wetlands and vegetation and the effects of reduced flows and a changed hydrograph on the proposed new watercraft course in Fort Collins. The case law is very clear on the need to do thorough disclosure and analysis of indirect impacts, and this the DEIS fails to do.

2b. Legal Requirements To Study Impacts on City Natural Areas

Further, the Section 404 Guidelines call for special consideration of the numerous special aquatic sites and other protected resources along the Cache la Poudre River. As detailed in Part IV of these comments, the City owns considerable property along the Poudre that it manages for habitat, recreation, and aesthetics. Its Natural Areas and Parks include significant riparian habitat, wetlands, a pedestrian and bike trial, and park land adjacent to the river. Subparts E and F of the Guidelines list specific potential effects that the Corps must consider in assessing whether a proposal complies with the Guidelines and regulations. 40 C.F.R. Part 230, Subparts E and F. Many of these provisions are applicable to the entire reach of the Cache la Poudre through the City.

Subpart E of the Section 404 Guidelines ("Potential Impacts on Special Aquatic Sites") describes impacts to "be considered in making the factual determinations and findings of compliance or non-compliance in subpart B." "Special Aquatic Sites" are defined in Section 230.3(q-1) of the Section 404 Guidelines as:

> geographic areas, large or small, possessing special ecological characteristics of productivity, habitat, wildlife protection, or other important and easily disrupted ecological values. These areas are generally recognized as significantly influencing or positively contributing to the general overall environmental health or vitality of the entire ecosystem of a region.

Specific examples include, in addition to wetlands, wildlife sanctuaries and refuges, and riffle and pool complexes – all of which are present in or along the Cache la Poudre in the City's Parks and Natural Areas. 40 C.F.R. §§ 230.40-45; 40 C.F.R. §230.54.

Similarly, as detailed in Part III, IV and V of these Comments, the action alternatives described in the DEIS would drastically reduce flows in the Cache la Poudre River (by as much as 71 percent), resulting in major impacts to, among other things, stream morphology, riffle and pool complexes, recreational fisheries, wetlands, refuges, terrestrial and aquatic wildlife, boating recreation, birdwatching, trails, parks and aesthetics. *Id.*

The DEIS gives short shrift to these indirect impacts, providing much less analysis in areas away from the Glade Reservoir dam. This renders the DEIS inadequate for public use and for decisionmakers under NEPA and the Clean Water Act. *See Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1180 (10th Cir. 2002) (FEIS inadequate when it failed to consider indirect effects on migratory birds).

2c. Legal Requirements To Address Impacts To City Water Supplies, Parks and Recreation

Subpart F of the Section 404 Guidelines describes potential effects on "Human Use Characteristics" that are applicable to the Cache la Poudre River in the City. It specifically requires that the Corps consider effects on municipal water supplies, recreational and commercial fisheries, water-related recreation, aesthetics, and parks and "similar preserves." 40 C.F.R. §§ 230.50-54. The subsections require the Corps to consider the possible loss of values in all these types of areas; substantial adverse impacts should be considered to exist when the Corps determines the proposal will result in significant degradation, and what kind of avoidance, minimization or mitigation must be attached to a permit, if one is issued. Among the impacts that must be avoided, minimized or mitigated are:

- impacts to municipal water supplies by rendering them unpalatable or unhealthy (*Id.* §230.50);
- impacts to recreational fisheries by, among other things, interfering with the reproductive success of aquatic species or chemical contamination (*Id.* §230.51);
- impacts to water-related recreation such as hunting, fishing, canoeing, and sight-seeing by changing aesthetics of resource area or by changing water qualities like turbidity, dissolved materials, and quality of habitat (*Id.* §230.52);
- impacts to aesthetics by degrading water quality, creating "distracting disposal sites," inducing inappropriate development, or adversely affecting particular features like trails, vegetation, air quality, mood, and noise levels (*Id.* §230.53);
- impacts to parks (including "areas designated under … local ordinances to be managed for their aesthetic, historical, recreational and/or scientific qualities, thereby reducing or eliminating the uses for which such sites are set aside and managed") (*Id.* § 230.54).

As detailed in Part III of these Comments, the DEIS fails to address the impacts of the proposed action on the municipal drinking water supplies of the City, insofar as the proposed Glade to Horsetooth Pipeline would add water to Horsetooth Reservoir from Glade Reservoir – immediately adjacent to the inlet for the City's drinking water supplies – that would have much

higher Total Organic Carbon levels. This high TOC water would impair the quality of the City's water and cause the need for extensive, expensive improvements to the City's drinking water treatment infrastructure. *See* Section III.1 of these Comments.

3. An Essential Predicate for Avoiding, Minimizing and Mitigating Impacts Is Proper Identification and Analysis of Impacts, which the DEIS Fails To Provide; the Corps Must Provide a Scientifically Rigorous Analysis

As detailed in Sections III-V of these Comments, the DEIS has failed to properly assess the impacts of the proposed permitting action and is riddled with missing analyses, inconsistent positions, incorrect or incomplete data, and methodological errors. Section 404 requires the Corps to make detailed and scientifically defensible findings analyzing the short and long term consequences of discharges on the "physical, chemical, and biological components of the aquatic environment." 40 C.F.R. § 230.11. *See Environmental Defense v. Corps of Engineers*, 515 F.Supp.2d 69, 77 (D.D.C. 2007).

"A § 404(b) permit cannot be issued if the proposed discharge will result in significant degradation of the aquatic ecosystem *or if there is insufficient information to make a reasonable judgment as to whether the discharge will result in significant degradation*. 40 C.F.R. §§ 230.12(a)(3)(ii), (iv)." *Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1191 (10th Cir. 2002) (emphasis added). Failure to adequately consider the impacts associated with the proposed action is arbitrary and capricious under both NEPA and the Clean Water Act. *Id.* at 1192.

"Accurate scientific analysis, expert agency comments, and public scrutiny are essential to implementing NEPA." 40 C.F.R. § 1500.1. "For this reason, agencies are under an affirmative mandate to 'insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements [,] identify any methodologies used and ... make explicit reference by footnote to the scientific and other sources relied upon for conclusions[.]' 40 C.F.R. § 1502.24." *Environmental Defense*, 515 F.Supp.2d at 78.

Failure to meet these requirements for scientific integrity and adequacy in NEPA documents undermines the Corps' ability to meet the requirements of Section 404. "*Unless the effects of the activity are properly identified, the agency has not met its legal obligation and any proposed mitigation measures dependant upon an incomplete environmental impact analysis necessarily fail…" Ohio Valley Envtl. Coalition v. United States Army Corps of Eng'rs*, 479 F.Supp.2d 607, 627 (D.W.Va.2007) (emphasis added). For example, failure to demonstrate that proposed mitigation addresses substantial harm to the aquatic ecosystem nullifies compliance with Section 404. *Id.* at 84.

Courts hold the Corps to these requirements. For example, in *Environmental Defense*, the court found that the Corps violated both Section 404 and NEPA when it failed to provide an adequate methodology and facts to support its conclusions regarding impact and mitigation.

> The agency's failure to incorporate known [fish] access issues into its mitigation calculation and to identify evidence supporting its determination that reduced access will be insignificant amounts to a failure to present a "complete analytic defense of its [habitat] model," *Sierra Club v. Costle*, 657 F.2d 298, 333 (D.C.Cir.1981) (internal quotations omitted) *rev'd on other grounds*,463 U.S. 680, 103 S.Ct. 3274, 77 L.Ed.2d 938 (1983). *This omission violates NEPA (requiring "scientific integrity" in environmental impact statements, 40 C.F.R. 1502.24), and undermines the Corps' conclusion that the project complies with CWA* (mandating "appropriate and practicable steps ... [to] minimize potential adverse impacts ... on the aquatic ecosystem,"40 C.F.R. 230.10(4)).

Id. at 81 (emphasis added). "The agency cannot reliably conclude that the selected project has minimized adverse impacts on aquatic ecosystems to the extent practicable when its habitat mitigation calculations are infected with an underestimate of the floodplain habitat impacted. 40 C.F.R. § 230.10(d). … The finding of full mitigation in spite of this omission was arbitrary and capricious." *Id.* at 83. "The agency's discrepant treatment of project impact and project mitigation in this area was therefore unsupported by the record and 'internally inconsistent,' undermined the conclusion that project impacts are minimized to the extent practicable as required by the CWA, and violated NEPA's regulation mandating the scientific integrity of environmental impact statements. *Id.* at 84 (citing *Air Transp. Assn. v. DOT*, 119 F.3d 38, 43 (D.C.Cir.1997).

Similarly, the United States Court of Appeals for the Tenth Circuit also invalidated the Corps' issuance of a Section 404 permit in *Utahns*, where the Corps failed, among other things, to provide a reasonable justification for its omission of an analysis of the impacts of the project at issue on migratory birds. *Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1180 (10th Cir. 2002).

Where a benefit-cost test is used to evaluate a proposed project, NEPA requires agencies to include that test in its environmental impact statement. 40 C.F.R. § 1502.23. The benefit-cost test is therefore subject to the NEPA regulations regarding accuracy and scientific integrity. 40 C.F.R. § 1502.24. As discussed in detail in Section V of these Comments, the DEIS has included some benefit-cost information in its assessment of the public interest test under Section 404, but the benefit-cost analysis is incomplete, biased towards approval and riddled with error. Had all of the elements of cost been included, including extensive costs for water treatment, wastewater treatment upgrades, and recreational costs, the City believes the DEIS would show that Alternative 2 would fail the benefit-cost review and, therefore, the public interest test under Section 404.

4. The DEIS Fails To Satisfy the Obligation to Avoid, Minimize and Mitigate Impacts

Sections III-V of these Comments detail manifold ways in which the DEIS has failed to avoid, minimize and mitigate NISP impacts. The failure stems from a two root causes. First, as

discussed immediately above, the DEIS often fails to adequately portray impacts associated with NISP. Second, even when it does suggest "environmental commitments," the DEIS offers vague, unsupported and unreliable measures without any meaningful performance standards or criteria. *See* DEIS Chapter 5.

The failure of the DEIS to demonstrate how and why proposed measures would address impacts undermines compliance with Section 404. *E.g., Ohio Valley Envtl. Coalition,* 479 F.Supp.2d at 627; *Environmental Defense*, 515 F.Supp.2d at 84. Here, the DEIS did not even fully consider the minimization and avoidance measures that must be considered under Subpart H of the Section 404 Guidelines.

Under the Section 404 Guidelines, the Corps must specify whether a proposed discharge complies with the Guidelines outright; if not, the Corps *must* either deny the permit or show that the imposition of appropriate conditions "to minimize pollution or adverse effects to the affected aquatic ecosystems" will bring the discharge into compliance with the Guidelines. 40 C.F.R. §230.12(a). However, the DEIS fails (1) to adequately identify the adverse impacts; (2) to impose appropriate conditions; or (3) show how the vague and uncertain commitments would result in compliance with the Section 404 Guidelines.

4a. The DEIS's "Commitments" Regarding Total Organic Carbon Do Not Comply with the Clean Water Act

As an example, the DEIS completely fails to address the very serious effects of the NISP project on the quality of the City's water supply. As discussed in detail in Part III of these comments, the proposed action covered under the proposed permit would include a pipeline from Glade Reservoir to Horsetooth Reservoir. Water demand and supply patterns indicate that it is almost certain that this pipeline would be built and used.

Part III also shows that such a pipeline would place water with high levels of Total Organic Carbon (TOC) in the immediate vicinity of the City's Soldier Canyon intake to its water treatment system. TOCs lead to disinfection by-products that are regulated under federal drinking water standards because of their role as probable carcinogens. The delivery of Glade Pipeline water to Horsetooth creates a very high probability that disinfection by-product levels in City water would increase beyond acceptable levels under federal drinking water standards without massive upgrades of the City's treatment infrastructure. Increases in disinfection by-products from increased TOC are unacceptable to the City's residential and institutional water customers such as breweries (Anheuser-Busch, New Belgium and Odell) and high-technology companies (like Kodak and Hewlett-Packard). Treatment of higher TOC levels is very difficult and will require huge increases in capital and operational expenditures by the City to reduce levels of this pollutant as part of the water treatment process.

The addition of higher levels of TOC to Horsetooth Reservoir would create a very high probability of violating state non-degradation standards for Horsetooth Reservoir and would constitute a significant degradation of Horsetooth Reservoir, a Water of the United States. To comply with the Section 404 Guidelines, a discharge of dredged or fill material must not "cause

or contribute to any violations of any applicable state water quality standard. 40 C.F.R. §230.10(b)(1). In addition, no discharge may be permitted that would cause or contribute to "significant degradation of the waters of the United States." *Id.* at §230.10(c).

Regulatory Guidance Letter (RGL) 88-12 emphasizes the importance of the prohibitions listed in Section 230.10(b) and (c) of the Section 404 Guidelines. The RGL states that the Corps should terminate evaluation of a permit application if it determines that the proposal would not comply with the provisions of 40 C.F.R. Section 230.10(b) or (c) (that is, that it would cause or contribute to violation of a state water quality standard or would cause or contribute to significant degradation of the waters).[3]

Any discharge that would "significantly degrade" waters "*can never comply with the guidelines*." RGL 88-12 (emphasis added). Thus, "where an applicant is unable or unwilling to mitigate the adverse effects of a discharge to below the threshold of significance, the application must be denied." *Id.* Effects contributing to significant degradation include "significantly adverse effects" on human health or welfare, including but not limited to effects on municipal water supplies … and special aquatic sites," 40 C.F.R. § 230.10(c)(1), on "recreation, aesthetic, and economic values," *id.* at §230.10(c)(4), and on aquatic ecosystem stability, including "loss of the capacity of a wetland to assimilate nutrients [or] purify water, *id.* at §230.10(c)(3). All of these factors are implicated by the NISP proposal, as discussed in Parts III through V of these Comments.

Further, these impacts will be permanent, because NISP represents a long-term investment in infrastructure that would divert high TOC water to Horsetooth for the foreseeable future. The Section 404 Guidelines direct the Corps, when considering whether a project will contribute to "significant degradation," to place "special emphasis on the persistence and permanence of the effects" of the project. *Id.* at §230.10(c).

Section 5.8.1 of the DEIS does not satisfy the requirements of NEPA or Section 404, because it avoids addressing this critical water quality issue and defers it to an unenforceable and ineffective future. Section 5.8.1 provides first that "the District will comply with future Colorado water quality standards for total organic carbon (TOC)." This an unremarkable promise insofar as it simply states that it will be required to comply with the law. It skirts the critical issue of whether the existing non-degradation standards for Horsetooth would apply, which already forbid the addition of higher TOC water. See Part III of these comments. Section 5.8.1 then provides that:

> If TOC is not regulated by the Colorado water quality program, then 5 years prior to constructing the Glade to Horsetooth pipeline, the District will develop a plan for monitoring TOC in Horsetooth and Glade reservoirs. This plan will be submitted to the Corps and Reclamation for their review and approval. If monitoring indicates that the delivery of water from Glade Reservoir to Horsetooth Reservoir will increase the levels of TOC in Horsetooth Reservoir to

[3] Guidance in regulatory letters that have expired, as has RGL 88-12, "generally remains valid after the expiration date." RGL 05-06, "Expired Regulatory Guidance Letters" ¶2(b). The Corps has specifically identified RGL 88-12 as an expired RGL that is still applicable to the Corps Regulatory Program. *Id.*

> levels determined by Reclamation to be unacceptable, the District will develop a TOC mitigation plan for review and approval by the Corps and Reclamation. Mitigation of TOC levels in Horsetooth Reservoir may include treatment to reduce levels of TOC in water coming from Glade Reservoir or limiting deliveries from Glade Reservoir to Horsetooth Reservoir to times when the deliveries will not result in raising TOC levels in Horsetooth Reservoir to unacceptable levels. Reclamation will incorporate any mitigation requirements for TOC into its approval to connect the pipeline to Horsetooth Reservoir.

DEIS at 5-16.

This approach inappropriately seeks to avoid, delegate and defer addressing the very serious threat to water quality that delivering Glade water to Horsetooth would cause. The extensive data regarding TOC levels from the Poudre watershed and water quality modeling for Glade already show that Glade water would contain much higher levels of TOC than the Horsetooth water used for City drinking water. *See* Section 404 Guidelines at Section 230.50 (effects on the palatability and safety of municipal drinking water).

Because it is already challenging to remove and manage TOC, and because increased TOC causes serious harm to the ability of the City to meet drinking water standards and meet the expectations of customers, the increase in TOC attributable to NISP constitutes significant degradation and is unacceptable. The Corps cannot defer analysis of this issue for unspecified future monitoring or to delegate its obligations under NEPA and the Clean Water Act to the Bureau of Reclamation, which has no role under the Clean Water Act in defining water quality standards. TOC is a pollutant with unquestioned impacts on municipal water supplies and human health. Reclamation has no significant or meaningful history in determining standards for raw drinking water in the area, no information regarding the water treatment processes for the City or other entities and no understanding of the specific needs of local water customers. Delivering water with much higher TOC levels from Glade to the input of the City's system constitutes degradation that must be avoided, minimized and mitigated *now* or the permit application must be denied.

Further, the hypothetical mitigation for TOC identified is just that, hypothetical. The examples of possible mitigation are identified as measures that "may" be included. There is no analysis of whether these measures or others taken could or would eliminate (or even reduce) the detrimental effects of increased TOC water below the threshold of significance (which, the City believes, is degradation from current levels of TOC). There is no analysis of how such measures would affect the cost or benefits of the NISP project. There are no standards to apply and no guarantee that Reclamation would issue standards, let alone ones that address the imperative to protect supplies for City customers. The Clean Water Act requires the Corps to address these issues now, not to issue a permit, see what happens and hope that the criteria of Section 404 are still met.

4b. The DEIS Fails to Meaningfully Address Impacts Associated With Lost Peak Flows

As another example, the DEIS fails to address any of the serious environmental concerns associated with reductions in peak flows in the Cache la Poudre River in Fort Collins. The Supreme Court has confirmed that "reduced stream flow, *i.e.*, diminishment of water quantity, can constitute water pollution" under the Clean Water Act. *PUD No. 1 of Jefferson County and the City of Tacoma v. Washington Department of Ecology* , 511 U.S. 700, 719 (1994). The Court held that the Clean Water Act supports the use of flow requirements as a condition of a Section 404 permit. *Id.* at 724.

> In many cases, water quantity is closely related to water quality; a sufficient lowering of the water quantity in a body of water could destroy all of its designated uses, be it for drinking water quantity, recreation, navigation or as here, as a fishery.... This broad conception of pollution – one which expressly evinces Congress' concern with the physical and biological integrity of water – refutes petitioners' assertion that the Act draws a sharp distinction between the regulation of water quantity and water "quality … Moreover, §304 of the Act expressly recognizes that *water 'pollution' may result from 'changes in the movement, flow, or circulation of any navigable waters … including changes caused by the construction of dams'*. (citation omitted) This concern with the flowage effects of dams and other diversions is also embodied in the EPA regulations, which expressly require existing dams to be operated to attain designated uses."

511 U.S. 700, 719 (1994) (citing 33 U.S.C. §1314(f) and 40 C.F.R. §231.10(g)(4)) (emphasis added).

In addition, the Section 404 Guidelines give the Corps not only the authority, but also the duty, to minimize or mitigate adverse impacts to recreation, water quality, fisheries, habitat, flood conveyance, and aesthetics that result from a permitted activity. The Section 404 Guidelines provide that minimization of adverse effects on "human use potential" may be achieved by, among other things, "in the case of dams, designing water releases to accommodate the needs of fish and wildlife" *Id.* § 230.77(b). The timing of diversions to Glade Reservoir falls into the same category.

As discussed in detail in Parts III through V, the reduction of flows during the Spring and Summer will result in a number of types of significant degradation to the Cache la Poudre and resources relating to it, including but not limited to:

- Deterioration in water quality to a level that would cause algal blooms and fish kills in some locations;
- Increases in water temperature that would eliminate some species of fish and macroinvertebrates from portions of the river;

- Accelerated sedimentation that would threaten stream habitat and flood-water conveyance;
- Reduced flows and groundwater recharge, threatening riparian vegetation and wildlife that depends on it;
- Increased threats of invasive weeds and other species;
- Increased risk of trichloroethylene contamination in the river;
- Damaged or lost recreational fisheries; and
- Reduced flows that would impair recreational uses such as boating.

Despite all of these forms of substantial degradation, the DEIS does not offer or analyze adequate avoidance, minimization or mitigation, as required by the Section 404 Guidelines. Even where the DEIS identifies purported mitigation, it falls far short of the Corps' obligations under Section 404.

For example, Section 5.1.6 of the DEIS suggests:

> The District will also develop a plan to be approved by the Corps for periodically curtailing diversions from the Poudre River for at least 24 hours during high flows, which could provide the riparian areas with periodic disturbance and inundation. The diversion curtailment plan will be implemented provided the District and Corps can be assured that the passed water will flow to at least I-25 and not be diverted by junior appropriators.

However, this very general suggestion lacks information regarding the criteria for the development for the plan (e.g., the biological criteria that would indicate success), the ability to meet the I-25 and junior appropriator criteria, any information about the extent and duration of needed flows, the basis for the identified 24-hour period, the duration of possible curtailment of diversions, and other factors that would allow the Corps or the public to evaluate whether the proposed mitigation would have a meaningful effect in reducing the significant degradation to the riparian resources. Further, there is no legal basis for the arbitrary and self-imposed criterion that curtailed diversion flows would need to reach at least I-25. If curtailed diversion would avoid, minimize or mitigate significant deterioration to locations short of I-25, the Corps cannot arbitrarily eliminate the measure.

Similarly, proposals in Section 5.1.6 of the DEIS to "identify areas suitable to plant native woody riparian vegetation and disturb decadent stands of woody riparian vegetation to help compensate for the reduction in disturbance from reduced overbank flows" is incomplete at best. It does not address the root problems associated with the loss of riparian flushing and watering flows that are necessary for a healthy riparian ecosystem and, therefore, risks failure of the proposed plantings. Further, it does not commit to any particular plantings or maintenance that would be necessary to provide any assurance that any mitigation would actually occur. Any plantings and maintenance needed to compensate for the damages from NISP should be paid for by the project proponents. No analysis is provided of the extent to which the measure would be effective or would compensate for the serious harms that riparian vegetation are likely to experience from NISP. *See* Sections IV.3 and IV.4 of these Comments.

In Section 5.2.3, the DEIS makes the following claim in an attempt to partially address the

serious recreational and ecological impacts from reduced flows in the City:

> The District will seek an agreement with the Lake Canal Company to move diversions from the Lake Canal intake on the Poudre River near College Avenue to the Timnath Reservoir Inlet Canal about 3 miles downstream. On average, moving the diversions from the Lake Canal downstream would add about 50 cfs to the Poudre River for 6 weeks from late May to early July. The District does not control the water diverted by the Lake Canal, but will work with the canal company and any opposers to the change in diversion location to accomplish the change. Relocating this diversion point would allow for higher flows in the Poudre River through the City of Fort Collins, which would reduce some of the recreational impacts expected to otherwise result from the action alternatives.
> The District will also explore agreements with other water providers to retime their direct flow rights by temporarily storing water in Glade Reservoir and/or its forebay for release during late July and August. Such agreements would add to the flows of the Poudre River through Fort Collins during the summer.

Again, while this gesture points in the right direction, it falls far short of the Corps' Section 404 and NEPA obligations. All of the suggestions that the District "will seek," "will work" and "will [ ] explore" changes in the location of diversions falls fall short of showing that this partial mitigation would be achieved. There is no guarantee of any additional flows. Similarly, there is no analysis of the levels of flow necessary to preserve recreational options or ecological functions or the extent to which an average of 50 cfs meets this need. While returning 50 cfs would undoubtedly have some benefit, it would fall far short of the up to 71 percent reductions in flows contemplated by NISP and appears insufficient to address impacts to recreation. Again, there is no evidence or analysis of the proposed (unenforceable and unreliable) measure and the recreational, ecological and other values the Corps is obligated to protect.

The DEIS (at Section 5.7) also proposes a "monitoring and adaptive management program" to study various elements of stream morphology; under the adaptive management program "several mitigation measures may be available" – one of which is "regulate flows and utilize exchanges to promote the increase in water level to support adjacent riparian vegetation and other river attributes." DEIS at 5-15. As discussed below in Section II.5, this represents a misuse of the adaptive management concept and does not comply with the Corps' Clean Water Act or NEPA obligations. Even aside from the adaptive management label, the proposal is so vague as to be meaningless. There is no definition of the criteria for stream morphology impact or significance, no criteria for success and no analysis of the extent to which any of the possible – not committed – measures would actually address the serious impacts to stream morphology discussed in Part IV of these Comments. *See* Section IV.1.

4c. Section 101(g) of the Clean Water Act Does Not Diminish the Corps' Obligations under Section 404

Section 101(g) of the Clean Water Act, the so-called Wallop Amendment, does not in any way diminish the Corps' obligations to avoid, minimize and mitigate under Section 404. Section

101(g) provides that the states' water allocation authority "shall not be superseded, abrogated, or otherwise impaired," and nothing in the Clean Water Act "shall be construed to supersede or abrogate rights to quantities of water which have been established by any state."

The Supreme Court considered the meaning of Section 101(g) in *PUD #1*, and held that, while it preserves that authority of each state "to allocate water quantity *as between users*," it does *not* "limit the scope of water pollution controls that may be imposed on users who have obtained, pursuant to state law a water allocation." 511 U.S. at 720 (emphasis added). Moreover, Congress understood full well that protection of aquatic resources would have "incidental effects" on state-authorized water effects. *Id.* at 721 (citing the legislative history of the Amendment: "The requirements [of the Act] may incidentally affect individual water rights … it is not the purpose of this amendment to prohibit those incidental effects").

In *Riverside Irrigation Dist. v. Andrews*, the Tenth Circuit determined that, in implementing Section 404 of the CWA, the Corps was required to consider impacts on endangered species from reduced flows caused by a new dam could affect whooping crane habitat far downstream of the dam. The court held that Section 101(g) could not "nullify" the clear dictates of the Endangered Species Act or the Clean Water Act: "Congress did not intend to limit 404's scope where it might affect state water-rights law when it enacted §101(g)." 568 F. Supp. 583, 589 (D. Colo. 1983), *aff'd* at 758 F.2d 508 (10th Cir. 1985). Indeed, the issue in the case "is reduced to the Engineer's statutory authority to control of the quantity of water released." *Id.* at 587. And the court held that the Engineer did have authority over water quantity, in the interest of effecting the other obligations imposed by the Clean Water Act:

> Although the [District Engineer]'s actions may have a substantial effect on state water rights, such is the case with many federal laws which particularly preempt state water laws. For example, a congressional designation of a river as wild or scenic under the Wild and Scenic Rivers Act, … will bar most dams and other diversion works from being constructed on the designated section, often limiting the exercise of state water rights. Yet this act has not been successfully challenged as an improper intrusion on state water rights.

Id.

The cases that have examined Section 101(g) have distinguished between "incidental effects" of a permitting decision and actions that are directly intended to affect water rights. In *United States v. Akers*, 785 F.2d 814 (9th Cir. 1986), and again in *PUD #1*, courts held that "incidental effects" on state water rights did not implicate the Wallop Amendment. Senator Malcolm Wallop, the sponsor of the Wallop Amendment, described the purpose of the amendment as follows:

> The requirements of section 402 and 404 permits may incidentally affect individual water rights.... It is not the purpose of this amendment to prohibit those incidental effects. It is the purpose of this amendment to insure that State allocation systems are not subverted, and that *effects on individual rights, if any, are prompted by legitimate and necessary water quality considerations.* This

> amendment is an attempt to recognize the historic allocation rights contained in State constitutions. It is designed to protect historic rights from mischievous abrogation by those who would use an act, designed solely to protect water quality and wetlands, for other purposes. *It does not interfere with the legitimate purposes for which the act was designed.*

3 Leg. Hist. 532 (Senate Debate, Dec. 15, 1977) (emphasis added). Thus, according to the provision's sponsor, Section 101(g) is designed to protect water rights from "mischievous abrogation" by those who would misuse the Clean Water Act's provisions for purposes *other than* protecting water quality and wetlands. The amendment is not intended to interfere with the Clean Water Act's "legitimate purposes." As such, the Corps retains authority – and in this case the obligation – under Section 404 to regulate water *flows* in order to fulfill its obligation to protect water *quality*.

Without addressing the obligations to avoid, minimize and mitigate the extensive and serious impacts of the proposed action, the Corps cannot issue a permit under Section 404. Indeed, the pervasive deficiencies of the DEIS require an SDEIS that would, among other things, adequately address the requirements of the Clean Water Act.

5. The DEIS's Use of Adaptive Management Is Inappropriate and Inadequate

One category of the DEIS's inadequate avoidance, minimization and mitigation "commitments" – adaptive management – merits its own consideration. The DEIS makes extensive use of claimed "adaptive management" approaches in an attempt to avoid any real analysis of the extent to which NISP impacts can be adequately avoided, minimized and mitigated. However, the DEIS's use of adaptive management is improper and inadequate to satisfy the Corps' Section 404 obligations. The proposed "adaptive management" provisions lack any meaningful performance objectives, criteria, implementation guarantees and analysis of effectiveness.

Adaptive management can have a legitimate place as part of an avoidance, minimization and mitigation plan, but it is not mitigation in and of itself. 73 Fed. Reg. 19,594, 19647 (Apr. 10, 2008) ("An adaptive management plan is part of a mitigation plan …, not a substitute for a complete mitigation plan."). Caselaw, agency guidance and technical guidance on adaptive management all make clear that it is not intended to serve as a license for a "trial and error" form of management. *E.g.*, U.S. Dep't. of the Interior, *Adaptive Management Technical Guidance* vii (2007) ("It is not a 'trial and error' process…"). Instead, it is an addition to the early forms of NEPA process that followed a "predict-mitigate-implement" form of management. *See e.g.*, Council on Environmental Quality NEPA Task Force, *Modernizing NEPA Implementation* at 45 (Sept. 2003) ("*NEPA Implementation*"). Adaptive management adds monitoring and adaptation to the end of the process to form a "predict-mitigate-implement-monitor-adapt" process. *Id.*

Nothing about adaptive management minimizes the need for the Corps to fully comply with the critical "predict-mitigate-implement" part of the process that is still required by the Clean Water Act and NEPA.

> To successfully use the "predict, mitigate, implement, monitor, and adapt" model in the NEPA process, the *potential impacts of the proposed adaptive actions must be considered before implementation*. Therefore, the "predict" step of the model must include an analysis of the potential impacts of the proposed adaptive actions. When the actions or new conditions exceed the scope of the original analysis, new or supplemental NEPA review is necessary.

NEPA Implementation at 48. Further, the process requires "[t]echnically and scientifically credible performance measures or thresholds used to assess progress and effects, and quality control measures that ensure the integrity and appropriateness of the adaptive management approach." *Id.* at 49.

> Generally, the NEPA document should describe:
> - The proposed adaptive management approach;
> - How the approach is reflected in the alternatives being considered;
> - The monitoring protocol;
> - The desired outcome;
> - The performance measures that will determine whether the desired outcome is being achieved or an adaptive action is needed; and
> - The factors for determining whether additional NEPA review is needed.

Id. at 52. *See also*, Council on Environmental Quality, *Aligning National Environmental Policy Act Processes with Environmental Management Systems* at 13 (Apr. 2007) ("An essential component of the adaptive management model (*i.e.*, predict, mitigate, implement, monitor, and adapt) is monitoring to assess whether predictions of environmental effects are correct, and that any mitigation is functioning as intended."); 73 Fed. Reg. 21468, 21512 (Apr. 21, 2008) (Forest Service national forest planning rule) ("Adaptive management: A system of management practices *based on clearly identified outcomes* and monitoring to determine if management actions are *meeting desired outcomes*…) (emphasis added).

The recently-issued Corps and EPA regulations for compensatory mitigation make clear the necessity of these elements for adaptive management as part of a mitigation plan. 73 Fed. Reg. 19594 (Apr. 10, 2008). "An adaptive management plan is part of a mitigation plan …, not a substitute for a complete mitigation plan." 73 Fed. Reg. at 19,647. "The focus of adaptive management should be on taking measures to *achieve performance* and *satisfy the objectives* of the compensatory mitigation project." *Id.* (emphasis added). Thus, adaptive management depends on having defined impacts (even with acknowledged uncertainty) and a concrete plan for mitigating these impacts. The core focus is on identifying with specificity and ensuring certain objectives and defined through performance measures. *Id.* at 19,648; 33 C.F.R. § 332.5 ("Performance standards must be based on attributes that are objective and verifiable. Ecological performance standards must be based on the best available science that can be measured or assessed in a practical manner.").

> Adaptive management means the development of a management strategy that anticipates likely challenges associated with compensatory *mitigation projects*

> and provides for the implementation of actions to address those challenges, as well as unforeseen changes to those projects. It requires consideration of the risk, uncertainty, and dynamic nature of compensatory mitigation projects and guides *modification of those projects to optimize performance*. It includes the selection of appropriate measures that will *ensure that the aquatic resource functions are provided* and involves analysis of monitoring results to identify potential problems of a compensatory mitigation project and the identification and implementation of measures to rectify those problems.

33 C.F.R. § 332.2 (emphasis added).

The Corps' regulations clarify that adaptive management relies on the monitoring to determine whether the already-committed mitigation project is meeting its objectives as measured by the specific performance standards identified as part of the initial planning and development of a mitigation plan. *Id.* § 332.7(c). The Corps' civil works policies have a similar focus, in which monitoring and adaptive management are aimed at ensuring "predicted" or "proposed outputs." *E.g.*, Engineer Regulation 1105-2-100, § 3-8(b)(8). There is no reasonable, non-arbitrary basis for the Corps to vary the concept of adaptive management among its Section 404 compensatory mitigation program, its civil works policy and the rest of the Section 404 process.

Courts have struck down attempts to insert vague measures that do not meet the "predict, mitigate and implement" requirements of NEPA and the Clean Water Act identified above. For example, the Southern District of New York found that adaptive management in a Corps EA for a harbor deepening project was inadequate:

> The EA also explains that the Corps will follow "adaptive management practices as it moves through construction of its contracts," thus allowing it to change future contracts should the data indicate it is necessary. These promises, however, provide no assurance of as to the efficacy of the mitigation measures. The Corps did not provide a proposal for monitoring how effective "adaptive management" would be.

Natural Resources Defense Council v. Army Corps of Engineers, 457 F.Supp.2d 198, 234 (S.D. N.Y. 2006). *See also, High Sierra Hikers Ass'n v. Weingardt*, 521 F.Supp.2d 1065, 1091 (N.D. Cal. 2007) (Forest Service's use of adaptive management violated Wilderness Act and NEPA; "Forest Service failed to adequately consider warnings from adjacent wilderness areas about its campfire policy and improperly relied on adaptive management to control the campfire policy. This demonstrates that the Forest Service failed to take a hard look as required by NEPA…").

Similarly, the Eastern District of California recently found that the adaptive management provisions in a biological opinion issued by the Fish and Wildlife Service for a water diversion operating plan failed to provide reasonable certainty to assure that mitigation would be implemented, as required by the Endangered Species Act:[4]

[4] The Endangered Species Act requirements are functionally identical for these purposes to the mandatory Clean Water Act avoidance, minimization and mitigation obligations.

> Here, the adaptive management process has *no quantified objectives or required mitigation measures*. Although the process must be implemented by holding meetings and making recommendations, nothing requires that any actions ever be taken. The BiOp asks the court to trust the agency to protect the species and its habitat. Notwithstanding any required deference to expertise, the ESA requires more.
>
> All parties agree that adaptive management can be beneficial and that flexibility is a necessary incident of adaptive management. The law requires that a balance be struck between the dual needs of flexibility and certainty. The [plan], as currently structured, *does not provide the required reasonable certainty to assure appropriate and necessary mitigation* measures will be implemented. … This aspect of the BiOp is arbitrary and capricious as a matter of law.

Natural Resources Defense Council v. Kempthorne, 506 F.Supp.2d 322, 356 (E.D. Cal. 2007) (emphasis added).[5]

In a similar way, the adaptive management provisions in the DEIS fail to comply with the requirements of the Clean Water Act and NEPA. They are vague, lack performance standards and criteria for success, and provide no real mitigation plan that would be managed in an adaptive way. They fail to supply the plan and mitigate portions of the process, which are critical omissions. Thus, the DEIS's proposals are not really adaptive management, but instead deferred management or trial and error management, neither of which are permitted under the Clean Water Act.

For example, as discussed in Section II.4 above, the DEIS (at Section 5.7) proposes a "monitoring and adaptive management program" to study various elements of stream morphology; under the adaptive management program "several mitigation measures may be available" – one of which is "regulate flows and utilize exchanges to promote the increase in water level to support adjacent riparian vegetation and other river attributes." DEIS at 5-15. This proposal represents a misuse of the adaptive management concept and does not comply with the Corps' Clean Water Act or NEPA obligations. As in the provision struck down in *Kempthorne*, there is no definition of the criteria for impact or significance, no criteria for success and no analysis of the extent to which any of the proposed – not committed – measures would actually address the serious impacts to stream morphology discussed in Part IV of these Comments. As discussed in Section IV.1, the DEIS fails even to predict the probable impacts, let alone identifying a plan to address the impact. Without proper diagnosis a proper treatment is very unlikely. An SDEIS must be prepared that (1) fully addresses the impacts associated with

[5] It is instructive to compare these cases to ones in which adaptive management or its equivalent has been upheld. For example, in *Holy Cross Wilderness Fund v. Madigan*, 960 F.2d 1515 (10th Cir. 1992), the Corps issued a Section 404 permit before completion of studies designed to develop a mitigation plan for adverse impact on wetlands, (and, because studies and plan were not completed, issued the permit before full public review of results). The permit was conditioned on a requirement that no wetlands be lost, and on a requirement that a Monitoring and Mitigation Plan be developed to ensure there would be no loss of wetlands. The court rejected a challenge to the permit-first-mitigate-later approach to the 404 permit because the permit "specifically stated that no wetlands losses would be allowed, and that a mitigation plan would have to be developed to ensure that result." There is no comparable commitment to avoid impacts to wetlands and other resources in the NISP context.

sedimentation; (2) provides a real, committed avoidance, minimization and mitigation plan; and (3) analysis of the effectiveness of these measures.

The same deficiencies are present in the DEIS's proposed mitigation of TOC impacts to Horsetooth Reservoir and the City's water supplies. As discussed above in Section II.4b, the proposed "mitigation" measures for TOC defer assessment of impact, identification of thresholds for significance and a mitigation plan until after permit issuance. This approach would not be appropriate adaptive management and would violate the Clean Water Act and NEPA.

6. Because of the DEIS's Failure To Provide Sufficient Analysis of the Impacts of the Proposed Permit and Address Their Avoidance, Minimization and Mitigation, A Supplemental Environmental Impact Statement Is Necessary To Comply With NEPA and the Clean Water Act

NEPA specifically requires a "detailed statement" of the environmental impact of the proposed action. 42 U.S.C. §4332(2)(C). The primary function of this detailed statement is to insure "a fully informed and well-considered decision." *Vermont Yankee Nuclear Power Corp. v. Natural Resources Defense Council, Inc*., 435 U.S. 519, 558 (1978). In order to fulfill its role, the EIS must set forth sufficient information for the general public to make an informed evaluation. *Sierra Club v. United States Army Corps of Engineers*, 701 F.2d 1011, 1029 (2nd Cir. 1983).

In so doing, the EIS insures the integrity of the decisionmaking process "by giving assurance that stubborn problems or serious criticisms have not been 'swept under the rug.'" *Silva v. Lynn*, 482 F.2d 1282, 1285 (1st Cir. 1973). This requires a level of detail that makes it possible for the decisionmaker to "consider fully the environmental factors involved and to make a reasoned decision after balancing the risks of harm to the environment against the benefits to be derived from the proposed action." *Sierra Club*, 701 F.2d at 1029 (quoting *county of Suffolk v. Secretary of Interior*, 562 F.2d 1368, 1375 (2nd Cir. 1977).

CEQ regulations governing implementation of NEPA state that a draft impact statement "must fulfill and satisfy to the fullest extent possible the requirements established for final statements in [§4332(2)(C) of NEPA]." 40 C.F.R. §1502.9. Moreover, the regulations require that an insufficiently detailed DEIS be supplemented or revised: "*if a draft statement is so inadequate as to preclude meaningful analysis, the agency shall prepare and circulate a revised draft of the appropriate portion.*" *Id (emphasis added).*

The Corps has also adopted procedures at 33 C.F.R. Parts 230 and 325 for implementing NEPA, which are intended to supplement the CEQ regulations. *See* 33 C.F.R. §230.1 (Corps regulations supplement and should be used in conjunction with the CEQ regulations). These regulations also require a detailed discussion of the environmental impacts of the proposal and alternatives. *See* 33 C.F.R. Part 325, App. B (citing 40 C.F.R. §1502.16).

Courts have interpreted these regulations to require that an impact statement must contain an adequate compilation of relevant information. *Sierra Club*, 701 F.2d at 1031. Where the statement failed to do this, the agency's subsequent decision lacked a "substantial basis in fact" and "a decisionmaker relying on [the inadequate EIS] could not have fully considered and balanced the environmental factors." *Id.*

Accordingly, courts have rejected environmental impact statements when they fell short of the level of detail required by the statute and regulations. *See e.g.*, *Westlands Water Dist. v. Dept. of the Interior*, 275 F.Supp.2d 11571198 (E.D. Cal. 2002) ("An SEIS is required for the Trinity Dan bypass RPM because Interior did not analyze or address the measure and its impacts on Northern California power supply and reliability in the DEIS."). In *Silva v. Lynn*, the First Circuit found that an FEIS submitted by the Department of Housing and Urban Development ("HUD") fell "far short of what is required," 482 F.2d at 1285, and could not serve to fulfill NEPA's mandate. *Id.* at 1287. The FEIS, concerning a proposed housing project, glossed over some of the department's key decisions without sufficient discussion:

> The project's site contains a low wetland portion in and near an area where the water table is high. Adjacent lower lying areas have historically experienced chronic flooding. This is plainly a major problem. We think it is not too much to ask that the problem be fully depicted, that HUD describe the approach that was taken, and the reasons why the particular mode of control was chosen in preference to others.

Id. In addition, the relevant section of the Draft EIS had drawn "heavy fire, as being wholly inadequate," from other federal agencies with more expertise in drainage than HUD, but the FEIS barely acknowledged the comments. *Id.* at 1286. The court also rejected as inadequate HUD's dismissal of some of the alternatives as being "economically unsound." *Id.* The agency "must go beyond mere assertions and indicate its basis for them." *Id.* As with the drainage problems, "what the courts look for is an informed and adequately explained judgment." *Id.* at 1287. *See also Johnston v. Davis*, 698 F.2d 1088 (10th Cir. 1983) (EIS inadequate and must be supplemented because of misleading, unqualified statements about likely economic value of project).

In a previous case involving a proposed dam, the court found the EIS provided insufficient detail regarding geological instability under the dam site, the proposed dam's effect on groundwater quality, and the likely effects on wildlife. *Save the Niobrara River Ass'n v. Andrus*, 483 F. Supp. 844 (D. Neb. 1979). For example, the agency doing the EIS – the Bureau of Reclamation – concluded there would be minimal impact on groundwater quality, but the conclusion was not based on scientific studies, and the court found the discussion and data concerning the expected impact on groundwater to be inadequate under NEPA requirements. *Id.* at 853.

Another court found an EIS regarding a proposed watershed project to have an inadequate discussion of the impact of sediment that would be carried downstream as a result of the project. *NRDC v. Grant*, 355 F. Supp. 280, 287 (D. N.C. 1983). The EIS disclosed the increased sediment load, but did not provide an adequate discussion of its downstream effects: "The Statement merely concludes, without supportive scientific data and opinion, that 'No significant

reduction in quality of the waters [downstream] is expected.' … Having conceded a massive increase in sedimentation, the Statement disposes of its environmental effects in one conclusory statement unsupported by empirical or experimental data, scientific authorities, or explanatory information of any kind." *Id.* In addition, the statement suggested there would be some effects on fish in the watershed, but then declared "without any supportive data" that "Most of the fishery resources in the watershed will not be affected …or will be mitigated." *Id.* This fell "far short" of NEPA's requirements. *Id.*

The Clean Water Act also requires the Corps to supplement a DEIS if it does not contain sufficient information in sufficient detail to comply with the requirements of the Section 404 Guidelines. *Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1163 (10th Cir. 2002). ("If, however, the NEPA documents do not consider the alternatives in sufficient detail to respond to the requirements of the Guidelines, it may be necessary to supplement NEPA documents with additional information. 40 C.F.R. § 230.10(a)(4)."). *See also Louisiana Wildlife Federation v. York*, 761 F.2d 1044, 1051 (5th Cir. 1985) (supplement necessary where information "presents a seriously different picture of the environmental impact of the proposed project from what was previously envisioned").

As detailed in the comments contained in Parts III through V, the DEIS suffers from fatal deficiencies that prevent it from fully disclosing and addressing the impacts of the proposed action. In order to comply with the applicable regulations and to fulfill the requirements of NEPA and the Clean Water Act – to provide sufficient information so that decisionmakers can make a fully informed choice between the alternatives – the DEIS must be supplemented. If the Corps were to proceed directly to an FEIS with no circulation of an SDEIS, the FEIS would itself be inadequate. *Utahns for Better Transportation v. USDOT*, 305 F.3d at 1163; *Louisiana Wildlife Federation v. York*, 761 F.2d at 1051. The full and accurate disclosure of the missing information called for in the City's comments would constitute "significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts" and, as such, would mandate that a SDEIS be prepared. 40 CFR § 1502.9(c)(1).

The DEIS and its technical appendices do not contain complete operational plans for the NISP project. The City of Fort Collins made two requests for supplemental information, by letters from its outside counsel dated May 7, 2008 and June 4, 2008, specifically including requests for operations data and delivery schedules for NISP. This data has not been supplied, and thus the operational impacts of NISP have not been fully disclosed or described in the DEIS.

Finally, in an August 19, 2008 meeting between the District, the City and others, the District's project manager for NISP suggested that the District was considering a completely new and different project concept consisting of pumping NISP water from the Poudre River to Glade and releasing water from Glade, then piping the water from the River to Horsetooth. Such a change in project plans, if carried forward, would constitute a "substantial change[s] in the proposed action that [is] relevant to environmental concerns" and therefore require that an SDEIS be prepared and circulated for public review and comment. 40 CFR § 1502.9(c)(1).

7. The Corps May Not Segment or Defer Its Analysis of the Impact of the Glade-Horsetooth Pipeline

Throughout the DEIS, the Corps has sought to defer its analysis of the impacts and compliance with the Section 404(b) Guidelines relating to the construction of the Glade-Horsetooth Pipeline. This is inconsistent with the Corps' obligations under both NEPA and Section 404 and substantively critical, because of the serious degradation to water quality that would result from the pipeline. *See* Section III.1 of these Comments.

The Corps may not segment its analysis of the Glade-Horsetooth Pipeline from the rest of NISP, because it is an integral part of the long-term feasibility of the project. The Northern Colorado Water Conservancy District's Individual Permit Application for NISP explicitly includes the pipeline as part of the overall project. *See* Application for Department of the Army Permit, Northern Integrated Supply Project Supplemental Information for Application for U.S. Army Corps of Engineers Section 404 Individual Permit at 2, 3, Figure 2 and Figure 13 (Apr. 24, 2008). "A pipeline connecting the proposed Glade Reservoir to the existing Horsetooth Reservoir is proposed to be constructed." *Id.* at 2.

The overall project depends on having this pipeline and/or another pipeline to Horsetooth or Carter Reservoirs to deliver project water to participants that cannot draw water from the Poudre River. The DEIS claims that the project may be able to work without the pipeline in the short term due to the potential for Colorado-Big Thompson ("C-BT") water exchanges, whereby current holders of C-BT shares in the Poudre watershed would take project water from Glade instead of C-BT water and their C-BT water taken by NISP participants. However, there will be insufficient water for such exchanges by 2020, so that a pipeline to Horsetooth or Carter Reservoir will be needed to meet the project purpose and need.

The District's April 2008 Water Delivery Report shows that just fewer than 60,000 C-BT units are owned by entities that have C-BT water delivered to the Poudre River. Of this, about 28,000 units are owned by municipalities through ownership of North Poudre Irrigation Company shares. This results in about 32,000 owned units available for delivery of water to the Poudre River. Based on annual delivery quotas from 50% to 100%, this translates into a range of 16,000 acre feet to 32,000 acre feet available for potential exchanges on the Poudre River. In addition to this, there may be a limited amount of municipally owned C-BT water available for rental to agricultural users and delivered to the Poudre. There has been, however, a clear trend of C-BT units being transferred from agricultural owners to municipal owners with less C-BT water becoming available for agricultural use. *See e.g.*, District, *NISP Phase II Alternative Evaluation* at ES-5 (Jan. 2004) (showing reduction in agricultural C-BT units by over 50% after 2020). Considering these factors, there will not be adequate C-BT water available in the Poudre Basin to accomplish the exchange referred to in DEIS Section 2.3.3.1 to meet the 29,500 acre feet of demand by the southern NISP Participants. This will necessitate the Glade-Horsetooth Pipeline or a Glade-Carter Pipeline if NISP is to operate as claimed.

Because the purpose and need for the project is to ensure the firm yield until at least 2050, the pipeline is an essential part of the overall project as it has been defined and must be fully analyzed now. Failure to do so would constitute illegal segmentation under both NEPA and

Section 404. The pipeline is a connected action under the Council on Environmental Quality regulations governing NEPA compliance: the construction of the Glade Reservoir would automatically trigger the need for the pipeline, NISP would not proceed if there were no way to get project water from Glade Reservoir to either Horsetooth or Carter Reservoirs, and the pipeline and Glade Reservoir are interdependent parts of a larger action and depend on the larger action for their justification. 40 C.F.R. § 1508.25(a)(1).

However, as discussed in greater detail in Part III, the DEIS does not provide meaningful analyses of the water quality impacts of the pipeline and completely fails to provide meaningful measures to address these impacts pursuant to Section 404.

Part III - Water Management Effects

1. Source Water and Drinking Water Treatment

1a. Comments on DEIS

DEIS Section: 1.8.1 Relationship to Other Water Supply Projects, page 1-47
Statement: *"NISP also could be physically linked to other existing facilities such as Horsetooth Reservoir* ***or the Pleasant Valley pipeline****, which could be used to convey NISP water." [Italics added]*.

Comment: Since the City receives water through the Pleasant Valley Pipeline (PVP), any direct delivery of Glade water into the PVP is likely to impair the water quality of sources treated by the City. As discussed below in the comments on DEIS Sections 4.5.1 and 4.5.5, all available evidence indicates that Glade water would have much higher levels of Total Organic Carbon (TOC) and other contaminants that would impair the raw water supply used by the City for drinking water.

No details regarding the possible connection to the PVP is provided anywhere in the DEIS and associated Technical Reports. The full impact of this connection to the City cannot be assessed without modeling specific delivery schedules and their associated water quality parameters. However, it must be stated that certain operational scenarios like those stated on page 1-47 of the DEIS could have significant cumulative impacts on water treatment processes, operating costs and finished water quality.

In order to comply with Sections 230.22 and 230.50 of the Section 404(b)(1) Guidelines, the Corps must evaluate in an SDEIS and Revised Section 404(b)(1) Analysis, and must address the impacts of the proposed project on municipal water supplies like those of the City, including the effect of introducing Glade water to the PVP in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 2.3.3.1 Reclamation Contract Subalternative, page 2-27
Statement: *"The proposed exchange involves the annual delivery of 29,500 AF from Carter Lake to the NISP southern Participants, with equivalent replacement water to be released (1) from Glade Reservoir directly to the Poudre River to meet C-BT irrigation needs, (2) directly from Glade Reservoir into the Munroe Canal, or (3) delivered by pipeline to Horsetooth Reservoir."*

Comment: Implementing the above-described exchanges will cause an annual average reduction 29,500 acre-feet of west-slope water flowing into Horsetooth Reservoir. These reduced inflows would negatively impact the quality of water stored in Horsetooth Reservoir.

These adverse water quality impacts must be evaluated and fully addressed in an SDEIS and Revised 404(b)(1) Analysis under Section 230.50 of the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 2.3.3.2 Reclamation No Contract Subalternative, page 2-27
Statement: *"For deliveries from Glade Reservoir, the Reclamation No Contract Subalternative would include the construction of a pipeline to the south (the proposed Carter pipeline) to connect Glade Reservoir to the existing Southern Water Supply Project (SWSP)."*

Comment: The Glade-to-Carter pipeline option would avoid or minimize potential adverse water quality impacts to the City's drinking water sources that are discussed in these Comments. This is the best option for delivery of NISP water to participants, if NISP is built, and necessary to avoid or minimize impacts to City municipal drinking water supplies. The proposed pipeline must also include a direct connection to the Soldier Canyon Filter Plant to avoid potential blending of Glade water and Horsetooth water in the Pleasant Valley Pipeline (PVP).

DEIS Section: 3.5.2.1 Cache la Poudre River, page 3-28
Statement: *"The water quality of the Cache la Poudre River ranges from nearly pure mountain runoff upstream …"*

Comment: Diversions from the Poudre River to Glade Reservoir will occur during periods of high flow - the May through June snowmelt runoff period. Because the District proposes to mix project water under some circumstances with the municipal drinking water supplies of the City in Horsetooth Reservoir, the quality of water within the Upper Cache la Poudre River during this time must be more thoroughly and carefully considered. The NISP DEIS Water Quality Technical Report (ERO and HDR, March 2008) presents a time series plot of Total Organic Carbon (TOC) concentrations in the Poudre River near the Canyon Mouth (Figure 8, page 80), but there is no discussion of the significance of these data in Section 3.5.2.1 of the DEIS.

Such a discussion is necessary in an SDEIS to comply with the Corps' obligations under both Section 404 and NEPA to fully evaluate the effects of the proposed permitting action on water chemistry and municipal water supplies. It must be emphasized that TOC concentrations reach their highest levels during the spring runoff period when Glade Reservoir would be filled.

In the Poudre River watershed, leaching of soil and land cover organic matter during spring snowmelt results in the TOC levels rising with the snowmelt hydrograph. During the six to eight week snowmelt runoff period, TOC concentrations in the Upper Poudre start at a baseline of about 2 mg/L, rise to a peak that in most years ranges between 8 and 12 mg/L, and then gradually fall back down to the baseline (Billica, Loftis, and Moore, 2008; Loftis and Moore, 2007a). As described in the comments (below) regarding DEIS Section: 4.28.2.1 Water-Based Actions, page 4-104, and the Executive Summary, page ES-14, the peak TOC concentration is generally related to the moisture content of the snowpack prior to runoff, with drought years resulting in lower peak TOC concentrations. So, Poudre River TOC concentrations are expected to be highest during the wet years when diversions are made from the Poudre River to Glade Reservoir.

High TOC concentrations in waters of the Upper Poudre River during the spring snowmelt runoff period have historically presented a significant treatment challenge and higher treatment costs at the Fort Collins Water Treatment Facility (FCWTF). Hence, the storage of high TOC

water in Glade Reservoir and the subsequent transfer of this water into Horsetooth Reservoir is a significant concern for the City and a fundamental issue that the Corps must address under the Section 404(b)(1) Guidelines.

TOC is detrimental to the City because it hinders the optimization and efficiency of water treatment unit operations, including coagulation and settling, and serves as the main building-block for the formation of disinfection by-products (DBPs). DBPs are potential carcinogens formed when TOC reacts with chlorine used for disinfection. Trihalomethanes (such as chloroform) and haloacetic acids (such as trichloroacetic acid) are two groups of DPBs that can be formed during chlorination. Treated water delivered from the FCWTF must not exceed Maximum Contaminant Levels (MCLs) for these two groups of DPBs as set forth in the US EPA Disinfectants/Disinfection By-Products Rule (USEPA 1998, 2001). These regulations also require the removal of TOC to minimize DBP formation if raw water TOC concentrations are greater than 2.0 mg/L. TOC removal and DBP formation both depend on the nature, composition, structure, and reactivity of the various organic compounds that make up the TOC in the raw water.

Because high TOC levels can result in corresponding high levels of potential cancer-causing contamination of the City's drinking water, they must be fully addressed pursuant to the Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 3.5.2.1 Cache la Poudre River, page 3-28
Statement: "*The quality of the North Fork of the Poudre River is somewhat poorer than the mainstem, with temperatures that occasionally exceed the standard and elevated dissolved solids concentrations.*"

Comment: In addition to the North Fork water quality characteristics identified in Section 3.5.2.1, the North Fork has TOC concentrations that are consistently higher than those on the main stem (Lewis, 2001-2007; Loftis and Moore, 2007b; Billica, Loftis, and Moore, 2008).

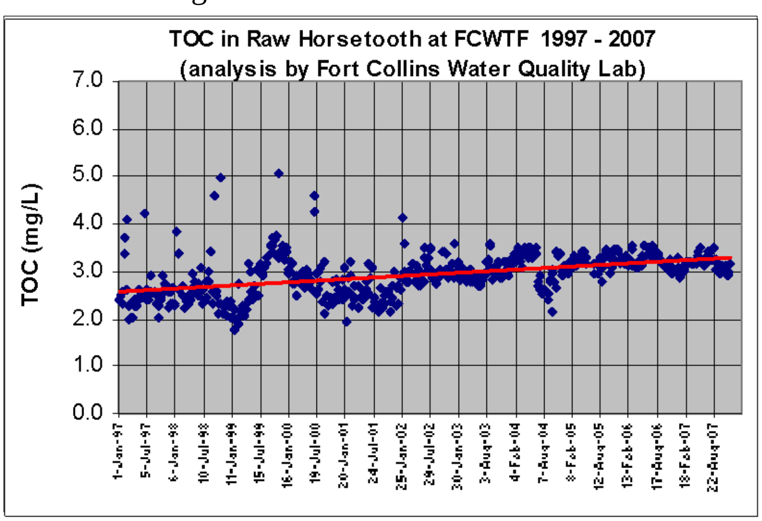
Also, the taste and odor compound, geosmin, has been detected in the North Fork reservoirs (Seaman Reservoir and Halligan Reservoir) at very high concentrations. Geosmin is one of the most difficult taste and odor compounds to remove during water treatment. It is a naturally occurring organic compound produced by blue-green algae (Cyanobacteria). When these organisms die and decompose, geosmin is released into the water. Geosmin imparts a moldy-earth, boiled raw beets odor to water and can be detected by the most sensitive noses at extremely low concentrations (about 5 nanograms per liter (ng/L) or 5 parts per trillion (ppt)). Geosmin does not pose a public health risk, but its detectible presence in treated drinking water can cause serious public concern about the safety and aesthetic quality of their drinking water. Utilities around the country receive a record number of complaints whenever a geosmin outbreak occurs in their water supply. Geosmin is of special concern to the City, because many of the industrial customers of its water, particularly the several major breweries in Fort Collins, are especially sensitive to any unusual taste or odor properties that customers may detect in their products.

Geosmin has been found in water samples from North Fork reservoirs at concentrations over 100 ng/L (Billica, Loftis, and Moore, 2008). Because of the close proximity and similarities of Glade, Halligan and Seaman Reservoirs, the Corps must analyze whether Glade may have similar geosmin issues and how introduction of geosmin-contaminated water into Horsetooth Reservoir would adversely affect municipal water supplies. It would be of significant concern to the City if blue green algal production in Glade Reservoir resulted in waters with high geosmin concentrations that were then delivered to Horsetooth Reservoir (and ultimately to the City's water treatment facility as part of the City's water supply). This concern relates not only to potential taste and odor issues for the Fort Collins community and major industries but to the significantly higher treatment costs required to remove geosmin back to "non-detect" levels.

Glade or North Fork water containing geosmin must not be delivered to Horsetooth Reservoir. The Corps must evaluate and address the proposed conveyance of Glade Reservoir or North Fork water to Horestooth Reservoir and fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 3.5.2.3 Horsetooth Reservoir, page 3-29
Comment: Section 3.5.2.3 summarizes some of the important water quality issues related to Horsetooth Reservoir. However, TOC was not discussed. Because it is a critical parameter of water quality and chemistry for municipal water supply, it must be assessed in detail by the Corps.

Table 8 (page 33) of the NISP DEIS Water Quality Technical Report (ERO and HDR, March 2008) identifies a 10-year average TOC of 2.9 mg/L in Horsetooth Reservoir. However, this average value does not fully characterize TOC concentrations in Horsetooth Reservoir. Horsetooth Reservoir has experienced a statistically significant upward trend in TOC concentrations over the period of record. This trend has been documented in the Haby and Loftis (2007) report prepared for the Big Thompson Watershed Forum. A plot of TOC data collected at the FCWTF raw Horsetooth sample station and analyzed by the Fort Collins Water Quality Lab is shown on the figure below.



The City is paying close attention to this trend and has initiated a study with researchers at UCLA to better understand the nature and source of TOC in Horsetooth Reservoir. This trend is problematic because, if it continues, the cumulative effect of NISP and the elevated concentrations of TOC in Horsetooth Reservoir will adversely affect Fort Collins' water treatment and the attainment of existing regulated drinking water treatment standards and goals.

The City is paying close attention to this trend and has initiated a study with researchers at UCLA to better understand the nature and source of TOC in Horsetooth Reservoir. This trend is problematic because, if it continues, the cumulative effect of NISP and the elevated concentrations of TOC in Horsetooth Reservoir will adversely affect Fort Collins' water treatment and the attainment of existing regulated drinking water treatment standards and goals. Any increase in Horsetooth Reservoir TOC concentrations that result from the proposed action will exacerbate this situation.

These high TOC levels would produce potential cancer-causing contamination of Fort Collins drinking water. The Corps must evaluate and address the TOC issue and fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 4.5.1 Methods, page 4-33
Statement: *"Changes in the water quality of Horsetooth Reservoir due to deliveries from the Glade-to-Horsetooth or Cactus-to-Horsetooth pipelines were estimated by completing mass balance calculations for Horsetooth Reservoir."*

Comment: The mass balance calculations for the DEIS assume that the inflow is instantaneously and completely mixed with all of the water present within the reservoir. However, the physical and operational characteristics of Horsetooth Reservoir will result in more complex flow and mixing patterns. Horsetooth Reservoir is a very long, relatively narrow, thermally-stratified reservoir that is characterized by three main pools. The Glade-to-Horsetooth pipeline would deliver water to the north end of Horsetooth Reservoir (Section 3.2.6). The City's outlet at Soldier Canyon Dam is also near the north end of Horsetooth Reservoir and provides water to the Fort Collins Water Treatment Facility (FCWTF). Significant short-circuiting could occur with some portion of the flow preferentially going directly from the Glade-to-Horsetooth pipeline to the Soldier Canyon outlet, thereby minimizing the potential for mixing and dilution by the entire volume of Horsetooth Reservoir. In such circumstances, a mass balance model incorrectly underestimates the potential impacts to the water quality at the Soldier Canyon outlet.

The DEIS analysis also does not consider the combined impact on water quality that may occur if smaller quantities of C-BT water are delivered to Horsetooth Reservoir from the Hansen Feeder Canal. Water entering Horsetooth Reservoir from the Hansen Feeder Canal is of higher quality than water from the Glade-to-Horsetooth pipeline, so decreases in Hansen Feeder Canal flows must be accounted for in the analysis since their diluting effect will be reduced. Specific operational plans will need to be developed, evaluated and modeled through a hydrodynamic model that represents the physical and chemical characteristics within the Reservoir to gain insight into mixing issues at the Soldier Canyon pool.

The DEIS Water Quality Technical Report (ERO and HDR, March 2008) indicates that releases to Horsetooth Reservoir from Glade Reservoir will occur during the non-irrigation season (November through March). This would likely lessen the influences that thermal stratification would have on mixing in Horsetooth Reservoir since thermal stratification is most significant in

the summer and early fall seasons. However, depending on actual differences in water temperature between Horsetooth Reservoir water and water in the Glade-to-Horsetooth pipeline, density gradients may still exist that will impact the flow path and distribution of Glade water in Horsetooth Reservoir.

Even without temperature and density differences, short-circuiting, incomplete mixing, and varying flows from both the Hansen Feeder Canal and the Glade-to-Horsetooth pipeline will likely occur. Their influence on water quality at the Soldier Canyon outlet must be evaluated with an appropriate physically-based, numerical model.

Effective drinking water treatment design and operation requires the careful evaluation of worst case scenarios for raw water quality. The mass balance methods used in the DEIS result in annual average values for various water quality parameters and not the extremes of the real world. This level of detail is inadequate to accurately assess potential adverse impacts to water treatment, as required by Sections 230.22 and 230.50 of the Section 404(b)(1) Guidelines. Extrapolating from "average" conditions is not "worse case" and, therefore, not adequate to understand the effects of the proposed projects on drinking water quality. Therefore, the City cannot adequately assess, evaluate or discuss this portion of the DEIS because of this lack of detail. The Corps must provide this analysis in an SDEIS to allow an adequate opportunity for notice and comment on the effects of the project on the City's drinking water supplies.

DEIS Section: 4.5.1 Methods, page 4-33
Statement: *"The water quality of the proposed Glade Reservoir was estimated by Lewis (2003) by completing a mass balance analysis ……"*

Comment: Lewis (2003) estimated the water quality characteristics of the proposed Glade Reservoir using a discharge-weighted average (mass balance) approach for the two sources of water (local watershed runoff and water delivered from the Poudre River) that will enter the Reservoir. Lewis (2003) used only data from year 2000 to calculate the composite quality of the two sources of inflowing water (composite discharge–weighted average concentrations). These values were then used to conduct qualitative projections of water quality in Glade Reservoir based on the expected fate of the key constituents entering the Reservoir.

The use of one year of data is inadequate to make substantive quantitative projections of water quality. In order to gain an adequate understanding of the anticipated range of water quality <u>delivered into</u> Glade Reservoir, this analysis, at the very minimum, must be conducted over a series of several years that include both reservoir filling and emptying cycles. This is particularly important for the evaluation of TOC concentrations, because TOC concentrations tend to be highest in wet years when Glade Reservoir would be filled.

Furthermore, in order to gain a more refined understanding of the quality of water <u>delivered from</u> Glade Reservoir, a monthly mass balance model should be applied over the same series of years (INTERA & CH2MHill, 2006b). Such a model should consider reservoir storage volumes, reservoir inflow and outflow volumes, and concentrations of key constituents (TOC) in the inflow, outflow, and within the stored volume, all on a monthly basis. If reservoir operations are well defined, this would result in a better, more refined understanding of the potential quality of

water delivered from Glade. However, as stated previously, mass balance calculations assume complete and instant mixing of influent water with water already in the Reservoir. That assumption is not correct in the real world of reservoir dynamics. In order to accurately evaluate the effects of flow dynamics on the quality of water delivered from Glade (in particular, TOC concentrations), a physically based, numerical model must be used.

This information is highly important to an assessment of the effect of the project on municipal drinking water supplies and must be included for public review and comment in an SDEIS and Revised 404(b)(1) Analysis for this project to meet the requirements of Section 404(b)(1) and NEPA.

DEIS Section: 4.5.5 Horsetooth Reservoir, page 4-35
Statement: *"Under Alternative 2, it is estimated that the average annual volume that would be pumped through the Glade-to-Horsetooth pipeline would be 2,600 acre feet, with a maximum annual volume of about 7,000 acre-feet. … Given that the average inflow would be about 2 percent of the average total storage volume during delivery, or about 6 percent during maximum delivery, and that the expected Glade Reservoir nutrient, dissolved solids, total organic carbon and chlorophyll concentrations are lower or only slightly higher than Horsetooth concentrations, it is expected that the water quality of Horsetooth Reservoir would not be negatively affected by inflows from Glade Reservoir."*

Comment: Horsetooth Reservoir is one of two source waters for the City's Fort Collins Water Treatment Facility (FCWTF). It is essential to the City that the existing high quality of its source waters be maintained in order to avoid increased treatment costs, assure overall system reliability, and to provide the highest quality water to its customers. Because of the higher Total Organic Carbon (TOC) associated with Poudre River Basin water and the proposed Glade-Horsetooth Pipeline delivery point near the FCWTF intake, discussed above, deliveries to Horsetooth Reservoir from the Glade-to-Horsetooth pipeline are likely to degrade water quality at the FCWTF intake at Soldier Canyon Dam. The Section 404(b)(1) Guidelines Section 230.50 (Municipal and private water supplies) require that impacts to the quality of drinking water supplies be fully evaluated for NISP. Increases in concentrations or changes in seasonal occurrences of TOC or other water quality parameters at the FCWTF Horsetooth Reservoir intake will impact treatment strategies, process performance, and treatment costs.

The analysis conducted for the DEIS on the potential water quality impacts of the delivery of Glade Reservoir water to Horsetooth Reservoir is inadequate for reasons as stated in comments for Sections 4.5.1. Inadequacies are present in the evaluation of TOC concentrations in waters entering Glade Reservoir, TOC concentrations in waters leaving Glade Reservoir, the flow path and extent of mixing of this water once it reaches Horsetooth Reservoir, and the changes in TOC concentration that will ultimately be observed at the Soldier Canyon Dam outlet. Although TOC is considered the parameter of most concern, these inadequacies would also apply to the analysis of other parameters of concern (including pathogens such as *Giardia* and *Cryptosporidium*, manganese, and geosmin). The conclusion stated in the DEIS that Horsetooth Reservoir would not be negatively affected by inflows from Glade Reservoir is, therefore, untenable until it is supported by a more thorough and rigorous analysis.

The statement "*… it is estimated that the average annual volume that would be pumped through the Glade-to-Horsetooth pipeline would be 2,600 acre feet with a maximum annual volume of about 7,000 acre-feet"* is not supported by an adequate description of the proposed deliveries. Further documentation is needed to show how these delivery volumes were calculated and the underlying assumptions behind them. This description must cover a range of specific delivery scenarios, including the worst-case scenario. For example, it is not clear whether these estimated deliveries were based on the amount of Colorado-Big Thompson (C-BT) water available to perform Glade exchanges or other factors. This description must fully assess not just the current, but the future C-BT ownership levels and municipal leasebacks in the Poudre River Basin, with particular emphasis on the projected reduction of agriculturally owned C-BT units in the Poudre River Basin (2008 NCWCD April Water Delivery Report).

The District's April 2008 Water Delivery Report also shows that just fewer than 60,000 C-BT units are owned by entities that have C-BT water delivered to the Poudre River. Of this, about 28,000 units are owned by municipalities through ownership of North Poudre Irrigation Company shares. This results in about 32,000 owned units available for delivery of water to the Poudre River. Based on annual delivery quotas from 50% to 100%, this translates into a range of 16,000 acre feet to 32,000 acre feet available for potential exchanges on the Poudre River. In addition to this, there may be a limited amount of municipally owned C-BT water available for rental to agricultural users and delivered to the Poudre River. There has been, however, a clear history of C-BT units being transferred from agricultural owners to municipal owners with less C-BT water becoming available for agricultural use. *See e.g.*, NCWCD, *NISP Phase II Alternative Evaluation* at ES-5 (Jan. 2004) (showing reduction in agricultural C-BT units by over 50% after 2020). Considering these factors, there will not be adequate C-BT water available in the Poudre River Basin to accomplish the exchange referred to in DEIS Section 2.3.3.1 to meet the 29,500 acre feet of demand by the NISP Southern Participants. Further analysis in an SDEIS is required to determine the exchange potential available on the River in the future. As this exchange potential decreases, the amount of NISP water that needs to be transferred directly from Glade facilities to either Carter Lake or Horsetooth Reservoir will increase. The potential Glade-to-Horsetooth pipeline delivery values may be significantly underestimated and more flow through this pipeline could further degrade water quality in Horsetooth Reservoir.

The statement "*Given that the average inflow would be about 2 percent of the average total storage volume during delivery, or about 6 percent during maximum delivery,..*" emphasizes the fact that the DEIS analysis assumed that Glade water delivered to Horsetooth Reservoir will be completely mixed with the entire volume of water stored in Horsetooth Reservoir. This analysis underestimates the impact to Horsetooth water quality at the Soldier Canyon outlet, because short-circuiting and incomplete mixing will likely occur. This analysis also does not consider the combined impact on water quality that may occur if changes are made in the amount of water delivered to Horsetooth Reservoir from the Hansen Feeder Canal. If flows from the Hansen Feeder Canal are decreased, the diluting effects of this water will be diminished.

The statement "*... and that the expected Glade Reservoir nutrient, dissolved solids, total organic carbon and chlorophyll concentrations are lower or only slightly higher than Horsetooth concentrations,*" is inaccurate with respect to TOC. The Horsetooth Reservoir TOC

concentration (as measured at the FCWTF) is about 3 mg/L. A long-term average TOC concentration of 2.9 mg/L for Horsetooth Reservoir is shown in Table 8 (pg 33) of the NISP Water Quality Technical Report (ERO and HDR, March 2008).

In comparison, a long-term equilibrium mean TOC concentration of 4.5 mg/L has been predicted by the Corps' consultants for Glade Reservoir water (ERO and HDR, March 2008, Table 16, pg 49). However, more detailed analysis conducted by INTERA and CH2MHill (2006b) for the City of Fort Collins Utilities indicated that Poudre River water diverted into Glade Reservoir will have annual average TOC concentrations ranging between 4 and 7 mg/L, with a long-term annual average of about 5.5 mg/L. The analysis conducted by INTERA and CH2MHill (2006b) also estimated that the monthly average TOC concentration for water delivered from Glade Reservoir would be above 5 mg/L most of the time and could be as high as 9 mg/L depending on the specific operation plans. Although the operational plans used in the analyses by INTERA and CH2MHill (2006b) were not the final operational plans (since those have not been provided or described by the Corps or the District), they are consistent with what was available for the Lewis (2003) analysis.

A Glade Reservoir TOC greater than 5 mg/L (with monthly average values that can exceed 9 mg/L) is significantly higher than a Horsetooth Reservoir TOC of 2.9 mg/L.

The above analysis is based on one key assumption - that future conditions will be within the range of historic flows and TOC concentrations. However, as is discussed below in Section IV.6 of these Comments, climate change impacts are likely to result in more extreme hydrologic conditions, which are known to be associated with poorer water quality conditions, including elevated TOC concentrations in the Poudre River. Even if accurate quantitative predictions are not available at this time, synthetic flow records with associated water quality parameters should be used to evaluate the possible future range of expected water quality conditions in any proposed reservoir.

The FCWTF water supply from Horsetooth Reservoir historically represents a lower concentration of TOC that can be used to supplement the Poudre River supply during the spring runoff when treatability is impaired by high TOC. Other water quality parameters of concern (including pathogens such as *Giardia* and *Cryptosporidium*, taste and odor compounds such as geosmin, turbidity, and dissolved manganese) are also generally present at seasonally high concentrations in one source water and not the other. Hence, a tactical treatment strategy practiced at the FCWTF is to adjust the raw water blend to increase the amount of water from the higher quality source. This operational flexibility is critical both for ensuring regulatory compliance and for meeting the water quality standards established by the City in order to meet the expectations of Fort Collins water customers and major industries in Fort Collins. If the Glade-to-Horsetooth pipeline were constructed, the water quality in Horsetooth Reservoir would be degraded, and this operational flexibility would be severely compromised and resulting water treatment costs for Fort Collins water customers would escalate.

Section 4.5.5 fails to discuss potential contamination of Glade with geosmin. That compound has been found in water samples from North Fork reservoirs at concentrations over 100 ng/L (Billica, Loftis, and Moore, 2008). Those levels are more than ten-times the offensive odor

threshold of the average person. Because of the close proximity and similarities of Glade, Halligan and Seaman Reservoirs, the Corps must analyze whether Glade may have similar geosmin issues and how introduction of geosmin-contaminated water into Horsetooth Reservoir would adversely affect municipal water supplies. It would be of significant concern to the City if blue green algal production in Glade Reservoir resulted in waters with high geosmin concentrations that were then delivered to Horsetooth Reservoir (and ultimately to the City's water treatment facility as part of their water supply). This concern relates not only to potential taste and odor issues for the Fort Collins community and major industries but to the significantly higher additional treatment costs required to remove geosmin back to "non-detect" odor threshold levels.

Glade or North Fork water containing geosmin must not be delivered to Horsetooth Reservoir. The Corps must evaluate and address the geosmin issue and fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

The FCWTF is a conventional treatment plant. The FCWTF and its improvements over the years were designed to provide removal of TOC, pathogens, turbidity, manganese, and geosmin at concentrations that have historically been present at the existing diversion/intake structures. The most recent major upgrade to the FCWTF was completed in 2000 at a cost of $22.7 million. If the water quality in Horsetooth Reservoir is degraded, annual treatment costs will increase and advanced treatment processes, with associated capital and annual operation and maintenance (O&M) costs, may be required.

An analysis of costs associated with treating Horsetooth Reservoir water that has been degraded as a result of the Glade-to-Horsetooth pipeline was conducted by CH2MHill (2006). The opinion of probable cost was made based on assumptions about operational scenarios and the quality of water in Glade Reservoir. Although these cost estimates will require refinement after more thorough and rigorous modeling of Glade and Horsetooth Reservoirs has been conducted, they provide insight into the significant potential adverse economic impacts to water treatment at the FCWTF.

TOC removal and disinfection byproducts (DBP) formation during water treatment are complex processes. Both depend on the nature, composition, structure, and reactivity of the various organic compounds that make up the TOC as well as the alkalinity, temperature and other chemical-physical characteristics of the raw water. The conventional treatment processes currently present at the FCWTF can remove TOC (at current concentration ranges and characteristics) to meet the City's regulatory requirements, adopted treatment goals, and customer expectations for both TOC removal and DPB levels. If the City's conventional treatment processes can remove the increased TOC levels due to NISP, the added operational costs to the City due to NISP will be to pay the costs of higher chemical doses (alum and lime) plus the higher cost for increased solids handling due to the corresponding higher level of solids production. For this case, CH2MHill (2006) estimated that the additional annual operating costs associated with treating water with higher TOC concentrations is approximately $40,000 (annual additional alum, lime, and solids handling costs). Note that this value is in 2006 dollars and alum costs have increased by 33% in 2008 alone. Fuel costs have also increased significantly in

2008 which, in turn, also adversely impact chemical delivery and solids handling costs. Thus, actual costs will almost certainly be higher. Unfortunately, the precise costs are uncertain because there is not sufficient operational data or modeling information provided in the DEIS to evaluate the ultimate impacts of NISP on TOC levels delivered to the FCWTF.

It must be emphasized that the FCWTF was designed to operate within the constraint of existing raw water quality conditions observed in both Horsetooth Reservoir and the Cache la Poudre River. However there is not sufficient operational data provided in the DEIS or accompanying technical reports to determine just how high the long-term transport of high TOC water from Glade Reservoir to Horsetooth would increase TOC levels in Horsetooth beyond current plant design and operational constraints.

Should higher TOC concentrations in Horsetooth Reservoir due to NISP (or major changes in the Poudre watershed like catastrophic fires) reach levels where the City's existing conventional treatment processes would not meet existing or future Federal and State Safe Drinking Water regulatory requirements for both TOC removal and reduced DBP Maximum Contaminant Levels (MCLs), then an advanced treatment process such as granular activated carbon (GAC) filtration will need to be designed, constructed, operated and maintained to remove the DBP precursors -- TOC. GAC filtration is one method of effectively removing the TOC precursors that form DBPs. The cost estimate for a GAC system at the FCWTF (including GAC contactors and associated pump stations) includes a capital cost of $56.3 million and an annual O&M cost of $1.9 million, both in 2006 dollars (CH2MHill, 2006). However, as noted above, the DEIS does not provide sufficient operational data or modeling information provided in the DEIS to establish this likelihood

Cost estimates were also developed by CH2MHill (2006) for ultra-violet (UV) disinfection and ozone/advanced oxidation if the required additional modeling and monitoring indicate that other potential water quality issues (potential MCL violations, pathogens, geosmin, and algal toxins) must also be addressed by the FCWTF as a result of the Glade-to-Horsetooth pipeline. Capital costs for a UV disinfection system were estimated at $12.9 million with an annual O&M cost estimate of $ 448,000. Capital costs for an ozone/advanced oxidation system were estimated at $20.8 million with an annual O&M cost estimate of $544,000 (all costs expressed in 2006 dollars). In summary, advanced treatment capital costs could exceed $90 million with additional annual O&M costs of nearly $3 million). And once again there is there is not sufficient operational data or modeling information provided in the DEIS to evaluate the likelihood of these expenses.

The Corps must evaluate and address the cumulative adverse impacts associated with high TOC water and related water treatment impacts and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. *See also* Summary of TOC-Related Impacts to Fort Collins Drinking Water Quality in Section III.1c, below.

DEIS Section: 4.5.6 Glade Reservoir, page 4-35

Statement: *"No specific water quality problems are anticipated for the reservoir with the possible exception of manganese release under low dissolved oxygen conditions."*

Comment: As discussed in comments for Section 4.5.1 and Section 4.5.5, the TOC concentrations in Glade Reservoir are expected to be above 5 mg/L most of the time. Concentrations above 5 mg/L are high compared to the average TOC concentration in Horsetooth Reservoir of 2.9 mg/L. In addition, considering the geosmin concentrations that have been measured in nearby North Fork Poudre River reservoirs (as discussed in comments for Section 3.5.2.1), there is concern that geosmin concentrations could also be elevated in Glade Reservoir. Therefore, the existing analysis does not support the DEIS's statement regarding the effect of the project on water quality in Horsetooth. Additional analysis is needed in an SDEIS to fully and adequately assess the effects of the proposed project on TOC and geosmin levels.

Because of the cumulative adverse impacts associated with treating high TOC water or geosmin-contaminated water, Glade water should not be delivered to Horsetooth Reservoir. The Corps must evaluate and address the cumulative adverse impacts associated with high TOC water or geosmin-contaminated water, and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 4.28.2.1 Water-Based Actions, page 4-104
Statement: *"Although climatic change is considered reasonably foreseeable, there is no accepted science for transforming the general concept of variations in global temperature into incremental changes in streamflow at particular locations. Hydrologic changes attributable to global climate change are a possibility; however, potential impacts have not been quantitatively estimated in the EIS because of the uncertainties associated with predicting change and the effects."*

And;

DEIS Executive Summary, page ES-14
Statement: *"Climate change may affect precipitation, Poudre River streamflows, and the amount of water available for diversion by NISP, which could alter how the action alternatives operate and, in combination with the action alternatives, could further alter flows in the Poudre River."*

Comment: While accurate quantitative analysis of climate change impacts on the Poudre River has not been undertaken in the DEIS, it is widely accepted that one of these impacts will be a wider range of fluctuations between wet and dry years. That is, more extreme dry and wet years are more likely in the future. Refer to AWWA (2006), among many other studies. While the assessment of these impacts on the available water supplies is beyond the scope of this comment, it must be stated that within the Poudre River system, wetter-than-average years are typically characterized by poor water quality, especially when they are preceded by dry years. For example, the two years with the highest recorded annual average TOC at the Bellvue gauge (USGS 06752000) are 1995 and 1983. Both years are preceded by 2 or 3 years of dry weather

(1981, 1982, 1992, 1993, and 1994). This suggests that TOC levels are likely to go higher in the future for most of the years in which NISP water is delivered to Glade (or Cactus Hill) Reservoir. This means that TOC estimates based on the historic records will likely be inaccurate by significantly underestimating the actual levels in either proposed reservoir.

DEIS Section: 5.8.1 Total Organic Carbon, page 5-16
Statement: *"If TOC is not regulated by the Colorado water quality program, then 5 years prior to constructing the Glade-to-Horsetooth pipeline, the District will develop a plan for monitoring TOC in Horsetooth and Glade Reservoirs. This plan will be submitted to the Corps and Reclamation for their review and approval."*

Comment: The only way to address the impacts of the proposed project on the municipal drinking water supplies of the City is to avoid placing Glade water into Horsetooth Reservoir or the Pleasant Valley Pipeline (PVP). However, if the NISP water may be conveyed to Horsetooth or in the PVP, water quality monitoring will be essential for further evaluation of the potential impact of the Glade-to-Horsetooth pipeline on the quality of water in Horsetooth Reservoir. Any monitoring plan must provide for the evaluation of TOC concentrations as well as detailed TOC characteristics. Knowledge of TOC characteristics is important because TOC removal and DBP formation both depend on the nature, composition, structure, and reactivity of the various organic compounds that make up the TOC in the raw water.

Further, if the Corps does not fulfill its duty to avoid or minimize these impacts, it is essential that the Corps develop and evaluate a mitigation plan in an SDEIS and include it as a condition in any permit. As discussed above at the DEIS Section 4.5.5 comments, it is very unlikely that adequate Colorado-Big Thompson (C-BT) exchange units will be available in the future to meet participant demand for NISP water by Poudre River exchanges alone. Further, the District's April 24, 2008, Application for Department of the Army Permit includes the Glade to Horsetooth Pipeline as part of the project to be permitted. Thus, the effects of the proposed pipeline must be evaluated and addressed as part of the review of NISP under NEPA and Section 404. The Corps must evaluate and fully address the impacts associated with conveyance of Glade water to Horsetooth or via the PVP in an SDEIS in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

Statement: *"If monitoring indicates that the delivery of water from Glade Reservoir to Horsetooth Reservoir will increase the levels of TOC in Horsetooth Reservoir to levels determined by Reclamation to be unacceptable ……."*

Comment: The Corps cannot legally defer its analysis, avoidance, minimization and mitigation of any impacts to municipal drinking water supplies to the Bureau of Reclamation or to a future time, as discussed above in Section II.7. The District has included the Glade-Horsetooth Pipeline in its application and the facts indicate that some physical connection between Glade and Horsetooth Reservoir, Carter Lake or one of the pipelines will be necessary. Thus, the Corps must fully assess the potential impacts of such a reasonably foreseeable connection in an SDEIS and ensure that it complies with its obligation to fully address those impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. The Bureau of Reclamation cannot make these findings in the

future. At a future date, the project will have been built and the alternatives to a Glade-Horsetooth pipeline will be diminished or unavailable. Leaving analysis of the pipeline to later constitutes impermissible segmentation under NEPA Existing TOC, geosmin and other pollutant levels in Horsetooth serve as the standard that must not be degraded. *See* Section II.7 of these Comments.

While water quality monitoring would be very important if a connection to Horsetooth Reservoir were allowed, the Corps must do more now to fully assess the impacts to municipal drinking water supplies. In order to fully understand the potential impacts to TOC concentrations at the Soldier Canyon outlet, more rigorous mathematical modeling must be conducted in an SDEIS to account for the specific operational and physical characteristics of Horsetooth Reservoir and to provide for the evaluation of the significance of short-circuiting and mixing on water quality. Effective drinking water treatment design and operation requires the evaluation of worse case scenarios for raw water quality. This requires mathematical modeling that is more rigorous than that presented in the DEIS.

The Bureau of Reclamation has no track record in providing municipal water treatment services, complying with safe drinking water regulations, or the specific needs of Fort Collins water customers such as brewers or chip manufacturers. The City should be included as an active participant in the process of setting the criteria for "acceptability" and "unacceptability".

Statement: *"……the District will develop a TOC mitigation plan for review and approval by the Corps and Reclamation."*

Comment: As noted above, the Corps cannot defer its analysis of the effects of the project on municipal water supplies or its consideration of avoidance, minimization and mitigation. Since neither the District nor the Bureau of Reclamation has any experience or track record in providing municipal water treatment services or complying with safe drinking water regulations, the City must be included as an active participant in the development, design, review, and approval of any Total Organic Carbon (TOC) mitigation plan. TOC mitigation measures that must be considered include: 1) NISP without the Glade-to-Horsetooth pipeline, 2) locating the pipeline such that it delivers water to the south end of Horsetooth Reservoir instead of the north end, 3) implementation of operational scenarios that minimize the delivery of the highest TOC water to Horsetooth Reservoir, 4) structural provisions for the option to selectively divert lower TOC Poudre River water directly from the Glade Reservoir forebay to Horsetooth Reservoir, and 5) compensation to the City for increased water treatment costs.

In order to evaluate and fully address the TOC issue and related impacts in accordance with Section 404(b)(1) will require detailed analysis and mathematical modeling that has not been attempted in the DEIS and must be described and presented for public comment in an SDEIS. All appropriate steps must be implemented to protect the City's municipal drinking water supplies. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section: 5.8.2 Manganese and Nutrients, page 5-16
Statement: *"To prevent adverse impacts to the water quality of Horsetooth Reservoir due to delivery of water from either Glade or Cactus Hill reservoir, Glade or Cactus Hill reservoir could be operated to avoid manganese or nutrient releases from the lake bottom or by avoiding the release of deeper waters when the lake is drawn down by using a multiple outlet withdrawal structure."*

Comment: A water quality monitoring program must be designed and implemented for Glade Reservoir when reservoir filling commences. However, it will take a number of years of water quality data collection to fully determine the magnitude and extent of water quality issues in Glade Reservoir. The design and construction of Glade Reservoir must anticipate water quality issues and provide for their probable occurrence with appropriate water management strategies. A multi-level outlet structure should be installed for any proposed reservoir. Combined with an active water quality monitoring program, this design will allow significantly better management of the reservoir for water supply operations.

The Corps must evaluate the issue of water quality in Glade, and particularly the manganese and nutrient levels in Glade and must fully address the expected impacts from this issue in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. The City should be included as an active participant in the development, design, and approval of any water quality monitoring plans and in the definition of unacceptable water quality parameter/contaminant levels.

1b. Comments on Supplemental Information

Department of the Army, Corps of Engineers (Corps), Omaha District letter of 11 July 2008 from Chandler Peter in response to the 04 June 2007 letter from Ms. Lori Potter of Kaplan Kirsch & Rockwell, LLP. "Re: Second Request for Additional Information – Northern Integrated Supply Project Draft Environmental Impact Statement"
Statement: "**Bullet 3: Request for background calculations on TOC for Cactus Hill Reservoir.** *For Total Organic Carbon, there were 15 measurements at the Poudre Canyon Mouth site collected in April through July in 1993, 1994 and 1995.* ***The median value is 0.4 mg/L and the mean value is 0.7 mg/L.*** **[emphasis added]** *For Lonetree Creek, there are 27 measurements with a median value of 3.1 mg/L and a mean value of 3.5 mg/L. Using the median values, the weighted concentration for TOC would be 0.45 mg/L and using the mean values, the weighted concentration would be 0.75 mg/L."*

Comment: As shown below, the incorrect chemical-physical form of USGS Total Organic Carbon (TOC) was selected from the USGS database and used to develop the results presented in Table 5, page 24 of the Water Quality Technical Report (WQTR). The data in Table 5 of the WQTR states that the range of TOC values for Poudre River water at the mouth of the canyon (USGS Site 06752000) was 0.1 to 2.1 mg/L with a mean value of 0.44 mg/L. **Those results are for "Organic Carbon, suspended sediment" and not the "Organic carbon, water, filtered" form given in the USGS database.** Measured on samples taken at USGS site 06752000 from the Poudre at the mouth of the canyon, the **range of observed TOC values was in reality from**

2.1 to 8.4 mg/L with a median value of 3.8 mg/L and a mean value of 4.6 mg/L and not the incorrect low values presented in Table 5, page 24 of the WQTR or in Bullet 3 of the 11 July 2008 Corps letter.

The correct data and methods descriptions taken from the USGS Web Site are as follows:

USGS Measured forms of TOC April through July 1993, 1994, and 1995:
1. USGS 06752000: 1972-05-18 to 2002-08-07 Poudre River at Mouth of Canyon, **Organic carbon, water, filtered, milligrams per liter, parameter code "p00681"**

2. USGS 06752000: 1993-04-06 to 1995-08-10 Poudre River at Mouth of Canyon, **Organic carbon, suspended sediment, total, milligrams per liter, parameter code "p00689"**

Data table derived from the USGS Web Site for site 06752000 with all samples collected and tested by the USGS:

USGS 06752000, Poudre at Mouth of Canyon	**Organic carbon, water, filtered, milligrams per liter**	**Organic carbon, suspended sediment, total, milligrams per liter**
Date	**Test Code p00681**	**Test Code p00689**
4/6/1993	2.9	0.7
5/4/1993	4.5	0.4
6/10/1993	6.0	0.5
6/18/1993	8.1	1.8
7/8/1993	3.6	0.3
4/20/1994	2.1	0.3
5/3/1994	3.7	0.3
6/7/1994	4.2	0.3
6/14/1994	3.4	0.2
7/6/1994	2.4	0.4
4/10/1995	2.2	0.3
5/11/1995	3.8	1.4
6/13/1995	8.4	2.1
6/20/1995	7.8	0.9
6/30/1995	6.3	0.6

Descriptive Statistics on the TOC Data Table (above) for USGS Site 06752000, Poudre River at mouth of canyon:

Column	Size	Missing	Mean	Std Dev	Std. Error	C.I. of Mean
p00681	15	0	**4.627**	2.164	0.559	1.198
p00689	15	0	**0.700**	0.596	0.154	0.330

1c. Summary of TOC-Related Impacts to Fort Collins Drinking Water Quality

[REMAINDER OF PAGE INTENTIONALLY LEFT BLANK]

Summary of TOC -Related Impacts of NISP Operations on City of Fort Collins Drinking Water Quality

Water Quality Parameter	Regulatory Requirement or MCL	Current Regulatory Compliance Status	Impact of NISP	Adversely Affected Waterbody
Total Organic Carbon (TOC) removal requirement	Must meet independent, monthly- adjusted, alkalinity-dependent percent removal requirement.	Currently in compliance; City is able to use low TOC Horsetooth water during high TOC Poudre spring runoff.	(1) Strong probability that high TOC Poudre water pumped to Glade & then transferred to Horsetooth will degrade City's source water supply (2) NISP use of CBT water by exchange can be expected independently to lower water quality in Horsetooth due to less opportunity for dilution.	Horsetooth Reservoir raw water supply
Disinfection By-Products (DBPs): Total Trihalomethanes (TTHMs) Maximum Contaminant Level	0.080 mg/L or parts per million	Currently in compliance; City is able to use low TOC Horsetooth water during high TOC Poudre spring runoff.	(1) Strong probability that high TOC Poudre water pumped to Glade & then transferred to Horsetooth will degrade City's source water supply (2) NISP use of CBT water by exchange can be expected independently to lower water quality in Horsetooth due to less opportunity for dilution.	Horsetooth Reservoir raw water supply

Summary of TOC-Related Impacts of NISP Operations on City of Fort Collins Drinking Water Quality (*continued*)

Water Quality Parameter	MCL or Regulatory Requirement	Current Regulatory Compliance Status	Impact of NISP	Adversely Affected Waterbody
DBPs: Total Halo-Acetic Acids (HAA5) Maximum Contaminant Level	0.060 mg/L or parts per million	Currently in compliance; City is able to use low TOC Horsetooth water during high TOC Poudre spring runoff.	(1) Strong probability that high TOC Poudre water pumped to Glade & then transferred to Horsetooth will degrade City's source water supply (2) NISP use of CBT water by exchange can be expected independently to lower water quality in Horsetooth due to less opportunity for dilution.	Horsetooth Reservoir raw water supply
DBPs: Chlorite Maximum Contaminant Level	1 mg/L monthly average	Currently in compliance; chlorite is a byproduct of the chlorine dioxide used for manganese removal; current doses of chlorine dioxide result in chorite levels below the MCL.	NISP may result in increased levels of dissolved manganese at the City's Horsetooth intake that would result in the need for a higher chlorine dioxide dose. In order to stay below the chlorite MCL, the City may have to install and operate additional chemical feed systems to add other oxidants for effective manganese removal.	Horsetooth Reservoir raw water supply

2. Water Quality Impacts on the Poudre River Due to Deliveries from the NISP project

2a. Comments on DEIS

DEIS Section: 3.23 Hazardous Sites, page 3-124
Statement: *"A review of the Colorado Department of Public Health and Environment (CDPHE) database indicates that several hazardous materials sites are known in the region (Table 3-33 and Figure 3-20)."*

Comment: Table 3-33, and Figure 3-20 do not include three potential hazardous materials sites in the Glade Reservoir inundation area. These include:

1) The Forks Lumber Company located at 7800 US Highway 287 in Laporte, CO 80535. Pentachlorophenol or other hazardous wood preservatives may have been used at this site,
2) The Larimer County Sheriff's pistol range located north of the Forks Lumber Co. The pistol range site is expected to contain heavy concentrations of lead from spent ammunition.
3) The Highway 287 right-of-way is expected to contain unknown but potentially heavy concentrations of oil, gas, antifreeze and other hazardous vehicle fluids.

These hazardous materials sites and their potential impacts on water quality in Glade Reservoir must be thoroughly evaluated in an SDEIS and effective steps taken to avoid, minimize the harm, or otherwise effectively mitigate the potential health risks or environmental damage from these sites.

DEIS Section: 4.5.9 Surface Water Quality Mitigation
Statement (Page 4-36): *"To mitigate water quality effects that may occur from Fort Collins to the mouth of the Poudre River, advance wastewater treatment may be required to meet effluent limits at lower flows and warmer stream temperatures."*

And;

Statement (Page 3-25): *"The Cache la Poudre River from Boxelder Creek to the South Platte River is on the 2006 303(d) list for selenium and E. coli."*

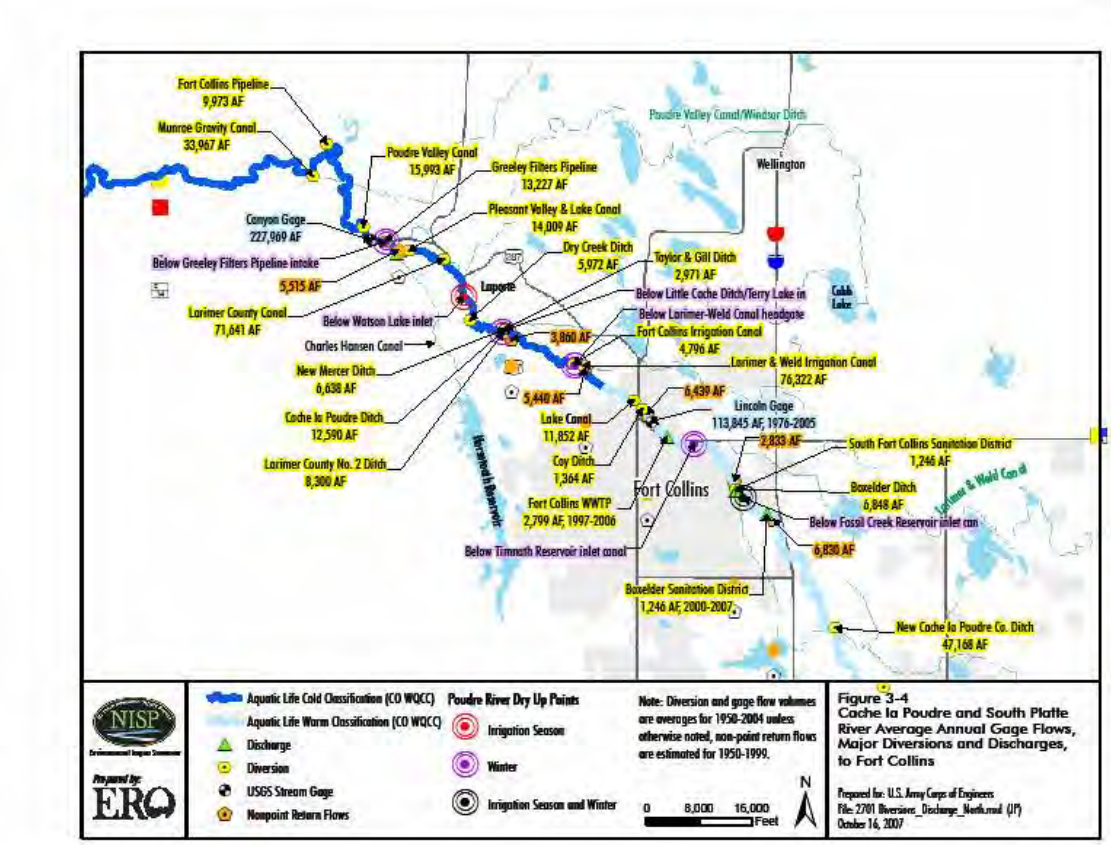
Comment: Bacterial pathogens in river water can cause a variety of intestinal infections including dysentery, hepatitis, typhoid fever, and cholera. Water-borne pathogens are difficult to quickly recover and identify in the laboratory. However, *E. coli* is abundant in human and animal fecal material and relatively easy to cultivate. Hence, detecting the presence of *E. coli* in water is the traditional key indicator of fecal contamination and possible presence of water-borne human pathogens (EPA 1978, Geldrich 1990).

The Poudre River is already listed as impaired under Section 303(d) for violations of the *E. coli* stream standard downstream of Boxelder Creek. Boxelder Creek at the Poudre River is located just below the City's Natural Areas south of Prospect Road. Decreased river flows from NISP operations will further aggravate this impairment since there will be less dilution water for all potential pollutants in the River including water-borne human pathogens. Consequently, lack of sufficient dilution water will further degrade the human-health safety and aesthetic quality of the Poudre River through Fort Collins. Reduced river flows will likely result in higher concentrations of *E. coli* and pathogens downstream of the City's stormwater discharges as well as the City's two water reclamation facilities. If *E. coli* populations surpass the State of Colorado's standards for natural swimming areas, the Poudre River within the City limits may need to be posted as a "no body contact" and "no swimming" zone.

Furthermore, the Poudre River upstream of Boxelder Creek, essentially in the heart of the City, may also become 303(d)-listed as threatened and impaired for *E. coli* contamination. This would seriously impair water-based recreation and the use of parks within the City.

The DEIS states that the City may be forced to implement advanced wastewater treatment (AWT), but does not analyze the obligation of the Corps to fully evaluate and address the issue of elevated concentrations of *E. coli* and associated water-borne pathogens due to reduced river flows through Fort Collins, and the related impacts, pursuant to the Section 404(b)(1) Guidelines. The Corps must consider the known health risks associated with elevated *E. coli* counts in water, and the potential for reduced river flows from NISP to result in higher *E. coli* levels. The City should be included as an active participant in the development, approval, and implementation of any monitoring program. At a minimum, the project proponents should bear all costs associated with monitoring, reporting, and removing elevated populations of water-borne *E. coli* and associated pathogens in the Poudre River through the City due to reduced river flows.

DEIS Figure: 3-14, page 149
Statement: *"Cache la Poudre and South Platte River Average Annual Gage Flows, Major Diversions and Discharges, to Fort Collins...."*



Comment: The diagrammatic representation of "... Major Diversions & Discharges ..." in Figure 3-4 is not correct. The diagram depicts Boxelder Sanitation District (BSD) discharging to the Poudre River below South Fort Collins Sanitation District (SFCSD); this is not correct. The BSD discharges to the Poudre River just below Boxelder Creek. The diagram shows the SFCSD discharging to the Poudre River in the vicinity of east Prospect Street in Fort Collins; this is not correct. The SFCSD discharges directly into Fossil Creek Reservoir.

There is also no depiction of the City of Fort Collins Drake Water Reclamation Facility (DWRF) in Figure 3-4. Furthermore, there is no indication in the diagram of where the average of 10 million gallons of treated effluent is being discharged every day. The DWRF, rated at 23 million gallons per day (mgd), has three permitted discharge points: to the Rawhide Power Plant, to Fossil Creek Reservoir Inlet Ditch, and to the Poudre River. All of the DWRF discharge points are located upstream of the BSD discharge point. In addition, the depiction of Fossil Creek Reservoir at the bottom of the diagram does not show the true location of the SFCSD at the west end of the Reservoir.

Both the Water Quality Technical Report (WQTR) and the DEIS Figure 3-4 proceed in their presentations, analyses and discussions as if the SFCSD discharges are above the BSD and, furthermore, that the City of Fort Collins' DWRF does not exist. These errors and omissions cast serious doubt on the accuracy of both flow and water quality-related information presented not only in Figure 3-4 but throughout both the WQTR and the DEIS regarding the Poudre River

in the Fort Collins area. Potential adverse impacts of NISP on the Poudre River through Fort Collins cannot be adequately evaluated because of incorrect locations of the water reclamation facilities in the area and incorrect information regarding both specific treated wastewater discharge points and discharge volumes. These are fundamental errors and omissions, and the analyses must be corrected and presented for public review in an SDEIS to allow the public a reasonable opportunity to comment on the impacts of NISP at and below these facilities.

DEIS Section: 3.5.1 Water Quality Standards, page 3-24
Statement: *"The Cache la Poudre River from Boxelder Creek to the South Platte River is on the 2006 303(d) list for selenium and E. coli. Horsetooth Reservoir is on the 2006 303(d) list for dissolved oxygen. The Cache la Poudre River from the confluence with the North Fork of the Cache la Poudre River to Shields Street is on the M&E list for aquatic life use."*

Comment: The Colorado Water Quality Control Commission (WQCC) adopted the 2008 303(d) list on March 11, 2008. Section 303(d) of the Clean Water Act requires States to identify waters that do not or are not expected to meet applicable water quality standards with technology-based controls alone. The Poudre River from the Monroe Canal to Shields Street is on the 2008 303(d) list for pH and copper**.** The Poudre River from Boxelder to the South Platte River remains on the 2008 303(d) list for selenium and E. coli. The Poudre River from the confluence with the North Fork of the Poudre River to Shields Street remains on the M&E list for aquatic life use. Horsetooth Reservoir is on the 2008 303(d) list for dissolved oxygen and aquatic life use (5 CCR 1002-93). It is important for an SDEIS and subsequent documents to note the 2008 303(d) listings on the Poudre River and Horsetooth Reservoir as these water-bodies are already not expected to meet applicable water quality standards. The action alternatives listed in the DEIS will contribute to and exacerbate non-attainment of water quality standards by reducing dilution flows, increasing water temperature and pH, decreasing dissolved oxygen, and degrading overall water quality (see water quality section of DEIS and the Water Quality Technical Report). *See* Section 404(b)(1) Guidelines Section 230.22 (water).

The DEIS's analysis of these issues is inadequate. The Corps must evaluate and address the adverse water quality impacts from the substantial reductions in flow from NISP and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

DEIS Section: 3.5.2 Potentially Affected Environment, page 3-26 and 3-27; and Water Quality Technical Report (WQTR) Table 1, page 18 and Table 2, page 19
Statement: *"The water quality standard for temperature is listed in Table 3-9 as 30ºC and in Table 3-10 as 20ºC. The same temperature standard information is repeated in Tables 1 and 2 of the WQTR."*

Comment: The water quality standards for temperature listed in Table 3-9 and Table 3-10 of the DEIS and Tables 1 and 2 of the WQTR does not recognize the adoption of new temperature criteria in January 2007, by the Colorado Water Quality Control Commission (WQCC). The

new temperature criteria for Colorado's surface waters (Regulation No. 31, Basic Standards and Methodologies for Surface Water, 5 CCR 1002-31) are more stringent (lower) than the temperature standards reported in the DEIS and WQTR Tables. Although the WQCC adopted an interim temperature standard of 20ºC for cold water Segment 10 of the Poudre River, it appears that the intention of the WQCC is to adopt the more stringent standard in the June 2009 South Platte Basin Rulemaking Hearing. Due to these more stringent water temperature standards, the Corps should further model and evaluate the potential for the proposed action to violate these new standards. Without water temperature modeling, the nature and extent of potential adverse impacts of higher temperatures on the Poudre River cannot be accurately assessed or evaluated. Furthermore, the Corps must fully address these impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.7 of these Comments. *See also* Summary of Regulatory Impacts to Poudre River Water Quality in Section III.2c, below.

DEIS Section: 4.2.1.1 Changes to Poudre River Flows, page 4-5
Statement: *"The District's Proposed Action (Glade Reservoir and SPWCP) would reduce average monthly streamflow at the Lincoln Avenue gage in most months in most years…"*

Comment: Low flows aggravate the effects of water pollution. Dilution is the primary mechanism by which the concentrations of pollutants are reduced. During low flow, there is less water available to dilute loadings to the River, resulting in higher in-stream concentration of pollutants. Stream water temperatures also increase during low-flow periods, which add stress on aquatic ecosystems by reducing the ability of water to hold dissolved oxygen. See Section 404(b)(1) Guidelines Section 230.22 and 230.31.

The DEIS's analysis of these issues is inadequate. The Corps must evaluate and address the adverse water quality impacts from the substantial reductions in flow from NISP and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

DEIS Section: 4.5 Surface Water Quality, page 3.34
Statement: "*The uppermost wastewater treatment plant on the Poudre River is the City of Fort Collins WWTP near Lincoln Street and the lowest is City of Greeley's WWTP east of Greeley. With streamflow reductions, total ammonia concentrations in the river would increase below all of the WWTPs; however, ammonia concentrations up to a certain concentration are efficiently removed or transformed as the water moves downstream.* ***Stream temperatures would likely increase due to decreased flows*** *[emphasis added], which would increase unionized ammonia concentrations and could* ***reduce oxygen diffusion*** *[emphasis added] to the water column,* ***potentially enhancing biological activity in the river*** *[emphasis added]. While this could result in decreased nutrient concentrations in the river, it could create problems associated with* ***increased algal biomass in the river****." [Emphasis added].*

Comment: The DEIS does not provide any data or modeling regarding the nature or extent of projected water temperature increases or subsequent reduced dissolved oxygen levels in the

Poudre River through Fort Collins. To accurately evaluate the effects of warmer water temperatures on the aquatic species present in the River through the City, data and modeling are needed that define the aquatic species present, their life stage and whether the anticipated temperature increases would exceed either or both the acute or chronic stream standards. It should be noted that application of any "warm water" standard to address the temperature impacts ignores the fact that cold water species currently exist in the River in Fort Collins. Cold water species have higher dissolved oxygen requirements and less tolerance of increased water temperatures than warm water species. The potential adverse impacts to the River and aquatic species of warmer water temperatures and reduced dissolved oxygen levels are significant. However, those effects cannot be defined because of a lack of quantifiable data in the DEIS.

Increasing algal biomass in the River violates the central core of the narrative nutrient standard (A)(7) in the Clean Water Act §305(b) water quality assessment and §303(d). The narrative nutrient standard states:

> *"A surface water shall be free from pollutants in amounts or combination that…cause the growth of algae or aquatic plants that inhibit or prohibit the habitation, growth, or propagation of other aquatic life or that impair recreational uses…"*

Furthermore, "…increased algal biomass…" is a core concern under Sections 230.22 (water), 230.31 (fish and other aquatic organisms), 230.40 (sanctuaries and refuges), 230.51 (recreational fisheries), 230.52 (water-based recreation) and 230.54 (parks and similar preserves) of the Section 404(b)(1) Guidelines.

The inconsistent, undetailed and non-quantitative analysis of these important water quality issues fails to pass muster under either the Clean Water Act or NEPA and necessitates a fuller analysis in an SDEIS and revised Section 404(b)(1) Analysis. Increased algal biomass and other serious water quality impacts would impair the City's parks, Natural Areas, recreational use of the River and aesthetics and public enjoyment of the River. The Corps must evaluate and address these adverse impacts from the substantial reductions in flow from NISP and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

The language cited above from Section 4.5 of the DEIS appears at least twice again in Appendix D (see the following two excerpts from the DEIS below). However, in one instance, a projected temperature "increase" becomes a "decrease". It is implausible that reducing stream flows would result in a decrease in stream temperatures during the summer months of greatest concern.

DEIS Appendix D – Section 404(b)(1) Analysis, Section 2.3.1. Direct and Indirect Effects to Water, page D-5

General Comment: The 404(b)(1) analysis fails to provide a clear water depletion analysis that address handling, absorption, and evaporation losses from the various alternatives. Given the location of the facilities, these losses are likely very large and could influence the ability of the alternatives to meet demands without creating larger impacts down stream.

DEIS Appendix D -- Section 404(b)(1) Analysis, Section 2.3.2. Water Quality Effects Common to All Action Alternatives, page D-7
Statement: *"The uppermost wastewater treatment plant on the Poudre River is the City of Fort Collins WWTP near Lincoln Street, and the lowest is Greeley's WWTP east of town. With streamflow reductions, total ammonia concentrations in the river would increase below all of the WWTPs; however, ammonia concentrations up to a certain concentration are efficiently removed or transformed as the water moves downstream. Stream temperatures would likely increase due to decreased flows, which would increase unionized ammonia concentrations and could reduce oxygen diffusion to the water column,* ***potentially enhancing biological activity in the river*** *[emphasis added].* ***While this reduction in temperatures could result in decreased nutrient concentrations in the river*** [emphasis added], *it could also create problems associated with increased algal biomass in the river. Total organic carbon concentrations would be expected to decrease due to reduced streamflows, while selenium concentrations may increase. Predicted changes in metal concentrations (increases and decreases) in the Poudre River due to NISP are expected to be small and may not be measurable."[Emphasis added].*

And;

DEIS Appendix D – Section 404(b)(1) Analysis, Alternatives 2 and 4 – Glade Reservoir and the SPWCP, pages D-9 and D-10
Statement: *"The uppermost wastewater treatment plant on the Poudre River is the City of Fort Collins WWTP near Lincoln Street, and the lowest is Greeley's WWTP east of town. With streamflow reductions, total ammonia concentrations in the river would increase below all of the WWTPs; however, ammonia concentrations up to a certain concentration are efficiently removed or transformed as the water moves downstream. Stream temperatures would likely increase due to decreased flows, which would increase unionized ammonia concentrations and could reduce oxygen diffusion to the water column,* ***potentially enhancing biological activity in the river. While this increase in stream temperature and reduction in oxygen diffusion could result in decreased nutrient concentrations in the river*** *[emphasis added],* ***it*** *could also create problems associated with increased algal biomass in the river. Total organic carbon concentrations would be expected to decrease due to reduced streamflows, while selenium concentrations may increase. Predicted changes in metal concentrations (increases and decreases) in the Poudre River due to NISP are expected to be small and may not be measurable." [Emphasis added].*

Comment: As noted above, it is implausible that reducing stream flows would result in a decrease in stream temperatures during the summer months of greatest concern. Real-world experience would indicate that reduced river flows will result in <u>increased</u> water temperatures during the summer and fall seasons. Conclusions drawn on the basis of decreased temperatures with reduced flows are incorrect.

DEIS Section: 4.5.6 Glade Reservoir, page 4-35
Statement: *"…water would be supplied through runoff in the watershed (Lewis 2003; HDR 2007c)?"*

Comment: The report "HDR 2007c" does not appear on page 7-7 of the References and that phrase does not appear anywhere else in the document. The report is not posted at the Corps

website. It appears to be an important water quality report related to NISP that should have been made available to the public as part of DEIS record.

DEIS Section: 4.5.9 Mitigation, page 4-36
Statement: *"From the mouth of Poudre Canyon to the west side of Fort Collins, where the Poudre River is cold enough throughout the year to support trout populations and cold water invertebrates, water quality impacts and impacts to aquatic life that would occur during the winter months could be mitigated by increasing winter flows by 10 cfs or more. Diversions of water from the Poudre River could be timed, reduced or avoided during periods of hot weather and/or when the river temperature is chronically above a temperature at or above 20ºC at key locations for cold water aquatic life. This would likely be during July, August, and the first week of September. River diversions for the Project could be taken only during the coolest part of the day, from approximately midnight to mid-morning."*

*"To mitigate water quality effects that may occur from Fort Collins to the mouth of the Poudre River, **advanced wastewater treatment** (emphasis added) may be required to meet effluent limits at lower flows and warmer stream temperatures. In addition, agricultural return flows could be treated prior to discharge to the Poudre and South Platte rivers."*

Comment: The Corps' permitting decision cannot rely upon and assume mitigation supplied by third parties that are injured by the effects of the proposed project on the aquatic ecosystem. Further, the Corps must first fully evaluate adverse water quality impacts from the substantial reductions in flow from NISP and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

If, because of reduced river flows (less dilution water) and subsequent higher water temperatures in the Poudre River due to any NISP operations, Fort Collins' NPDES wastewater discharge permits should require implementation of advanced wastewater treatment (AWT) to meet more stringent effluent discharge limits, the associated costs would be significant. Current professional engineering estimates for design and construction of AWT in Fort Collins range from $75 million to $125 million, plus significant additional annual operation and maintenance costs (Fort Collins WWTP Design Team 2008 Conceptual Estimate).

2b. Comments on Water Quality Technical Report

(Northern Integrated Supply Project Environmental Impact Statement. Water Quality Technical Report (WQTR). March 2008. ERO Resources & HDR Engineering, Inc.)

WQTR Section: Table of Contents, Page ii
Statement: *"Table 5. Cache la Poudre River water quality values, 1980 to 2004. ..... page 23"* is transformed on page 23 into *"Table 5. Cache la Poudre River water quality values, 1980-2004. Cache la Poudre above North Fork (USGS gage 06749500)."*

Comment: The title of Table 5 was changed between Table of Contents and the title text on page 23 in the WQTR. The title in the Table of Contents gives an incorrect description of the contents of the Table 5 on page 23; it is not water quality data from above the North Fork of the Poudre River. In addition, the period of record stated in both the table of contents and the title of Table 5 for USGS site 06749500 is not correct. The period of record is 24 October 1979 through 21 September 1984, approximately five years of data, and not an extensive 24-year record of data collection (1980 through 2004) as suggested in the WQTR.

WQTR Section 7.2.1.1 Poudre River at the Canyon Mouth, page 36
Statement: *"The quality of the river at this location is very good (Table 5, USGS gage 06752000)."*

Comment: Table 5 page 23 of the WQTR presents data from USGS site 06749500 from the North Fork of the Poudre River just before its confluence with the main-stem of the Poudre River. The data depicted in Table 5 are not data for USGS gage site 06752000 for the Poudre River at the mouth of the canyon. The intent of the authors is not known but possibly they were referring to the un-numbered table on page 24 of the WQTR, "Cache la Poudre at Mouth of Canyon (USGS gage 06752000)" which is not identified in the Table of Contents.

WQTR Section: 7.2.1.2 Poudre River at Shields Street, page 37
Statement: *"The largest percent decreases [in flow] would occur in an average year at LINCGAGE in May (-71 percent), June (-54 percent), July (-47 percent) and August (-30) percent). During low flow months, the largest percent flow decrease in an average year at LINCGAGE would occur in January (-20 percent or -3.3 cfs)."*

Comment: Decreases in flow at the LINCGAGE (USGS Lincoln Street Gage) during low flow months have the potential to impact the Fort Collins Wastewater Treatment Plant (WWTP) at Mulberry Street. Because discharge permit limitations are based on low flow conditions, the Colorado Department of Public Health and Environment (CDPHE) Water Quality Control Division determines the discharge permit limitations for WWTPs using a defined critical low-flow condition. The critical low-flow condition is calculated using a 30-day average low flow with an average 1-in-3 year recurrence interval (30E3) for chronic standards, (except for temperature limitations, which use the empirically based 7-day average low flow with an average 1-in-3 year recurrence interval (7E3)), and the empirically based 1-day low flow with an average 1-in-3 year recurrence interval (1E3) for acute standards, or the equivalent statistically-based flow. For some pollutants, including ammonia, the low flow exceptions are based on periodic or seasonal flows (5 CCR 1002-31). A reduction in flow during low flow months will result in more stringent permit limitations for the Fort Collins WWTP, which will result in the need for advanced wastewater treatment (AWT) technologies to meet those permit limitations.

The table below depicts the river flow basis for specific treated wastewater effluent limits potentially affected by NISP. The table demonstrates that the majority of the parameters affected by NISP are either low-flow based, or are dependent upon a parameter that is low-flow based.

River Flow and/or River Water Quality Basis for Regulated NPDES Permit Limitation Calculations for Treated Wastewater Effluent Limits Potentially Affected by NISP:

NPDES Parameter	River Annual Low Flow-based Limit	River Monthly Low Flow-based Limit	Other River Flow-Based Limit	River Water Quality-based Limit	River Water Temperature-based Limit	River pH-based Limit	Limit based on Set Standard
pH[6]							X
Water Temperature[7]	X			X			
Dissolved Oxygen[8]			X	X	X		
E. coli[9]	X			X			
Ammonia[10]		X		X	X	X	
Metals[11]	X			X			

[6] pH limitations are based on a water quality standard of 6.5 – 9 pH units and are applied as instantaneous limits.
[7] Water temperature limitations are based on 7 day average low flow with an average 1-in-3 year recurrence (7E3).
[8] Dissolved Oxygen limitations are based on average conditions of temperature and flow for the worst case time period.
[9] E. Coli limitations are based on 30 day avg low flow with an average 1-in-3 year recurrence (30E3).
[10] Ammonia limitations are calculated as monthly limits and are dependent on the pH, temperature, and quality of the receiving stream.
[11] Metals limitations are calculated as acute limits, based on 1 day low with an average 1-in-3 year recurrence (1E3); and as chronic limits, based on 30 day average low flow with an average 1-in-3 year recurrence (30E3).

The Corps must evaluate and address the adverse water quality impacts from the substantial reductions in flow from NISP and must fully address the expected impacts, including the increased wastewater treatment systems required as a result, in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

Current professional engineering estimates for design and construction of AWT in Fort Collins range from $75 million to $125 million, plus significant additional annual operation and maintenance costs (Fort Collins WRF Design Team 2008 Conceptual Estimate).

WQTR: Table 9 Cache la Poudre River water quality analysis locations page 36
Statement: The 4th row states *"Prospect Street east of Fort Collins – South Fort Collins Sanitation District WWTP discharge point"*.

Comment: The statement in the table is incorrect. The South Fort Collins Sanitation District (SFCSD) effluent is discharged into Fossil Creek Reservoir. Waters from Fossil Creek Reservoir, in turn, are discharged to the Poudre River downstream of the Boxelder Sanitation District (BSD) at a location east of Interstate 25. As a result of that error in discharge point location shown in Table 9, any reported modeling, mass balance equations, etc., as well as any subsequent narrative or conclusions included in either the WQTR or DEIS that are derived from that error of fact may be incorrect. The City cannot adequately assess, evaluate or discuss this and related portions of the DEIS because of these errors of fact in the WQTR. The Corps must correct these errors and provide updated analyses in an SDEIS and Revised 404(b)(1) Analysis for this project.

WQTR Section: 7.2.1.3 Poudre River at Fort Collins WWTP, page 38
Statement: *"Based on previous sampling results, reduced flows would likely increase stream temperature during the spring and summer months, increase unionized ammonia concentrations, decrease DO concentrations…"*

Comment: Water quality is an important component of the physical environment for aquatic species. Small changes in some chemical constituents can result in changes to the biological community. The WQTR used existing data from USGS and other sources to describe the baseline conditions. Most of the analysis relied on professional judgment and did not present quantified information regarding changes in key water quality parameters that are biologically meaningful. Water temperature impacts on aquatic resources was identified and listed as a key issue during scoping; however, no water temperature simulations were conducted to determine the biological effects to the aquatic fauna in the study area.

The impacts of reduced flows described all result in a degradation of water quality and will most likely impair or prevent the ability of this section of the Poudre River to remain suitable for its beneficial uses as determined by the Colorado Department of Public Health and Environment

(CDPHE) for recreation and aquatic life use. Increases in stream temperature, and a reduction in dissolved oxygen concentrations can affect the survival of aquatic life and reduce recreational opportunities. See Section 404(b)(1) Guidelines Sections 230.22 and 230.31. Due to the seriousness of the potential effects and their critical role in the analysis of effects under the Section 404(b)(1) Guidelines, the Corps must provide more detailed and quantitative analysis of these water quality impacts in an SDEIS, Revised 404(b)(1) Analysis and subsequent documents.

WQTR: Cache la Poudre at Lincoln Street (USGS gage 06752260), page 26
Statement: The table presented for water quality on the Cache la Poudre at the Lincoln Street Gage shows existing nitrate and nitrite concentrations ranging from 0.005 to 1.8 mg/l with a mean of 0.4 mg/l, with an observation that highest values occur at low flow and lowest values at high flow. In addition, total phosphorus concentrations are reported to range from 0 to 0.7 mg/l with a mean of 0.02, with highest values from July – September.

And;

WQTR Section 7.2.1.2, Poudre River at Shields Street, page 38
Statement: *"A dissolved oxygen concentration less than the spawning standard of 7 mg/l has occurred in the past; with reduced flows and water stream temperatures, the dissolved oxygen standards could be more frequently exceeded during the summer months. Nitrite and pH concentrations could exceed standards more frequently due to reduced streamflows."*

Comment: Data from the chart on page 26 of the WQTR state that high nutrient values are linked to low flow conditions. However, page 38 of the technical report, which discusses in detail other water quality impacts, does not discuss expected increases in nutrient concentrations associated with low flows. The Colorado Water Quality Control Commission (WQCC) will adopt numeric criteria for nutrients in rivers and streams in June 2010. Increased nutrient concentrations in the Poudre River resulting from NISP would cause the development and enforcement of more stringent limits in the City's wastewater discharge permits. In turn, this would likely require the added expense of designing, operating and maintaining advanced wastewater treatment (AWT) systems at the City's two water reclamation facilities to meet the more stringent limits. In fact, the operation of AWT in Fort Collins is already stated as a likely outcome of NISP (Section 4.5.9 Mitigation, p. 4-36).

Current professional engineering estimates for design and construction of AWT in Fort Collins range from $75 million to $125 million, plus significant additional annual operation and maintenance costs. The Corps must fully address these expected impacts from NISP in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

WQTR Section: 7.2.1.3. Poudre River at Fort Collins WWTP, page 39
Statement: *"…total ammonia and dissolved copper concentrations are available for the Fort Collins WWTP and for the Poudre River below the WWTP (at Mulberry Street), a mass balance*

analysis was completed for May, June, July, and August ***(water quality data for other parameters are not available for both the WWTP and the river at Mulberry Street).*** *"* [Emphasis added]

Comment: The emphasized portion of the statement is incorrect. Over ten years of detailed multi-parameter water quality data through the Spring of 2008 is available for both the Mulberry Wastewater Treatment Plant (WWTP) and for the Poudre River below Mulberry Street and above Prospect Street. The data includes dissolved selenium, arsenic, silver, cadmium, chromium, copper, lead and zinc; total recoverable iron and manganese, hardness, temperature, pH, ammonia-nitrogen, nitrite-nitrogen, and nitrate-nitrogen. Much of this data is available via the Colorado Data-Sharing Network on EPA's STORET internet database under the organization ID of "CITYFTCO" and station ID of "PBRY". Due to these omissions of analysis from the WQTR, the mass loading calculations, narrative, and conclusions drawn in the WQTR report for Poudre River at the Mulberry WWTP are incomplete and inaccurate. The City cannot adequately assess, evaluate or discuss this and related portions of the DEIS because of these errors of fact and omission in the WQTR. These data must be incorporated in updated analyses in an SDEIS and subsequent documents to address these important water quality questions.

WQTR Section: 7.2.1.4., page 40
Statement: Poudre River at South Fort Collins Sanitation District. *"…at the nearest USGS water quality monitoring site (USGS gage 06752270), …".*

Comment: This statement is incorrect. Site 06752270 is not the nearest USGS site to the South Fort Collins Sanitation District (SFCSD). USGS site 06752270 is the water quality site on the Poudre River just above East Prospect Street in Fort Collins. This USGS site is above the discharge points for both City of Fort Collins Drake Water Reclamation Facility (DWRF) and the Boxelder Sanitation District (BSD) plant. Site 06752270 at Prospect is several miles above the discharge point for the SFCSD plant into Fossil Creek Reservoir. Site 06752270 has never had a flow gage. However, there is a USGS water quality monitoring continuous flow gage station (06752280) on the Poudre River downstream of the DWRF and just above the confluence of the Poudre River with Boxelder Creek. It is located on the Poudre River just upstream of discharge point for BSD. Site 06752280 has over 25 years of continuous flow and monthly water quality data. All of the USGS data for site 06752280 is available via the USGS website on the Internet. However, the WQTR authors failed to use any of this flow or water quality data for their modeling, analysis, discussion or conclusions.

Furthermore and in addition to the USGS dataset at station 06752280, the City of Fort Collins has also collected weekly and monthly water quality data on the Poudre River at the USGS Boxelder gage site for over ten years. The data includes values for dissolved arsenic, selenium, silver, cadmium, chromium, copper, lead and zinc; total recoverable iron, mercury, and manganese, as well as hardness, temperature, pH, ammonia-nitrogen, nitrite-nitrogen, and nitrate-nitrogen. Much of this data is posted on EPA's STORET database.

A table from the USGS on the extensive water quality and flow datasets available for the Boxelder Gage site (06752280) is given below:

USGS 06752280 Cache la Poudre River Above Boxelder Creek, Near Timnath, CO			
6752280	Latitude 40°33'07", Longitude 105°00'39"	Larimer County, Colorado, Hydrologic Unit 10190007

Field/Lab water-quality samples	5/22/1972	9/20/2005	467

The City cannot adequately assess, evaluate or discuss this and related portions of the DEIS because of these errors and omissions of fact in the WQTR. The use of less representative data from farther-away sites renders the analysis and conclusions unreliable. The most representative

data must be incorporated in updated analyses in an SDEIS and subsequent documents to address these important water quality questions.

WQTR Section: 7.2.1.4. Poudre River at Fort Collins WWTP, pages 38-39
Statement: Entire section.

Comment: The WQTR never mentions either the existence of or potential impacts associated with the City of Fort Collins' Drake Water Reclamation Facility (DWRF) on the Cache la Poudre River in relation to NISP. The DWRF is a National Pollutant Discharge and Elimination System- (NPDES-) permitted 23 million gallons per day (mgd) wastewater treatment plant located at 3036 Environmental Drive, Fort Collins Colorado.

The WQTR does not mention any modeling or analysis of DWRF discharge to the Cache la Poudre from its NPDES-permitted discharge point 002A described for permit number CO-0047627. At build-out, the DWRF is expected to have a rated flow capacity of 31.3 million gallons per day (mgd). The failure to include a thorough analysis and discussion of the DWRF discharge, the single largest potential treated wastewater discharger on the Poudre River, makes the WQTR modeling results incomplete, unreliable and inaccurate. Furthermore, the subsequent written discussion, comments, justifications, recommendations, and conclusions drawn from the WQTR for this portion of Segment 12 of the Cache la Poudre River may, in turn, also be incomplete, unreliable and inaccurate.

The City cannot adequately assess, evaluate or discuss this and related portions of the DEIS because of these errors of fact and omissions in the WQTR. Data regarding the DWRF must be incorporated in updated analyses in an SDEIS and subsequent documents to address these important water quality questions.

WQTR Section: 7.2.1.4 Table 10, page 39
Statement: Poudre River at Fort Collins WWTP, *"… a mass balance analysis for May, June, July, August (water quality data for other parameters are not available for both the WWTP and the river at Mulberry Street)."*

Comments: The modeling results described in the Table 10 of the WQTR and the resulting discussion, comments and conclusions are incomplete. A critical month, September, for which data is available, was omitted from the analysis. September is critical because of the combination of low river flows in that stretch of the Poudre River and end-of-summer warm water temperatures. This omission underestimates the modeled and potentially adverse water quality impacts. In addition, the phrase, "…(water quality data for other parameters are not available for both the WWTP and the River at Mulberry Street)" is not correct; several years of corresponding effluent and river data are available. Furthermore, there is no documentation in the WQTR of the river flows (Q1, below) or wastewater discharge flows (Q2), or combined flows (Q3) used in the mass balance calculations. The formula for mass balance equations (taken from CDPHE Water Quality Assessment, Cache la Poudre River, Ft. Collins WWTF'S, 18 December 2007) is:

$$M_2 = \frac{M_3 Q_3 - M_1 Q_1}{Q_2}$$

Where,
Q1 = Upstream low flow (1E3 or 30E3)
Q2 = Average daily effluent flow (design capacity)
Q3 = Downstream flow (Q1 + Q2)
M1 = In-stream background pollutant concentrations at the existing quality
M2 = Calculated maximum allowable effluent pollutant concentration
M3 = Maximum allowable in-stream pollutant concentration (water quality standards)

The critical flow values used to create all of the mass balance results reported in Tables 10, 11, 12 13,14,15,16,17,18,19,20,21, and 22 are not reported. It is not clear whether the full rated maximum treatment capacities of all NPDES-permitted discharges were used in the modeling. Furthermore, no information is provided regarding the wasteload allocation assumptions that were used for nearby dischargers.

To only report wasteload allocation calculations in the WQTR is of no value in analyzing potential adverse impacts of NISP on NPDES dischargers to Segments 11 and 12 (COSPCP11 and COSPCP12) of the Poudre River. To derive meaningful information regarding potential adverse impacts, three modeling tasks must be completed together. These modeling tasks are: Total Maximum Daily Load (TMDL) calculations, wasteload allocation modeling, and mass balance calculations. These modeling tools are used routinely to develop, apply, meet and enforce NPDES discharge permit limits for the key point-source dischargers that operate on the Poudre River.

With reduced flows in the River proposed by NISP, the roles of pollutant mixing, dilution, and assimilative capacity of the River become ever more critical. Allocating wastewater discharge volumes and strength (or wasteloads) between nearby dischargers on a waterway is now a tool being routinely applied by the Colorado Department of Public Health and Environment (CDPHE) to develop NPDES discharge permits. Wasteload allocation is used in addition to modeling "mass balance" calculations. The WQTR report includes mass balance results for selected parameters for just some pollutants discharged to the Cache la Poudre River. However, no wasteload allocation modeling was done. Wasteload allocation modeling should be completed and reported for all NISP alternatives to also include all key point-source NPDES dischargers to the Cache la Poudre River. Permitted dischargers include the City of Fort Collins, Boxelder Sanitation District, South Fort Collins Sanitation District, Town of Windsor, Kodak Colorado Division, and the City of Greeley. Failure to perform these modeling tasks may underestimate potential adverse impacts of NISP on these permitted dischargers and the Cache la Poudre River.

There is no mention in the WQTR of either "acute" or "chronic" total ammonia discharge limits that are common to all the NPDES discharge permits for all of the major municipal water reclamation and sanitation districts that discharge to the Poudre River. These are the same communities and sanitation districts that will bear the burdens of operating and maintaining

treatment systems to meet ever more stringent wastewater discharge limits resulting from NISP. Both acute and chronic total ammonia limits should be calculated using both the Colorado Ammonia Model (CAM) and the Colorado AMMTOX model for these key point-source dischargers under the various reduced flow regimens resulting from NISP and presented in an SDEIS and subsequent documents..

The DEIS fails to provide adequate data, modeling and analysis of these critical wastewater pollutant discharge and river water quality issues. The Corps must evaluate and address these issues and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

Deteriorating water quality in the Poudre River resulting from NISP-caused reductions in flows would cause the development and enforcement of more stringent limits in the City's wastewater discharge permits, whether or not new "nutrient standards" (discussed below) are adopted. In turn, this would likely require the added expense of designing, operating and maintaining advanced wastewater treatment (AWT) systems at the City's two water reclamation facilities to meet the more stringent limits. In fact, the construction and operation of AWT systems in Fort Collins is already identified as a likely outcome of NISP (DEIS Section 4.5.9 Mitigation, p. 4-36).

The "nutrient standards" currently being developed by CDPHE will likely result in extreme reductions in allowed levels of pollutants such as phosphates and nitrogen that can be discharged to the River. The City and other permitted dischargers to the River are generally aware that nutrient standards are on the regulatory horizon. As a consequence, the nutrient standards and subsequent discharge regulations place AWT on the 20-year strategic planning, design, construction, operation and maintenance horizon for NPDES-permitted dischargers to the River. Current professional engineering estimates for design and construction of AWT in Fort Collins range from $75 million to $125 million (net present value), plus significant additional annual operation and maintenance costs. A 20- year planning horizon gives the City time to incorporate these projected costs into its Wastewater Utility rate structure. However, the projected river flow reductions and corresponding deterioration of Poudre River water quality resulting from NISP turn that long-term planning horizon on its head: under its proposed schedule, NISP would be on-line and nutrient standards enforced in the City's discharge permits on or shortly after 2014 – requiring massive wastewater treatment upgrades more than a dozen years sooner than would otherwise be necessary. This time squeeze would place an extreme financial burden on Fort Collins wastewater ratepayers.

2c. Summary of Regulatory Impacts to Poudre River Water Quality

Summary of Regulatory Impacts of NISP Operations on the Poudre River from the foothills through the City of Fort Collins.

Water Quality Parameter	Affected Stretch of River	Stream Standard	Current Status	Impact of NISP
pH	Poudre from Monroe Canal to Shields St.	6.5 – 9.0 pH units	Impaired; Listed on the CO 303(d) list of impaired waters	Increases in pH; further water quality impairment
Copper[d]	Poudre from Monroe Canal to Shields St.	7 µg/l (acute, dissolved) 5 µg/l (chronic, dissolved)	Impaired; Listed on the CO 303(d) list of impaired waters	Higher concentrations of Cu, further water quality impairment and impairment of aquatic life and recreational use
Water Temperature	Poudre from Monroe Canal to Shields St.	17°C (June – Sept) 9°C (Oct – May) Interim Std of 20°C[i]	Currently meets water quality standards	Increases in water temperature; further water quality impairment and impairment of aquatic life and recreational use
Aquatic Life Use	Poudre from North Fork to Shields St.	Aquatic Life Cold 2[e]	Listed on the CO Monitoring and Evaluation List	Further impairment of aquatic life use
E. coli	Poudre upstream of Boxelder Cr.	126 cfu/ 100 ml[a]	meets water quality standards	Higher concentrations ***of E. coli***, water quality impairment and impairment of water-based recreation
E. coli	Poudre downstream of Boxelder Cr to So Platte	126 cfu/ 100 ml[a]	Impaired; Listed on the 2008 CO 303(d) list of impaired waters	Higher concentrations ***of E. coli***, further water quality impairment and impairment of water-based recreation

Summary of Regulatory Impacts of NISP Operations on the Poudre River from the foothills through the City of Fort Collins (*continued*):

Water Quality Parameter	Affected Stretch of River	Stream Standard	Current Status	Impact of NISP
Selenium	Poudre downstream of Boxelder Cr to So. Platte	18.4 µg/l (acute[b]) 4.6 µg/l (chronic[c])	Impaired; Listed on the 2008 CO 303(d) list of impaired waters	Higher concentrations of Se, further water quality impairment and impairment of aquatic life use
Dissolved Oxygen	Horsetooth	6.0 mg/l 7.0 mg/l (sp[f])	Impaired; Listed on the CO 303(d) list of impaired waters	Impact unknown; NCWCD Study Group
Aquatic Life Use	Horsetooth	Aquatic Life Cold 1[g]	Impaired; listed on the Colorado 303(d) list for Mercury FCA[h]	Unknown impact on 303(d) listing or Hg

a/ Geometric mean of a representative sample set.
b/ Acute Standard means the level not to be exceeded by the concentration for either a single sample or calculated as an average of all samples collected during a one-day period.
c/ Chronic Standard means the level not to be exceeded by the concentration for either a single representative sample or calculated as an average of all samples collected during a thirty-day period.
d/ Copper water quality standards are hardness dependent; values listed assume a hardness of 50 mg/L, based on USGS data (USGS 2006) (See NISP Water Quality Technical Report).
e/ Aquatic Life Cold 2 means surface waters currently not capable of sustaining a wide variety of cold water biota, including sensitive species, due to physical habitat, flows, or water quality conditions.
f/ Sp = spawning season. Spawning criteria are to be applied on a seasonal basis where the Division determines that the habitat that will be affected by the physical mixing zone is suitable for spawning by fish species that are expected to be present.
g/ Aquatic Life Cold 1 means surface waters currently capable of sustaining a wide variety of cold water biota, including sensitive species.
h/ FCA = Fish Consumption Advisory.
i/ An interim standard of 20ºC was adopted for cold water segments in the South Platte River Basin until the June 2009 South Platte Basin Rulemaking Hearing.

3. Trichloroethylene (TCE)

DEIS Executive Summary: page ES-8
Statement: *"TCE contaminated ground water located in the vicinity of the forebay will require mitigation efforts associated with forebay construction activities."*

And;

DEIS Section: 3.23.3 Glade Reservoir Forebay, page 3-126
Statement: *"The forebay is planned to be isolated from the ground water table by installation of perimeter slurry walls keyed into unweathered bedrock."*

Comment: The Lyons Formation will be extensively exposed within the footprint of the proposed forebay. Therefore, attempting to isolate the forebay from the water table with perimeter slurry walls will not isolate it from the underlying TCE plume in water-bearing zones within the Lyons Sandstone. Furthermore, if the forebay is completely lined (sides and bottom) with an impermeable liner as described in DEIS Section 5.10, the potential for offsite movement of the trichloroethylene (TCE) plume must be evaluated. Additional seasonal monitoring and subsequent groundwater modeling is required to accurately assess the potential for groundwater interaction with and migration of the TCE plume under NISP project conditions. Potential adverse impacts of the TCE contaminated groundwater can not be adequately assessed or accurately evaluated because of this lack of monitoring and modeling. An SDEIS must be prepared that includes this information. This information is essential for the Corps to discharge its obligations under Section 230.22 of the Section 404(b)(1) Guidelines relating to the effects of a proposed permitted activity on water quality.

DEIS Section: 3.23.3.1 TCE Plume, page 3-126
Statement: *"The second water-bearing zone was encountered at an elevation depth of about 5,230 feet (~40 to 50 feet below ground surface (bgs)) in the western and northern portions of the northwest area of the proposed forebay. The second water-bearing zone was encountered at an elevation depth of 5,225 feet (~25 feet bgs) in the southeast corner of the proposed forebay at monitoring well NCWCD and at about 5,218 feet (~30 feet bgs) in the southwest corner of the proposed forebay at monitoring well 13-MW22. Ground water concentrations ranged from nondetect to 74.6 µg/L for TCE within the second water-bearing zone."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-126
Statement: *"The third water-bearing zone was encountered at an approximate elevation depth of 5,220 feet (~50 feet bgs) in the western portion of the northwest area of the proposed forebay. Groundwater concentrations ranged from nondetect to 42.7 µg/L for TCE within the third water-bearing zone."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-126
Statement: *"The second, third, and fourth water-bearing zones are semi-confined and have an upward vertical gradient."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-127
Statement: *"Seasonal monitoring was not performed as part of the Corps Remediation Investigation and, as a result, seasonal fluctuations in TCE concentrations and groundwater elevations have not been assessed. Based on methods reported by the Corps, ground water elevation measurements and sampling were not conducted for all wells during one sampling event. Instead, reported ground water elevations and sampling results were either conducted in December 2003, January 2004, or May 2004, and represent data collected over a range of seasonal conditions."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-127
Statement: *"TCE concentrations in ground water above the Colorado standard of 5 µg/L have not been detected beneath the proposed forebay within the second or third water-bearing units."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-127
Statement: *"Ground water from the second water-bearing unit is expected to be encountered during excavation activities within the southern half of the forebay."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-127
Statement: *"TCE concentrations in ground water beneath the northwest corner of the proposed forebay are anticipated to be just below the Colorado standard."*

And;

DEIS Section: 3.23.3.1 TCE Plume, page 3-127
Statement: *"Although TCE contaminated ground water above the Colorado standards is not anticipated, potential seasonal variations in TCE concentrations and ground water depth were not evaluated during the Corps' site characterization and as a result, the exact TCE concentration and depth of ground water within the proposed forebay is unknown. The proposed forebay location and depth is subject to change based on potential pilot boreholes and initial excavation activities."*

And;

DEIS Section: 4.7.2 Glade Reservoir, page 4-38
Statement: *"If seepage enters the Lyons Formation, there would be additional dilution of the already low TCE concentrations. Because seepage from the reservoir would either follow topography downstream of the dam and/or move down a structural dip in the bedrock units, the source area for the TCE plume would not likely be affected by the reservoir."*

And;

TCE Technical Memorandum – Glade Forebay, page 3
Statement: *"… the MWH design would require the forebay to be constructed to a lower depth so that the forebay will be filled by gravity…, the MWH design is currently proposed to avoid the use of a pump station."*

Comment (applies to all above Statements): The DEIS conclusion that trichloroethylene (TCE) concentrations above the Colorado standard of 5 µg/L have not been detected beneath the proposed forebay for Glade Reservoir within the second or third water-bearing units is based on very limited sampling in late 2003 and early to mid-2004. Only 3 monitoring wells were located in the area of the proposed forebay footprint itself. Significantly higher TCE concentrations (74.6 and 42.7 µg/L in the second and third water-bearing formations, respectively) were found approximately ¼ mile northwest (upgradient) from the northwest portion of the proposed forebay (ERO, November 22, 2006).

Review of the DEIS, supporting documents and technical reports does not reveal any potentiometric mapping of hydraulic heads in the water-bearing units that have been impacted by past TCE releases. Therefore, accurate delineation of ground water flow direction and rate of movement are lacking. Considering that groundwater flow in the Lyons Formation is described as upward in the area of the proposed forebay, and that the water-bearing units are semi-confined (i.e., "leaky"), the potential for future migration of TCE-contaminated groundwater, including potential offsite movement caused by project-related changes in hydraulic heads, has not been adequately assessed by the DEIS. Additional monitoring and subsequent groundwater modeling is required to accurately assess the potential for groundwater interaction with and migration of the plume under NISP project conditions. This information must be presented in an SDEIS for the project and in any subsequent documents.

Although an impermeable lining is proposed for the forebay to "*eliminate seepage losses/gains during operation of the forebay – page 5*", additional data must be gathered about the seasonality in groundwater levels and TCE concentrations. If seasonal groundwater levels are significantly higher than the forebay bottom elevation, there will be an ongoing potential for TCE to seep into the forebay, Glade Reservoir, and any connected water supply source including the Poudre River and Horsetooth Reservoir.

This situation will necessitate the treatment of the existing TCE plume(s) prior to the operation of Glade Reservoir. Treatment of TCE-contaminated aquifers is challenging and is the subject of ongoing research.

We have reviewed the "DRAFT FINAL - FEASIBILITY STUDY REPORT - F.E. WARREN AIR FORCE BASE FORMER ATLAS "E" MISSILE SITE 13, LAPORTE, COLORADO" Report prepared by the U.S. Army Corps of Engineers, Omaha District in January 2007 (the 2007 Feasibility Study Report). In this Report, page ES-2 states: "The discharge point of the regional aquifer is interpreted from groundwater flow direction to be the Cache la Poudre River located south of the site."

Simply put, not treated, TCE-contaminated groundwater will eventually reach the Poudre River. Impacts from Glade Reservoir will: (1) increase groundwater levels at the vicinity of the Reservoir, including the TCE plume area; and, (2) lower the groundwater levels near the Poudre River as the flows in the River are reduced. *The net effect will likely be to speed TCE migration into the Poudre River.* This is a significant impact to the aquatic ecosystem that would not happen but for the proposed placement of the Glade Reservoir. This impact requires detailed consideration in an SDEIS, *See* Section 230.22 of the Section 404(b)(1) Guidelines.

On Page ES-2, the 2007 Feasibility Study Report notes that the maximum detected TCE concentration was 140 µg/L. This is about twice the value listed in the August 18, 2006, ERO TCE Tech Memo (Page 2). Furthermore, both values are substantially above the Maximum Contaminant Level (MCL) of 5 µg/L for TCE. It must also be noted that the MCL Goal (MCLG) for TCE is zero. The MCLG is the level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety and are non-enforceable public health goals. In general, the EPA sets MCLs as close to MCLGs as feasible using the best available treatment technology and taking cost into consideration.

The estimated groundwater velocity at 131.4 ft/year (page ES-2) is not based on pump tests as none have been performed at the site. It is well established that pump tests are the only means through which a reasonable estimate could be derived for groundwater aquifer properties and estimated velocities. Calibrated numerical models used in preparing the technical reports regarding the TCE plume and subsequently reflected in the DEIS will also suffer the same handicap as their parameters are not based on pump tests. In addition, more data are required to understand the existing seasonality in water levels and, perhaps, TCE concentrations at the site. Significant additional effort will be required to accurately monitor and evaluate the properties and movement of the groundwater TCE plume.

For risk assessment purposes, only the occupational worker and resident were identified as potential receptors of TCE. However, if the additional hydraulic gradient created by seepage from the proposed Glade reservoir results in faster groundwater migration towards the Poudre River, another important exposure pathway is thereby identified. This pathway could result in significant human and wildlife exposure to TCE and

requires extensive, detailed consideration in an SDEIS. This potential exposure pathway could prove to be significantly worse if an easier or preferential flow path is intercepted by the TCE plume toward the Poudre River.

It is noteworthy that the 2007 Feasibility Study Report states that groundwater flow is contained in the bedrock water-bearing zones and appears to be dependent on secondary porosity along fractures. Fractured flow at the site has not been reasonably characterized yet, but needs to be evaluated in light of the new possible groundwater exposure pathways due to Glade Reservoir.

The 2007 Feasibility Study Report identified five remediation alternatives for the TCE-contaminated groundwater: No Action, Monitoring and Aquifer Use Restrictions, Augmented Extraction and Treatment, Enhanced Reductive Dechlorination, and Chemical Oxidation. However, the evaluation of these alternatives was based on plume dimensions and configurations derived from groundwater modeling. As stated before, we find the data used to construct the model to be highly insufficient, especially with the possible increased hydraulic gradients due to reservoir seepage. This lack of data covers aquifer hydraulic parameters as well as the range of fluctuation over the seasons for water levels and TCE concentrations.

There are numerous potential environmental and public health risks associated with the TCE-contaminated groundwater plume located below and adjacent to the proposed forebay at the face of the Glade Reservoir dam. However, the DEIS essentially ignores all remediation proposals identified in the 2007 Feasibility Study Report. Rather than assess, evaluate, and address the contamination problem, the DEIS attempts to avoid the issue by following the tenuous path of adaptive management. However, adaptive management is a means of implementing mitigation – it is not a substitute for complete assessment and for consideration of significant impacts and how to address them..

Furthermore, the groundwater monitoring studies cited and used to develop the DEIS for the site were poorly designed and poorly executed. For example, no groundwater depths were measured at any of the monitoring wells during one sampling mission to the site. Yet seasonal real-world depth to groundwater data at the site's monitoring wells is essential to identify and then model the nature and extent of TCE contamination and plume movement in the area. No seasonal groundwater depth data were collected. No groundwater modeling craft for a project of this magnitude can withstand the burden of inadequate seasonal data; modeling forecasts become simply guesswork. Proposed steps identified in the DEIS to avoid, minimize the harm, or mitigate TCE groundwater contamination in the area are crippled by a lack of adequate monitoring data in the supporting documents used to develop the DEIS and therefore cannot be effectively evaluated at this time.

The failure of the DEIS to address this issue, including the complete failure to consider the effects of placing a large reservoir upgradient of the contamination, is a fundamental deficiency that requires an SDEIS and Revised Section 404(b)(1) Analysis.

4. NISP Operations

The following comments address a number of ways in which the DEIS is deficient due to its failure to provide sufficient information about how NISP will be operated. Without this information it is not possible to understand the potential impacts associated with NISP and for the Corps to adequately assess these impacts or address them in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments

4a. Comments on DEIS

DEIS Section: 2.3.1 Diversions from the Cache la Poudre River, page 2-25 (similar reference in DEIS Section 2.4.1.7, page 2-33 and elsewhere)
Statement: *"The proposed Glade Reservoir would also divert from the existing Munroe Canal diversion (Section 2.4.1.7)."*

Comment: The City, both as a North Poudre Irrigation Company shareholder and as a participant in the Pleasant Valley Pipeline (which diverts from the Munroe Canal), has considerable interest in how the Munroe Canal is used. Operational criteria and/or limitations need to be established that will avoid injury to any of the current users of the Munroe Canal.

DEIS Section: 2.3.3.1 Reclamation Contract Subalternative, page 2-27
Statement: *"The proposed exchange involves the annual delivery of 29,500 AF from Carter Lake to the NISP southern Participants, with equivalent replacement water to be released (1) from Glade Reservoir directly to the Poudre River to meet C-BT irrigation needs…"*

Comment: The City typically performs Colorado-Big Thompson (C-BT) exchanges with other water users in the Poudre River Basin that benefit the City. Since the District will be operating both the C-BT project and NISP, the District may impose conditions on C-BT uses that will favor the NISP/Glade exchanges over other exchanges such as those historically relied upon by the City. This additional potential impact to municipal water supplies must be assessed and addressed under the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments. Additional evaluation is needed to adequately address impacts that could be detrimental to the City and other water users in the Poudre River Basin because of the need to exchange 29,500 acre feet for use by the Southern Participants in NISP. NISP operations must avoid impacting the City's C-BT exchanges.

DEIS Section: 2.4.1.2 Participants' Ability to Purchase and Sell Participation in NISP, page 2-31
Statement: *"The ability to purchase and sell contracts in NISP would not alter the size or operation of NISP."*

Comment: Additional evaluation of the impact of transferring contracts is needed. Although transfer of NISP participation would likely not affect the way Glade Reservoir is filled, it could certainly affect the way Glade water is delivered. The delivery of NISP water from Glade Reservoir is split among Northern Participants and Southern Participants and will be performed in different ways, as discussed in DEIS Sections 2.3.3 and 2.3.4. If portions of NISP were transferred from the Northern Participants to the Southern Participants, it would require additional C-BT exchanges and/or would alter the amount of water that could be delivered through a Glade-to-Horsetooth pipeline, which could affect the water quality in Horsetooth. If portions of NISP were transferred from the Southern Participants to the Northern Participants (as those terms are defined in the DEIS), it could increase the amount of exchanges from Glade to the Munroe and into the Pleasant Valley Pipeline (PVP), reducing flows in those stretches of the River. These potential impacts need to be addressed.

DEIS Section: 2.4.1.3 Sources of Water for Initial Fill of Glade Reservoir, page 2-31 (also MEMORANDUM Northern Integrated Supply Project Environmental Impact Statement Impacts Due to Glade Reservoir Start-Up Diversions, October 16, 2007, page 7 of 15)
Statement: *"At the time of project start-up, NISP Participants will need approximately 10,000 to 15,000 AF of yield. If water is not available from the Grey Mountain water right, then other water sources could be considered by NISP Participants as interim supplies."*

Comment: These sections discuss using water rights as sources for the initial fill of Glade Reservoir other than those identified and modeled with the preferred alternative. The City has utilized some of these water sources in the past and may need to do so in the future, which may create competition for these sources. The use of these Poudre River Basin sources is not covered under the District's water rights for the NISP project. Further, the impacts of using Poudre River Basin sources (other than the NISP water rights) for this purpose have not been adequately evaluated. These potential impacts must be identified and analyzed in the SDEIS. To avoid potential impacts, Southern Participants should use Windy Gap water and/or Colorado-Big Thompson (C-BT) water rather than renting or buying water from Poudre River Basin irrigation companies (i.e., Grand River Ditch and/or Tunnel Water Company). If the use of non-NISP Poudre River Basin water rights is allowed, then appropriate limitations (such as volumetric and/or number of years) should be imposed on the use of these sources. In addition, the District must commit to a timeframe for bringing Galeton Reservoir on-line and minimize the need to use any additional start-up diversions from the Poudre River Basin.

DEIS Section: 2.4.1.4 Sources of Water for Drought Conditions, page 2-32
Statement: *"The District desires the ability to provide water to NISP in years when the annual divertible flows from the Poudre River fall below 20,000 AF."*

Comment: This section discusses using other water rights than those identified and modeled in the proposed alternative during drought years more severe than those modeled in the DEIS. The utilization of sources other than the NISP decreed flows (Grey Mountain right and the SPWCP rights and exchanges) to supply NISP participants could have a greater impact on river conditions through Fort Collins than that currently predicted and described in the analysis or these Comments. As discussed in Part IV of these Comments, the impacts from NISP to aquatic resources in and through Fort Collins are expected to be extensive and severe. In addition, to allow the utilization of NISP for non-NISP flows would open the door to the possibility of moving additional Poudre River Basin water rights (such as converted agricultural rights) through the NISP facilities and/or exchanges, and this would have an even greater impact to river conditions through Fort Collins. These potential impacts must be evaluated and factored throughout relevant sections of an SDEIS.

The District may be relying upon water provided by Poudre River Basin agricultural producers to supply water to NISP participants in the long-term, rather than relying on NISP decree water rights. To address the potential impacts associated with possible use of these Poudre River Basin sources, NISP participants must be required to reduce use, enter into dry-year leases, or acquire supplies within their own river basins. NISP must not be used to facilitate the transfer of water from Poudre River Basin agricultural lands to other basins, especially during severe drought events. Appropriate limitations must be imposed on the total amount of non-NISP decreed water that can be used via NISP facilities, both in volume and in number of years.

4b. Comments on Water Resources Technical Report (WRTR)

WRTR Section: 7.1 Summary of simulated NISP diversions, page 83
Statement: *"NISP would divert water into the primary storage facility (either Glade Reservoir or Cactus Hill Reservoir) through three pathways: …*

- *SPWCP storage exchanges with Timnath Reservoir, Big Windsor Reservoir, and Terry Lake."*

Comment: The use of Terry Lake, Big Windsor Reservoir, and Timnath Reservoir to perform SPWCP exchanges needs to be described in more detail. According to State of Colorado Water Diversion reports, these reservoirs typically fill during the winter months. However, Tables 22, 23, and 24 of the WRTR show that the majority of SPWCP exchanges into Glade Reservoir that are associated with these reservoirs occur primarily in April, May, and June. The impacts related to these exchanges, which could potentially be negative or positive, cannot be evaluated due to a lack of adequate information. An SDEIS must be prepared to analyze and consider these impacts.

5. Cumulative Effects

5a. Comments on DEIS

DEIS Section: 4.28.2.1 Water –Based Actions page, page 4-98 (also WRTR Section 8.1.6 Conclusions regarding HSWMP cumulative effects, page 156)
Statement: *"Based on the currently available information for the HSWMPs, it is not possible to accurately determine the effects to Poudre River flows associated with the transfer and/or exchange of irrigation water from existing ditch headgates to the new proposed HSWMPs storage facilities. As a result of the transfer of nearly 36,000 AF of agricultural water, it is likely that there will be substantial changes in flow on the Poudre River between the points of diversion for the HSWMPs and the current points of diversion."*

Comment: In order to appropriately assess impacts to the stream system, including the cumulative effects of the Halligan-Seaman Water Management Project (HSWMP), there should be more definitive modeling done which includes all reasonably foreseeable actions. The City has recently been working with the Corps of Engineers on the permitting process for the HSWMP. The Corps should incorporate new modeling efforts for the HSWMP into the cumulative effects analysis for NISP. More accurate modeling results are essential to properly define and distribute mitigation requirements between the various projects under consideration in the Poudre Basin. For example, the later part of this statement implies that the HSWMP might deplete the River by up to 36,000 acre feet, since that is the estimated increase in firm yield needed by its participants. Unlike NISP, the HSWMP depletions to the River are not highly correlated with the increased firm yield of the project. Thus, HSWMP will result in much smaller reductions in flow in the affected River stretches since the use of the proposed reservoir enlargements allows additional use of other sources controlled by the HSWMP participants (such as Colorado-Big Thompson (C-BT) units). In addition, much of the converted agricultural water rights can be used by HSWMP participants directly without the reservoir enlargements. The storage of some of these rights allows the water to be used more efficiently, particularly during drought periods. These considerations as evidenced by additional modeling should be discussed in this section in an SDEIS, to more accurately describe the cumulative impacts of NISP given the projected operations of the HSWMP. Failure to use this more accurate approach would deny decision makers critical information and violate both NEPA and Section 404.

DEIS Section: 4.28.3.1 Actions Not Considered Reasonably Foreseeable (Water-Based Activities - Water Rights Acquisition and Transfer), page 4-106
Statement: *"Water rights transfers from agricultural to municipal and industrial uses in the South Platte River and the Cache la Poudre River watersheds are likely. The transfers and timing of the transfers that would take place are impossible to predict, as they would take place in the free market."*

Comment: The viability of the South Platte Water Conservation Project (SPWCP) exchanges relies on the Larimer and Weld and the New Cache companies' water rights

remaining within those two irrigation systems. If enough water in those systems is transferred out of the ditches, this would seriously affect the District's ability to deliver sufficient water to Glade Reservoir. The transfer of shares from these systems to municipal uses should be considered a foreseeable action and an SDEIS must address how water would be delivered from Galeton to Glade in the event that the SPWCP exchanges cannot be implemented due to these transfers. Alternatively, the District must produce contracts and conservation easements to support the position that the SPWCP exchanges will remain a viable means of delivering water to NISP. The NISP project should not be used to facilitate the transfer of water from Poudre River Basin agricultural lands to other basins.

5b. Comments on the Water Resources Technical Report (WRTR)

WRTR Section: 8.1.2.2 Proposed agricultural transfers for storage in Halligan, pages 144 and 146
Statement: *"For example, the combined June flow rate limitation in any single year is 139.09 cfs. Figure 8 shows that average monthly synthesized natural flows at the Canyon Mouth exceed 1,800 cfs in June. This suggests that diversion of Fort Collins' South Side Ditch water at the Halligan and/or Seaman alternate places of storage could have the effect of reducing native flows in the Poudre River reach that includes the Canyon Mouth by over 7.5 percent."*

And;

Statement: *"If the same average annual diversion (14,169 AF) is assumed from the 80CW103 decree, Fort Collins' average annual allotment of PVLC water would be approximately 10,910 AF."*

Comment: These statements overstate the amount of water that the City can move to Halligan (and/or Seaman) Reservoir. These values do not include considerations for ditch losses and the use of these water rights to meet raw water needs within the City. In addition, the City's use of these rights has been and will continue to be made without the Halligan-Seaman Water Management Project (HSWMP) reservoir enlargements. For the water that is stored, the HSWMP will allow these rights to be used more efficiently. These considerations must be addressed in an SDEIS in order to more accurately describe the cumulative effects of the HSWMP.

Part IV - Environmental Impacts

1. Natural Resources General Comments

The City owns 19 Natural Areas comprising 1,423 acres, four parks and over 27 miles of trail associated with the Cache la Poudre River. These facilities have an estimated value of well over $30 million. In addition, the City has made substantial investments in, and bears significant responsibilities for, the planning and management of the Poudre River floodplain and related stormwater matters. In addition, the City's center and Downtown redevelopment efforts are built upon a healthy and sound Poudre River flowing through the heart of Fort Collins. Thus, the City has a substantial interest in the environmental consequences of the proposed action (*See* Table at the end of this Section IV.1 and Table in Section V.1a of these Comments).

Both the DEIS and Vegetation Technical Report acknowledge certain riparian areas to be sensitive through Fort Collins. (Figure 3-14 of the DEIS lists several of Fort Collins' Natural Areas as "Sensitive Riparian Areas along the Poudre River. These include: #3 Butterfly Woods, #4 North Shield Pond, Magpie Meander, McMurry, Salyer, Lee Martinez, Rivers Edge; #5 Williams, Springer; and #6 Cattail Chorus and Riverbend Ponds). These areas were acquired by the City to protect their ecological, recreational, social, aesthetic and economic values in perpetuity for the benefit of the citizens of Fort Collins. For these reasons, these areas qualify for review and protection under Sections 230.40, 230.51, 230.52 and 230.54 of the Section 404(b)(1) Guidelines. The riparian corridor provides ecological services such as flood control, river bank stability, filtration of nutrients and contaminants from agricultural and urban runoff, and critical wildlife habitat within a semi-arid landscape.

Under Clean Water Act Section 404(b), the potential adverse impacts to City Natural Areas must be carefully evaluated to ensure that the integrity of the natural values and "ecological services" of these areas are maintained or improved. *See* 73 Fed. Reg. 19,594 (April 10, 2008). *See e.g.*, Sections 230.40, 230.51, 230.52 and 230.54 of the Section 404(b)(1) Guidelines. The DEIS fails to fully analyze the adverse effects to the natural environment of the Poudre River, and the related impacts to City Natural Areas and other facilities in the vicinity of the River.

The Corps must evaluate and address the adverse impacts from the substantial reductions in flow from NISP and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. This must be done in an SDEIS, Revised Section 404(b)(1) Analysis and subsequent documents.

It is important to note that three Natural Areas (McMurry Natural Area, Cattail Chorus Natural Area, and Running Deer Natural Area), are encumbered by legally-binding conservation easements held by Legacy Land Trust for the State Board of the Great Outdoors Colorado Trust Fund. These legally-binding documents require the City of Fort Collins "*to prevent the significant impairment or interference with conservation values*" which include natural habitat, open space and scenic values of these properties. The City

is legally bound to the citizens and to the State of Colorado to preserve and protect the conservation values of these properties.

With respect to mitigation, the adaptive management approach suggested in the DEIS is inadequate. As proposed in the DEIS, the adaptive management approach generally results in segmentation of the review and analysis of the impacts from NISP, rather than a meaningful and recognizable mitigation strategy. An adaptive management program must first be based on a detailed mitigation plan.

Development of a detailed mitigation plan would need to fully involve the City and other stakeholders and should follow the process developed by The Nature Conservancy and the Army Corps of Engineers and outlined in Richter et al. (2006) and would include and address the following:

- A series of workshops attended by stakeholders to determine an environmental flow plan similar to that described by Richter et al. (2006). An environmental flow plan should be pursued that is based on the best available science developed by river scientists, water managers, and other important stakeholders.
- The magnitude, frequency and duration of flows required for maintaining each specific element of river health should be determined. The key elements include (but are not limited to); river morphology and sediment transport, water quality, fisheries and aquatic biota, recharge of alluvial water table, overbank flooding of specific riparian areas.
- A commitment with binding, enforceable assurances from the Corps and project proponent on the long-term funding, monitoring, and maintenance to meet desired outcomes.
- A commitment to maintain recreation flows as related to the city's substantial recreation and economic interests.

Finally, although each of the mitigation measures proposed (including management of in-channel and riparian vegetation, installation of in-stream structures to control sediment movement, and flow regulation/exchanges, etc.) may be useful and promote desired effects, they will not reduce the impacts of the proposed project to the level of non-significance. The mitigation measures are localized, whereas the potential impacts from the proposed action are systemic. To further reduce the annual peak flows that structure and maintain all aspects of the river system implicates several Section 404(b)(1) Guidelines criteria that have not been addressed in the DEIS. The City is not aware of any way to reduce this to a level of non-significance or to satisfy Section 404(b)(1) based on the current record.

City of Fort Collins Natural Areas along the Poudre River.

Property	Site Acres	Total Cost	Year of purchase	Management Purpose	Miles of Trail	Recreational Uses	Impact by NISP
Arapaho Bend	278	$ 1,601,240	1995	Natural area	2	walk, wildlife, bike, equestrian, dogs, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
Butterfly Woods	24	$ 191,208	1996	Natural area	0.4	walk, wildlife, bike, equestrain, dogs, handicap accessible	Fishing, boating, aesthetics, possible wildlife impacts
Cattail Chorus	40	$ 589,901	1997	Natural area	0.25	walk, wildlife, bike, dogs, handicap accessible	Fishing, boating, aesthetics, possible wildlife impacts
Cottonwood Hollow	93	$ 255,241	1995	Natural area	0.4	walk, wildlife viewing	Fishing, boating, aesthetics, possible wildlife impacts
Gustav Swanson	12	$ 18,735	1955	Natural area	0.3	walk, wildlife, bike, dogs, handicap accessible, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
Kingfisher Point	134	$ 1,214,691	1997	Natural area	0.8	walk, wildlife, bike, equestrian, dogs, handicap accessible, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
Magpie Meander	11	$ 62,878	1995	Natural area	0.2	walk, wildlife, dogs, handicap accessible, fishing	Fishing, boating, aesthetics, possible wildlife impacts
McMurry	45	$ 249,905	1998	Natural area	1.5	walk, wildlife, bike, equestrian, dogs, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
North Shields Pond	10	$ -	1962	Natural area	0.6	walk, wildlife, bike, equestrian, dogs, handicap accessible, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
Nix	34	$ 762,125	1979	Natural area	0.3	walk, wildlife, bike, equestrain, dogs, handicap accessible	Fishing, boating, aesthetics, possible wildlife impacts
Prospect Ponds	25	$ -	1974	Stormwater / Natural area	1.3	walk, wildlife, bike, equestrian, dogs, handicap accessible, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
Riverbend Ponds	223	$ 259,861	1977	Natural area	4	walk, wildlife, bike, equestrian, dogs, handicap accessible, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
River's Edge	8	$ 31,810	1994	Natural area	0.1	walk, wildlife, bike, equestiran, dogs	Fishing, boating, aesthetics, possible wildlife impacts
Running Deer	370	$ 2,850,449	1998	Natural area	2.4	walk, wildlife, handicap accessible	Fishing, boating, aesthetics, possible wildlife impacts
Salyer	24	$ -	1985	Natural area	0.6	walk, wildlife, bike, equestrian, dogs, fishing	Fishing, boating, aesthetics, possible wildlife impacts
Springer	24	$ 10	1990	Natural area	0.5	walk, wildlife, bike, equestrian, dogs, fishing	Fishing, boating, aesthetics, possible wildlife impacts
Sterling	44	$ 1	2007	Natural area	1	walk, wildlife, bike, equestrian, dogs, fishing, boating	Fishing, boating, aesthetics, possible wildlife impacts
Udall	25	$ 335,592	1994	Stormwater/ Natural area	0	not open to public	Fishing, boating, aesthetics, possible wildlife impacts
Williams	1	$ -	1990	Natural area	0.1	walk, wildlife, bike, equestrian, dogs, handicap accessible	Fishing, boating, aesthetics, possible wildlife impacts

2. River Morphology

2a. General Comments

The impacts to stream morphology are identified in the DEIS as:

- channel narrowing
- greater sediment deposition and less sediment flushing
- vegetation encroachment into the channel
- increase in size of in-channel islands
- flow obstruction and flooding
- reducing scouring and channel rejuvenation
- bank erosion

Among the shortcomings of the DEIS geomorphic analysis is a lack of any serious discussion regarding the potential for decreased flood conveyance capacity and increased flood depths associated with channel aggradation, narrowing, and vegetation encroachment in the City of Fort Collins segment. Although Alternative 2 is very likely to increase vegetation encroachment and reduce channel conveyance capacity in the absence of periodic channel maintenance flows, it would not reduce the magnitude of the most extreme flow events delivered to the Fort Collins river segment (e.g., exceedance p = 0.01-0.02 in the annual maximum series). This is a point that must be addressed with regard to public safety and as well as potential costs to the City.

Additional impacts not specifically discussed in the DEIS include

1. Fining of bed sediment and lack of scouring of coarse, immobile sediment;
2. loss of channel complexity;
3. Potential for a threshold in-channel response to altered flows.

At the heart of these three additional impacts is the central role of seasonal snowmelt floods in structuring and maintaining the type of cobble- to boulder-bed, pool-riffle channels represented by the Poudre River between the canyon mouth and Interstate 25. This portion of the Poudre is subject to rainfall-generated flash floods that generate tremendous hydraulic forces and strongly influence channel planform, bedforms, and the diversity of aquatic and riparian habitat. These storms have a recurrence interval of decades to centuries (Shroba et al., 1979; Jarrett, 1989; Grimm et al., 1995). Although they recur infrequently with respect to the lifespan of most aquatic and riparian organisms, the very large rainfall floods set the large-scale physical template of the river system (Shroba et al., 1979), as explained in the DEIS.

In addition to potential decreased flood conveyance and increased flood depths, sediment deposition can change the size distribution of bed sediment. Reduced flows can result in a shift toward finer grained bed sediment that can alter periphyton and macroinvertebrate communities and spawning habitat for fish. Reduced flows can also fail to mobilize sand and gravel size sediment. Under larger, more natural snowmelt peak flows, sand and gravel in transport scours or abrades periphyton from larger, relatively stable cobbles and boulders. The absence of this annual scouring can change periphyton and macroinvertebrate communities (Bunn and Arthington, 2002).

Working on a portion of the Poudre River above Boxelder Creek and just downstream from Fort Collins, Milhous (2007) identified a threshold discharge of 2,050 cfs as necessary to flush sand and finer sediment from the streambed. While this study did not measure or model the duration required for 2,050 cubic feet per second (cfs) to flush sand and sediment, a span of seven days has been estimated by the author of the study (Milhous, 2008). Under the present conditions of regulated flow on the Poudre River, such flushing has occurred during 12 of the past 32 years, with no flow reaching this threshold during the past 7 years (Milhous, 2007). The changes in flow along this portion of the Poudre that are proposed as part of NISP would further reduce the frequency and magnitude of flows capable of flushing sand and fine sediment from the streambed. The frequency of flows above 2,050 cfs under NISP conditions is not known since stream stage was modeled at a monthly time-step. The Spells analysis developed in the River Morphology and Sediment Transport Technical Report provides some daily flow data, however, the results do not indicate the frequency of flows at 2,050 cfs.

The loss of channel complexity refers to reduced physical diversity in the form of bedform sequences (e.g., pools and riffles), secondary or overflow channels, and irregularities in the channel margin that typically result in enhanced age and species diversity of riparian vegetation (Poff et al., 1997). Annual flood peaks of varying magnitude, at least some of which are capable of mobilizing gravel- to cobble-size material, are critical to maintaining channel complexity (Stanford et al., 1996; Poff et al., 1997; Hohensinner et al., 2004). When this complexity is reduced, age and species diversity of aquatic and riparian communities declines (Poff et al., 1997; Galat and Lipkin, 2000; Baron et al., 2002; Bunn and Arthington, 2002). Statements such as that on page 4-30 of the DEIS, "… *this reach is well armored and is stable except during very large flood flows,*" although correct, overlook the importance of annual floods that do not necessarily mobilize the coarsest bed sediment but do produce bed scouring and maintain or enhance channel complexity.

Similarly, statements such as those on page 4-32 of the DEIS *("Impacts from NISP would likely be progressive rather than sudden, could occur over decades, and may be small compared to changes that are already occurring"*) and page 5-15 of the DEIS *("… the response of and changes to the Poudre River associated with the action alternatives are anticipated to be less than the historical morphologic changes that have occurred and continue to occur"*) ignore the possibility of non-linear change in the Poudre River in response to reduced flows. Complex systems, including physical and ecological processes in rivers, are inherently non-linear (Stanford et al. 1996; Ward et al., 2001). Numerous investigators have demonstrated that rivers commonly exhibit complex responses to single external changes such as reduced flow or sediment supply (Schumm, 1974; Merritt and Wohl, 2003).

The DEIS makes no mention of the possibility that further reducing the critically important annual snowmelt peak could cause the Poudre River in the study area to cross a threshold and respond in a non-linear manner that would result in much greater loss of channel complexity and physical and ecological function. Although it is appropriate to start with the simplest scenario and assume continued linear change in a river as annual peak flow is progressively reduced, the potential significant adverse impacts that could result from crossing a geomorphic threshold must be addressed in an SDEIS.

Due to the failure to address critical issues regarding sedimentation and river morphology, the DEIS fails to comply with its obligations under both NEPA and the Section 404(b)(1) Guidelines. *See e.g.*, Section 404(b)(1) Guidelines §§ 230.20 (substrate), 230.23 current patterns), 230.24 (normal water fluctuations), and 230.45 (riffle and pool complexes). These issues must be adequately addressed in an SDEIS.

2b. Specific Comments on DEIS

DEIS Section 1.9.1 Key Issues Identified for Analysis in the EIS, page 1-48
Statement: *"This section identifies the significant issues to be addressed in the EIS. During scoping, comments were submitted, then categorized into several specific areas (ERO 2005a). Based on the issues and recommendations identified in the scoping comments, as well as guidance from NEPA, the following general categories of significant issues will be the focus of the EIS:*

1. Surface Water
2. Stream Morphology
3. Water Quality
4. Water Rights
5. Ground Water
6. Geology
7. Soils
8. Vegetation
9. Noxious Weeds
10. Wetlands and Other Waters
11. Riparian Resources
12. Wildlife
13. Fish and Other Aquatic Life
14. Species of Concern
15. Recreation Resources
16. Cultural Resources
17. Aesthetics and Visual Quality
18. Traffic and Transportation
19. Land Use
20. Socioeconomic Resources
21. Hazardous Sites
22. Noise
23. Air Quality
24. Energy

Comment: The deposition of fine sediments as a result of significantly reduced peak flows is cause for concern under any of the action alternatives. The Scoping Report identified sedimentation as a *"major category"* related to comments received. Sedimentation is a major issue for 404(b)(1) analysis, specifically particulate deposition (see Part 230.21(b)) and changes in current patterns and water circulation related to deposition of suspended particulates (Part 230.23). However, sedimentation was not directly called out in the above list of "significant issues" for the DEIS, but rather was incompletely incorporated into other categories, most notably stream morphology, aquatic habitat and vegetation encroachment. Given the importance of sedimentation in scoping and the Guidelines, this topic should have been directly addressed as an independent topic. Regardless, the Section 404(b)(1) Analysis (Appendix D) does not adequately address this issue**.**

DEIS Section 3.4 Stream Morphology, page 3-22
Statement: *"Most of the Poudre River in the study area is slightly entrenched. The Fort Collins, Greeley Channelized and Greeley Downstream reaches have been channelized due to past human activities such as gravel mining and levee construction, which has resulted in entrenchment of the channel. These areas are unstable, continually working toward the reestablishment of functional floodplains inside the confines of a continually widening channel."*

Comment: First, this statement is partly contradicted by the next paragraph on the same page which states that: *"The streambed through the Laporte and Fort Collins reaches is armored and will remain stable during all but large flood events. During large floods, some channel adjustment would be expected and the armor layer could be disturbed or breached in places, resulting in some instability and bank erosion."* Such contradictory statements in the DEIS make it difficult to understand whether this channel is considered stable or unstable.

Second, the statement that the Fort Collins Reach of the River (defined in the DEIS as the reach extending from the Larimer and Weld Canal to the Fort Collins Wastewater Treatment Plant #2) is unstable and that the channel is continuing to widen is unsupported and is based on the unreliable Rosgen methodology for stream classification. These statements are from the Level 1 Classification Results on page 2.14 of the River Morphology and Sediment Transport Technical Report (ACE, 2008) (RMSTTR), which states that: *"The bankfull width was taken from hydraulic models of top width at "bankfull" flow in the Poudre River…This range encompasses values for both stream types "C" and "F". The bias in the range is toward stream type "C"…The difference between type "C" and type "F" channels is essentially the level of entrenchment, which can be difficult to visually discern in marginal channels (i.e., those stream channels that may be transitioning from one stream type to another)…Entrenched type "F" channels are characteristically unstable and continually work towards the re-establishment of functional floodplains inside the confines of a continually widening channel, which eventually results in the re-establishment of a type "C" stream. This appears to be the case along much of the Fort Collins, Greeley Channelized and Greeley Downstream reaches."*

Roper et al. (2008) has shown that there can be considerable variation in determining Rosgen stream types because of major discrepancies in the determination of bankfull depth which can lead to potentially large differences in determination of flood prone width and consequent values of entrenchment. In addition, Rosgen found that "…the Rosgen method can yield nonunique solutions (multiple channel types), with no clear guidance for resolving these situations" and found that "…some assigned stream types did not match the appearance of the evaluated stream." Based on current conditions, this appears to be the case for the Fort Collins Reach. Existing conditions in this reach, which include extensive bank revetment in many areas, stable banks in the unrevetted areas, and confinement through man-made and bedrock controls in other areas, indicate that the River is "locked in place" and is no longer adjusting laterally. Existing conditions also indicate that the River has developed or re-established an inset floodplain in places. This demonstrates that the DEIS has not accurately characterized the Fort Collins Reach, undermining the analyses of stream morphology in the DEIS.

Finally, the classification of the Fort Collins Reach in the DEIS as being unstable and continuing to widen is also based on the Level II Classification Results on page 2.14 of the River Morphology and Sediment Transport Technical Report which states that: *"The "reference reach" approach was not utilized in the Level II effort, as the purpose is to classify the channel as it currently exists. Channel cross sections were identified that were considered representative of the conditions that were present within each study reach."* However, the description for the Fort Collins Reach from the RMSTTR, in contrast, states on page 2.21 that: "*The combined effect of the natural transitional location and the range of anthropogenic impacts is a highly variable river character in this reach. Channel geometry varies significantly from station to station as is evidenced by the wide variability in bankfull flow characteristics."* Yet, the DEIS characterizes this highly variable reach with 2 cross sections that are supposed to be "representative" of the reach.

Since the Fort Collins Reach is not accurately characterized by the DEIS, then it must be concluded that the DEIS analyses of the impacts of the project on stream morphology and sediment transport/deposition are flawed and inadequate.

DEIS Section 4.2.1.2 Stream Morphology, page 4-8
Statement: *"From the canyon mouth to Fort Collins, the action alternatives would be expected to increase bed and bank stability, but episodic erosion would still occur in response to large flood events. Some channel contraction would be expected in deposition zones."*

Comment: The DEIS does not accurately portray the severity of the impacts on the stream morphology of the Poudre River through Fort Collins. The DEIS discussion regarding this reach focuses on increased channel stability resulting from reduced stream flow. This same conclusion is found in discussion of the effects of the alternatives by resource, in Section 4.4.2.2, Stream Morphology, Fort Collins Reach (DEIS page 4-30). The DEIS primarily relies on the River Morphology and Sediment Transport Technical

Report (Corps, 2008) (RMSTTR) for this conclusion (e.g. see page 4-14 of the RMSTTR).

However, there are many potential adverse impacts to the channel from the significantly reduced flow that are not properly identified or analyzed in the DEIS. The Biological Assessment provided as Appendix B to the DEIS (BA) correctly identified potential adverse impacts stating *"…potential changes include channel narrowing, greater sediment deposition and less sediment flushing, vegetation encroachment into the channel, increase in the size of the in-channel islands, flow obstruction and bank erosion."* (BA, page 29). These concerns are repeated on page 34 of the BA in a discussion of the Poudre River upstream of Interstate 25.

The presentation of potential impacts in the DEIS is also not consistent with the field observations described in the RMSTTR. On page 2.21 of the RMSTTR, based on field observations, it is concluded that throughout the Fort Collins Reach: *"Deposition of fine sediments and subsequent growth of stabilizing vegetation on the channel margins and bars is a common process…"* Specifically, upstream of Shields they observe that *"Bed material is typically cobbles overlain by a veneer of fine sediment…"* From Shields to College the RMSTTR observes: *"…fine material continues to deposit and supports vegetation on channel margins and mid-channel bars*." Finally, below College RMSTTR observes: *"…deposits of fine material support encroaching vegetation…"*

Adding to the confusion, DEIS Table 4-20 (page 4-120), Summary of Estimated Effects for the Alternatives, seems to highlight the BA conclusions, not the DEIS conclusions. Under item 2, Stream Morphology, Table 4-20 indicates that the impacts of reduced peak season flows include channel narrowing, greater sediment deposition and less sediment flushing, vegetation encroachment, larger in-channel islands, flow obstruction, flooding and bank erosion. Yet DEIS Table 4-1 (page 4-4) states that these *"effects would be greatest below Fort Collins to above Greeley"* even though the greatest impact of the project on average monthly flows (e.g., 71% reduction in May for average year) will be in the Fort Collins Reach (see DEIS Table 4-2, pg. 4-5).

The increased deposition of fine sediments under the action alternatives was also not properly addressed in the Section 404(b)(1) Analysis. The Guidelines require that this issue be addressed. *See* Sections 230.21 and 230.24. The DEIS considers only potential changes in suspended sediment concentrations, and not issues related to particulate deposition (DEIS Appendix D, pgs. D-3 and D-4). The Guidelines also address sediment deposition related to changes in current patterns and water circulation. *See* Section 230.23. However, the Section 404(B)(1) Analysis related to this section of the Guidelines does not include any discussion of sediment deposition issues in the Poudre River (DEIS pgs D-11 to D12).

Finally, the Guidelines require addressing changes to riffle and pool complexes (*see* Section 230.45), and cite loss of value related to sedimentation induced through hydrologic modification that can clog riffle and pool areas and destroy habitats. The Section 404(B)(1) Analysis in the DEIS incorrectly concludes, based on a reference to the

RMSTTR, that the *"Impacts to riffle and pool complexes are expected to be minor"* (DEIS Appendix D, pg. D-19). As discussed throughout this section of the Comments, the overwhelming weight of evidence suggests that there will be significant impacts associated with increased sedimentation from NISP that would have serious impacts on riffle and pool complexes - - diminishing some and eliminating many.

The potential adverse impacts related to increased sedimentation of the channel through Fort Collins, as identified in the BA, are of great concern, and the discrepancy between the BA and the DEIS/RMSTTR regarding the range and severity of potential impacts must be resolved in an SDEIS. A Revised Section 404(B)(1) Analysis must also properly analyze the sediment deposition issue in the Poudre River.

DEIS Section 4.2.1.2 Stream Morphology, page 4-9
Statement: *"The most significant impacts of the action alternatives on stream morphology and sediment transport would be expected to occur between Fort Collins and Greeley. The existing process of channel contraction via sediment deposition and vegetation encroachment would be expected to accelerate."*

Comment: This same conclusion is found in the River Morphology and Sediment Transport Technical Report (Corps, 2008) (RMSTTR) on page 4.14, specifically: *"Through Fort Collins and upstream to the canyon, the Project is expected to increase bed and bank stability…"* However, the analysis completed for the RMSTTR does not support this conclusion. For example, the "Spells Analysis" found that the number of significant overbank flows at two stations in the Fort Collins Reach goes from 4 or 5 under baseline conditions to zero with the project, and concludes that this will influence colonization of vegetation and sediment movement and morphology of the channel (RMSTTR, pg. 4.6). The discussion further points out that the longer time between scouring events and the shorter duration of those events will promote vegetation encroachment. This suggests that the Fort Collins reach will also experience widespread deposition and vegetation encroachment, a finding which is more consistent with the field observations reported on page 2.21 of the RMSTTR.

Similarly, the stream power frequency analysis found that the biggest difference in stream power distribution between baseline and project conditions is actually upstream of Fort Collins in the Laporte Reach. Between 2,800 and 800 cubic feet per second (cfs) there is a 48% reduction in flow energy to do work such as moving bed sediments, eroding banks, cleaning out pools, and controlling vegetation (RMSTTR, pgs. 4.6-4.7). This discussion goes on to say that a similar impact will occur in the Fort Collins and Timnath Reaches, but the effect progressively decreases in the downstream direction. The discussion on page 4.8 concludes that the stream power results *"…represent significant decreases in available flow energy, sufficient to lead to noticeable changes in sediment accumulation, reduced scouring of pools, increased vegetative encroachment and decreased bank erosion."* This analysis also seems to suggest more significant changes will occur in the Fort Collins Reach and upstream, rather than the other way round.

The conclusions regarding potential stream morphology impacts in the Fort Collins Reach need to be revised in light of the supporting analysis that was completed. Based on the technical analysis completed for the DEIS, major changes to the channel through Fort Collins (with regard to fine grained sedimentation and vegetation encroachment) would result from the action alternatives. This is a great concern to the City of Fort Collins. As previously discussed, the 404(B)(1) Analysis does not adequately address the sediment deposition issue in the Poudre River under project conditions with regard to Sections 230.20 (substrate), 230.23 current patterns), 230.24 (normal water fluctuations), and 230.45 (riffle and pool complexes). The Corps must evaluate and address the sediment deposition issue and fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section 4.4.2 Stream Morphology – Cache la Poudre River, page 4-30
Statement: *"The overall effect of the action alternatives throughout the study area would be that morphologic and sediment transport processes that depend on moderately high flows would become less dominant."*

Comment: It is well established in the scientific literature that western rivers are not only dependent on large flood events, but are equally dependent on the pulse of annual peak flows for maintaining physical and ecological diversity. The Poudre River is not exceptional in this regard.

Although snowmelt floods are of lower magnitude and generate less hydraulic force per unit area of the channel than rainfall flash floods (Jarrett, 1989), these floods occur every year at differing magnitudes and transport the majority of sediment moved each year, govern the annual pattern of floodplain inundation, deposition and erosion, maintain the bedform sequence and grain-size distribution of the bed sediment, and control the movement of aquatic and riparian organisms and propagules longitudinally and laterally within the river system (Andrews, 1984; Andrews and Erman, 1986; Merritt and Wohl, 2006; Rathburn et al., in press). An assumption underlying much of the DEIS seems to be that, because the River in the study area has coarse bed sediment that is not mobilized annually, infrequent rainfall flash floods not affected by NISP or other flow regulation projects will maintain channel complexity and function. Past changes along the Poudre River in the study area and changes along other, similar river systems, however, indicate that further reducing the annual peak flow will reduce channel complexity and function in a manner that is not adequately recognized by the piecemeal list of expected impacts in the DEIS.

The City has a vested interest in maintaining a healthy and functional river system which retains an open channel capable of transporting flood flows. The process of sediment deposition without the process of sediment flushing through scouring and erosion will lead to vegetation encroachment and subsequent channel constriction. These changes will significantly change the River's function as a conveyor of flood water and result in

flow obstruction, increased flood stages and possibly greater flood damage in the future. The DEIS and 404(b)(1) Analysis are inadequate in their treatment of this issue.

DEIS Section 4.4.2.2 Fort Collins Reach
General Comment: Secondary impacts (modification) from NISP related to channel contraction and reduced capacity could significantly impact how the City manages the Poudre's floodplain and related stormwater protection.

DEIS Section 4.4.2.2 Fort Collins Reach, page 4-30
Statement: *"In these depositional areas such as upstream of Mulberry St, acceleration in channel contraction would be expected and channel capacity reduced."*

Comment: Flood control and stormwater management has been a significant issue since the settlement of Fort Collins. In modern times, the City has experienced a number of flood events (1983, 1997, 1999, etc.) and over the last twenty plus years, the City has adopted a stormwater master plan for the Poudre River (Ayres, 2001) and has invested over $3 million on river stormwater modeling, planning, and construction of flood protection projects. For example, levees to protect the City's Drake Water Reclamation Facility (DWRF) and the residences in the Buckingham neighborhood have been constructed. The river bank has been stabilized in a number of locations through town. Furthermore, the acquisition and relocation of structures from the floodplain have also taken place. With the potential for increased base flood elevations due to sedimentation, these flood protection structures may become inadequate and the properties they are protecting would be at risk of loss and destruction again. The DEIS ignores this vital issue of public safety.

The floodplain along the Poudre River is federally designated by the Federal Emergency Management Agency (FEMA) (Larimer County Flood Insurance Study, 2006). This Flood Insurance Study establishes flood elevations and floodplain limits which are used to administer the floodplain. Channel contraction and vegetation encroachment from NISP would likely have significant adverse effects on base flood elevations (BFEs) and the resulting extent of flood inundations during large recurrence interval floods such as, the 100- and 500-year flood events. Reduced channel conveyance in the Poudre River would likely increase BFEs through the City. In turn, this would widen the limits of the floodplain and potentially add structures and properties into the floodplain and /or floodway that were not previously at risk of flooding. Addition of any new structures or properties to the floodplain would deviate from the City's goal of promoting the public health, safety and general welfare by minimizing future public and private flood losses. Flood risks could affect property values and business relocations, and, therefore, tax revenues. As remapping of the floodplain occurs, additional properties included in the floodplain by FEMA will be subject to the City's floodplain regulations and the mandatory flood insurance purchase requirements of the National Flood Insurance Program. The DEIS does not adequately address these impacts, or the related costs or cumulative adverse impacts to the City.

If the capacity of the Poudre River channel to convey floodwater is materially reduced, new river modeling, planning and prevention measures would need to be put in place to ensure the safety of the citizens of Fort Collins. Unless addressed in the DEIS, subsequent costs of designing, constructing and maintaining additional flood protection facilities or modifying existing structures would be borne by the citizens of Fort Collins. Additional multi-million dollar investments may be necessary. The DEIS does not adequately address these potential cumulative adverse impacts and the related costs to the City of Fort Collins and its Stormwater Utility rate payers, and is particularly deficient in meeting the criteria of Section 230.10(c)(1) and Section 230.11(b) promulgated under Section 404(b)(1).

DEIS Section 4.4.2.5 Summary of Effects to the Cache la Poudre River, page 4-31
Statement: *"Some channel contraction would be expected in depositional zones. The most significant impacts of the action alternatives on stream morphology and sediment transport would be expected to occur between Fort Collins and Greeley. The existing process of channel contraction via sediment deposition and vegetation encroachment would be expected to accelerate."*

Comment: This statement continues the DEIS premise that sediment deposition impacts through Fort Collins will be relatively insignificant. As discussed above, NISP will substantially reduce both river flows and associated channel flow velocities needed to maintain an open channel. Because of these diminished flows and flow velocities, deposition of fine sediments within the gravel and cobble bed of the Poudre River is likely to occur. A resulting cascade of adverse effects could follow, including increased vegetation encroachment into the channel causing the channel to narrow and constrict flows under normal conditions and subsequently obstruct flows under higher flow (flood) conditions.

The DEIS does not accurately define the severity or potential cumulative adverse impacts of fine sediment deposition impacts on the Poudre River through Fort Collins, nor does the Section 404(b)(1) Analysis adequately address the indirect impacts with regard to Section 230.11(b), Section 230.24(b), and Section 230.45(b). Instead, the DEIS concludes that the action alternatives would generally increase channel stability (see DEIS pg. 4-8 as discussed above). This conclusion contradicts the Biological Assessment (BA), which as part of the DEIS, correctly identified potential adverse impacts resulting from large flow reductions during spring runoff in wet and average years. The BA states: *"…potential changes include channel narrowing, greater sediment deposition and less sediment flushing, vegetation encroachment into the channel, increase in the size of the in-channel islands, flow obstruction and bank erosion…"* (Biological Assessment, DEIS Appendix B, page 29). This contradiction between the BA and the DEIS regarding the range and severity of potential impacts of sedimentation on the River through Fort Collins must be resolved in an SDEIS, Revised Section 404(b)(1) Analysis, and revised BA.

DEIS Section 4.4.3 Mitigation
General Comments:
A 25 % to 71% reduction in flows from NISP, as predicted in the DEIS, will result in major adverse impacts to the Poudre River Corridor through Fort Collins. The City's goal is to maintain existing flows and/or provide enhanced flows to support a healthy, functioning, and dynamic river system that is a solid foundation for recreation, pleasing aesthetics, economic benefits and values and diverse wildlife.

The DEIS proposes a few mitigation measures relevant to the Poudre River. While some of the mitigation proposed in the DEIS (including management of in-channel and riparian vegetation, installation of in-stream structures to control sediment movement, and flow regulation/exchanges, etc.) may be useful and promote local desired effects, they are not likely to reduce the impacts of the proposed project to the level of non-significance. In addition, any proposed mitigation strategies that require the installation of structural measures on the River to control sedimentation would have their own direct and indirect impacts on the River which have not been analyzed and must be addressed in an SDEIS.

The few proposed mitigation measures are localized, whereas the proposed alternative is systemic. The City has serious concerns about the proposed mitigation because restoration efforts that "target small reaches through artificial measures are very costly, may require perpetual effort, and often fail" (Rood et al, 2003b). The "adaptive management" proposal is fundamentally flawed as the assessment of the current resource condition is inadequate as is the assessment of environmental consequences associated with the proposed alternative. The Corps must evaluate and address the sedimentation impacts to the River and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

Any substantial reduction in future flows from present conditions will functionally eliminate the existing biological values of the Poudre River system. Spring flow reductions of 25% to 71% are expected to have severe impacts. The following excerpt from a feature article in *Environmental Management* emphasizes the importance of the flow regime to river ecosystems:

> "*Physical processes in streams and rivers largely are driven by the magnitude, intensity, duration, and frequency of water discharge in combination with the catchments lithology and streamside vegetation. Additionally, flow regularity as well as variations in amplitude, frequency, duration, base flow, and rate of change, is also ecologically significant…* ***These characteristics provide the template for the ecological processes and are the underpinning of every major theoretical and conceptual advance made about the ecology of rivers in the last three decades.*"** (Naiman et al., 2002) (emphasis added).

A suite of "overview" papers in the scientific literature have been written in the last decade to advance the science of river management, protection, mitigation, and restoration. The following technical publications written by several of the world's

leading river scientists should be considered in evaluating and addressing these river impacts in an SDEIS and Revised 404(b)(1) Analysis:

- Legitimizing Fluvial Ecosystem As Users of Water: An Overview (Naiman et al, 2002)
- The Natural Flow Regime; A Paradigm for River Conservation and Restoration (Poff et al., 1997)
- Meeting Ecological and Societal Needs for Freshwater (Baron et al., 2002)
- Entering an Area of Water Scarcity: The Challenges Ahead (Postel 2000)
- Process-Based Ecogical River Restoration: Visualizing Three-Dimensional Connectivity and Dynamic Vectors to Recover Lost Linkages (Kondolf et al., 2006)
- Ecology, Planning, and River Management in the United States: Some Historical Reflections (Reuss 2005)
- River Flows and Water Wars? Emerging Science for Environmental Decision-Making (Poff et al., 2003)
- Landscapes to Riverscapes: Bridging the Gap Between Research and Conservation of Stream Fishes (Fausch et al., 2002)

The evaluation of impacts to the River and consideration of ways to address those impacts should not operate in isolation from the world scientific and water resources communities. Currently, there are ongoing research and management efforts in Australia, South Africa, Europe and North America aimed at describing the quantity, quality, and timing of flows necessary for ecological functions to perform while also providing opportunities for human uses (Arthington et al., 1998, Arthington et al., 2000, Commonwealth of Australia; 1996, Bunn 1999; Kingsford, 2000; Pigram, 2000; Humphries and Lake, 2000; Patten et al., 2001). The DEIS ignores state-of-the-art research regarding flow regimes and ecological functions, focusing on a discredited and invalid static approach to river health.

As discussed above in Section IV.1 of these Comments, future river management planning should be made in a collaborative manner following the process developed by The Nature Conservancy and the Corps, and outlined in Richter et al. (2006).

DEIS Section 4.4.3 Mitigation, page 4-31
Statement: "*While it is likely that changes to stream morphology and sediment transport would occur in the Poudre River, there is uncertainty in the extent of change that would occur and in the timing of changes*."

Comment: The degree of uncertainty in the DEIS suggests the review of potential environmental impacts is inadequate.

Changes to the River through Fort Collins both in terms of river dynamics and vegetation response are poorly understood. Part of the statement made above acknowledges this, yet throughout the DEIS conclusions are drawn based on no or little data, and one deeply speculative in favor of the proposed action. The analysis in the DEIS of these changes and related impacts is insufficient. The Corps must evaluate and address the stream morphology and sedimentation impacts to the River and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard.

DEIS Section 4.4.3 Mitigation, page 4-32
Statement: *"Further impacts attributable to the chosen NISP action alternative would be additive to the impacts that already drive change. Impacts from NISP would likely be progressive rather than sudden, could occur over decades, and may be small compared to changes that are already occurring."*

Comment: This statement is highly conjectural. The overall tenor of the DEIS does not acknowledge the real potential for complex and threshold responses in the river system. The geomorphic and ecological literature provides countless examples of such responses. (Merritt and Wohl, 2003, Schumm, 1974, Stanford et al. 1996, Ward et al., 2001). For example, impacts associated with interactions between water quality/quantity are likely to be episodic and occur at time scales less than modeled monthly averages.

Planning and allocation of water resources involves choices among uses, users, and generations. Doing this wisely requires knowing the "bank balance" and having thoughtful projections of future "income" and "expenses.". The typical 20 to 30 year planning horizon of most NEPA studies does not account for the fact that many of the decisions being made have implications that extend well beyond this time horizon. A new reservoir is often assigned a useful life of 100 years and investments made to mitigate impacts to aquatic ecosystems seek to conserve the viability of ecosystem amenities in perpetuity, not just for a few decades (Purkey et al., 2007). In terms of this longer view, the DEIS analyzes the lowest level of possible impact rather than the average or worse-case level of possible impact. This is misleading and insufficient, and must be corrected in an SDEIS.

DEIS Section 4.4.3 Mitigation, page 4-32
Statement: *"These considerations do not lead to a recommendation for an immediate set of mitigation actions. Instead, they suggest that the optimum course of action is a detailed river monitoring program leading to a long-term adaptive management program…The adaptive management program should be considered a toolbox of mitigation measures that could be accessed depending on the monitoring efforts."*

Comment: The integration of adaptive management and NEPA is a relatively new concept that adds the "monitor and adapt" steps to the traditional NEPA "predict-mitigate-implement" model (Aligning National Environmental Policy Act Processes with Environmental Management Systems, CEQ, April 2007). The resulting adaptive management approach in a NEPA context can be described as "predict-mitigate-implement-monitor-adapt." In other words, the basic premise still requires starting with proposed outcomes and mitigation measures, and then by adaptive management adjusting as required in the future. However, the DEIS proposes use of adaptive management that jumps directly to the monitoring step, bypassing the predict-mitigate-implement steps. This violates both NEPA and Clean Water Act requirements to specifically list and describe the mitigation measures that will be implemented to achieve specific goals. *See* Section II.5 and Section II.7 of these Comments. The City of Fort Collins considers the definition of "mitigation" in the CEQ regulations, 40 C.F.R. § 1508.20, to be comprehensive and accurate and incorporates that definition for its references to mitigation throughout these Comments.

The concept of adaptive management, as contemplated in this DEIS, is not sufficient to mitigate potential NISP-related flood damage. The effects of channel contraction and vegetation encroachment must first be fully quantified and corresponding effective mitigation efforts identified in an SDEIS and Revised Section 404(b)(1) analysis. NISP participants should pay all costs for planning, design, construction, and ongoing maintenance of those mitigation efforts.

In addition, a sensitivity analysis should be performed and incorporated into an SDEIS to determine the range of effects the channel constriction will have on channel flood carrying capacity and resulting flood elevations. The results of this study could then proactively be used to determine effective mitigation efforts, if any exist, and their associated costs. The City should be included as an active participant in the development, design, and approval of any sensitivity analysis and any subsequent implementation efforts.

DEIS Section: 5.1.2.2 Enhancement of Streamflows through Fort Collins, page 5-4
Statement: *"To mitigate for impacts to aquatic resources associated with Alternative 2, the District commits to work with CDOW to enhance Poudre River winter flows primarily through Fort Collins for the purpose of enhancing a fishery on this reach of the Poudre River. The primary target reach starts at the Larimer-Weld Canal headgate just west of Shields Street and extends downstream to Mulberry Street, a distance of 3.7 miles."*

Comment: Any mitigation that compensates for flow depletions is of particular interest and concern to the City of Fort Collins. However, it is not possible to evaluate this mitigation proposal without more specific information. The District's commitment to work with DOW to establish a fishery in the river section between the headgate of the Larimer and Weld canal to Mulberry Street needs to be more specific, definite and enforceable to constitute minimization or mitigation under Section 404. There is no information as to the minimum target flow rates and the duration of such flows to which the District will commit to provide for the fishery. A specific plan must be developed and described in an SDEIS that will specify minimum wintertime flows, summertime flows, types of fish these flows will support, where the water will come from and how the District and the Corps will insure that the program be implemented. Without additional detail or commitments, these vague assertions do not suffice to address the serious harms to the aquatic ecosystem in the City.

DEIS Section: 5.1.2.2 Enhancement of Streamflows through Fort Collins, page 5-4
Statement: *"Release flow from Glade Reservoir for recapture at the SPWCP pump station."*

Comment: The District's commitment to release water from Glade Reservoir for recapture in Galeton Reservoir to improve flows through town needs to be more specific to constitute minimization or mitigation under Section 404. There is no information as to the minimum target flow rates and the duration of such flows to which the District will commit to provide for this purpose. A specific plan must be developed and described in an SDEIS that will specify minimum wintertime flows, summertime flows, where the water will come from and how the District and the Corps will insure that the program be implemented. Without additional detail or commitments, these vague assertions do not suffice to address the serious harms to the aquatic ecosystem in the City.

DEIS Section: 5.1.4 Environmental Streamflows, page 5-6
Statement: *"The District has stipulated the Grey Mountain water right to three streamflow requirements on the Poudre River used to benefit fishery, recreation, and other environmental purposes (Table 5-1). The District will curtail its diversions from the Poudre River for NISP when the streamflow requirements for each of the facilities listed in Table 5-1 occur and CDOW (Watson Lake Fish Hatchery) or Fort Collins (boat chute and nature center) places a call on the river for the streamflows."*

Comment: This statement is misleading. The District's commitment to subordinate the Grey Mountain decree to the City's two recreational in-channel diversion water rights (RICDs) and to the Watson Lake diversion does not guarantee minimum streamflows through Fort Collins. The RICDs (which are for flows ranging from 5 to 30 cubic feet per second) and the Watson Lake water rights (which are for flows ranging from 25 to 50 cubic feet per second) only apply to very short segments of the River and are for relatively low flow amounts, and because they are very junior water rights, they do not guarantee minimum streamflows through town for a healthy Poudre River riparian

corridor. A specific plan must be developed and implemented and described in an SDEIS that will specify minimum wintertime flows, summertime flows, where the water will come from and how the District and the Corps will insure that the program be implemented. Without additional detail or commitments, these vague assertions do not suffice to address the serious harms to the aquatic ecosystem in the City.

DEIS Section: 5.1.4 Environmental Streamflows, page 5-6
Statement: *"The District also will curtail its diversions from the Poudre River for NISP when the streamflow requirements for each of the facilities listed in Table 5-1 occur, provided the District can be assured that the passed water will reach the facilities and not be diverted by junior appropriators."*

Comment: The District's commitment to curtail diversions from the Poudre River does not guarantee minimum streamflows through town. A specific plan must be developed and implemented and described in an SDEIS that will specify minimum wintertime flows, summertime flows, where the water will come from and how the District and the Corps will insure that the program be implemented. The District and the Corps need to develop a legally defensible plan, conforming to Colorado water law, to ensure the maintenance of a minimum streamflow through town to protect the viability of the Poudre River riparian ecosystem. Without additional detail or commitments, these vague assertions do not suffice to address the serious harms to the aquatic ecosystem in the City.

DEIS Section: 5.16 Riparian Resources, page 5-7
Statement: *"Riparian resources along reaches of the Poudre River may be affected by reduced streamflows during the growing season."*

Comment: The stream habitat enhancement project (DEIS Section 5.1.2.2) is cited as one of the measures that will provide mitigation, however, that project will enhance winter flows, not flows during the growing season. The proposed plan to periodically curtail diversions during high flows has some promise, but without technical or legal specifics, its value and ability to reduce impacts to a level of non-significance cannot be determined and is insufficient for NEPA and Section 404 purposes. As discussed above, any mitigation that compensates for flow depletions is of great interest to the City of Fort Collins, and mitigation for lost peak flows is particularly significant, but without more information it is not possible to evaluate how this might impact flows through Fort Collins.

DEIS Section: 5.1.6 Riparian Resources, page 5-7
Statement*: "The District will also develop a plan to be approved by the Corps for periodically curtailing diversions from the Poudre River for at least 24 hours during high flows, which could provide the riparian areas with periodic disturbance and inundation. The diversion curtailment plan will be implemented provided the District and Corps can*

be assured that the passed water will flow to at least I-25 and not be diverted by junior appropriators."

Comment: The District's commitment to work with the Corps to develop a plan to periodically curtail diversions from the Poudre River for a minimum of 24 hours during the high flows to provide disturbance and inundation requires more detail. More information is needed about the target flow rates, the timing and the duration of these flows and the target reach over which they will occur. The District and the Corps need to develop a legally defensible and enforceable plan, conforming to Colorado water law, and describe it in an SDEIS to ensure that these flows will not be diverted by junior appropriators. Without additional detail or commitments, these vague assertions do not suffice to address the serious harms to the aquatic ecosystem in the City.

DEIS Section: 5.2.3 Enhance River Flows Through Fort Collins, page 5-8
Statement: *"The District will seek an agreement with the Lake Canal Company to move diversions from the Lake Canal intake…"*

Comment: The proposed addition of 50 cubic feet per second (cfs) to the River for about 6 weeks is inadequate to compensate for lost high flows. While this proposed flow enhancement is offered to mitigate impacts to recreational needs of the City's proposed water craft course, it is not adequate because the water craft course requires minimum flows of 250 cfs. *See* Section V.2 of these Comments. There is no information or analysis in the DEIS as to what the base flows would be during various times of the year to evaluate whether the additional 50 cfs would materially improve the prospects for a water craft course if NISP proceeds. Furthermore, high flows are critical to more than just recreation. Reduced high flows as part of the proposed action will negatively affect stream morphology, water quality, riparian resources, fisheries, and socioeconomic values in the Fort Collins river reach. More than 50 cfs will be required to reduce the impacts to river flows through Fort Collins to a level of non-significance (see comments related to hydrology, morphology, fisheries, vegetation, and wildlife**.**

DEIS Section: 5.2.3 Enhance River Flows through Fort Collins, page 5-8
Statement: *"The District will also explore agreements with other water providers to retime their direct flow rights by temporarily storing water in Glade Reservoir and/or its forebay for release during late July and August. Such agreements would add to the flows of the Poudre River through Fort Collins during the summer."*

Comment: The District's commitment to work with water providers to retime their direct flow rights requires more detail. More information is required to describe how the mitigation would improve the flows above those reported in the DEIS in this section of the River. The District and the Corps must develop a plan and describe it in an SDEIS that illustrates the location and magnitude of the improvements to summertime flows, how these will enhance recreational opportunities, and how the plan will be implemented

and enforced. Without additional detail or commitments, these vague assertions do not suffice to address the serious harms to the aquatic ecosystem in the City.

DEIS Section: 5.2.3 Modify Diversion Structures for Boat Passage, page 5-8
Statement: *"The District will explore the modifications of the…Fort Collins Water Treatment Plant diversion to facilitate boat passage."*

Comment: The Fort Collins water treatment plant diversion is a unique structure that allows direct diversion of Poudre River water while minimizing the amount of organic material (particularly pine needles) and inorganic (sediment) passing into the pipeline. While the City could support the idea of modifying the structure to open up more of the River for boating recreation, it is very concerned about any modifications to a structure that is critical to the water supply for the City. This concern is amplified given the potential for additional pine needle problems as the pine beetle epidemic moves east over the Continental Divide. Before the City would consider any modifications to its structure, extensive studies and investigations would be required, including but not limited to laboratory physical model studies of proposed changes to the structure. While not clearly stated, it must be assumed that any such modifications to the City's structure for the benefit of the NISP project would be paid for entirely by the NISP project. Even then, the City would proceed very cautiously and, should it allow structural modifications, it would require agreements for future remedial action in case the performance of the modified structure is not acceptable. It should also be noted that the DEIS and Section 404(b)(1) Analysis were deficient in that they did not address this issue.

DEIS Section: 5.7 Stream Morphology, page 5-15
Statement: *"Based on an evaluation of historic data (Anderson 2008), the response of and changes to the Poudre River associated with the action alternatives are anticipated to be less than the historical morphologic changes that have occurred and continue to occur. Distinguishing the effects of NISP from current trends in river changes will likely be challenging and most effectively determined through a monitoring and adaptive management program."*

Comment: Aside from a review of a limited number of previous studies, the River Morphology and Sediment Transport Technical Report (Corps, 2008) (RMSTTR) does not provide a comprehensive assessment of the historical geomorphologic changes that have occurred on the Fort Collins Reach of the River. A detailed historic aerial photo and map analysis could have been used to identify and document detailed, long-term changes in planform characteristics for specific segments of the Fort Collins Reach, which could then have been used to qualitatively predict what the potential impacts of the project would be to those segments. Instead, the RMSTTR only examined 1937/1941 and 2005 aerial photography and only compiled and provided limited data on 2005 average sinuosity, meander wavelength, and meander amplitude. The only comment regarding historical changes is provided on page 3.63 of the RMSTTR which states that: "*For example, the review of aerial photography indicated changes in the channel*

alignment and planform at the specific locations identified below…Within the Fort Collins Reach, channel planform changes have occurred at two locations; from Station 209,500 to Station 211,300 and from Station 221,600 to Station 223,600." However, the RMSTTR did not provide any details on what those changes were. A more detailed analysis of historic conditions and changes needs to be included in an SDEIS to identify specific problem areas for conditions under the proposed alternatives and to address related impacts.

DEIS Section: 5.7 Stream Morphology, page 5-15
Statement: *"For any of the action alternatives, the District will develop and initiate a monitoring and adaptive management program…"*

Comment: The District's commitment to develop an adaptive management plan to address the stream morphology impacts requires more detail and does not substitute for adequate analysis of project impacts and a detailed evaluation of how those impacts would be addressed. The Corps must evaluate and address impacts and must fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. Without additional detail or commitments, the vague assertions about possible mitigation do not suffice to address the serious harms to the aquatic ecosystem in the City. *See also* discussion in this Section above related to DEIS Section 4.4.3 (DEIS page 4-32).

DEIS Section: 5.7 Stream Morphology, page 5-15
Statement: *"These mitigation measures may include, but are not limited to… accelerate establishment of channel forming by managing in-channel or riparian vegetation."*

Comment: This statement is confusing. If the proponents intend to accelerate the formation of an inset channel and floodplain based on the potentially flawed Rosgen classification of the river reach (as discussed above) the effort may be counterproductive. Without a firm understanding of the river hydrology (volume, sediment loading, grade, flood timing, etc.) which is the ultimate driver of the channel's physical condition (planform, depth, bank characteristics, etc.), channel modifications become an exercise in river aesthetics when not matched with the existing and future hydrology. While local channel modifications can create habitat, the proposed action is systemic, not localized, and the modified river hydrology is likely insufficient to perpetuate in-channel mitigation efforts.

DEIS Section: 5.7 Stream Morphology, page 5-15
Statement: *"These mitigation measures may include, but are not limited to… check structures or weirs to control the inundation of riparian vegetation."*

Comment: This would only encourage more sediment deposition and all the associated adverse impacts that the City of Fort Collins is concerned about, including channel narrowing, less sediment flushing, vegetation encroachment, larger in-channel islands,

flow obstruction, reduced conveyance and increased risk of flooding, and bank erosion. Also, as previously stated, the proposed mitigation strategies that require the installation of structural measures on the River to control sedimentation would also have direct and indirect impacts to the River that were not addressed in the DEIS Section 404(b)(1) Analysis.

DEIS Section: 5.7 Stream Morphology, page 5-15
Statement: *"These mitigation measures may include, but are not limited to… manage flows to provide flushing in selected river reaches."*

Comment: This is a valuable mitigation strategy, but it cannot be evaluated without more specific technical and legal information about how flows could and would be managed to provide flushing in selected reaches (including what reaches would be selected).

2c. Comments on River Morphology and Sediment Transport Technical Report (RMSTTR)

RMSTTR Section: 3.5.3 SIAM Analysis, page 3.54
Statement: *"The incipient motion analysis indicates that the armor layers will not be penetrated in the upper portion of the study reach from Laporte through Timnath for Baseline and Project conditions. In these upper reaches, the size of the bed material that composes the armor layer is large enough to withstand the hydraulic forces that would be necessary to transport the material…*

The results of the incipient motion analysis determined the bed gradation selected for the SIAM analysis. The bed gradations representing the armor layer were applied to SIAM in reaches where the armor layer was determined to be unbreakable for the flows represented by the annual flow duration curve…"

Comment: Bed mobility calculations are used to assess potential project impacts and to justify simplifying assumptions of sediment transport modeling. The general message seems to be that the armored riverbed through Fort Collins is already immobile except at the most extreme flows (DEIS pg. 3-22). Two implications the DEIS thereby relies on are that: 1) reductions in peak flows by the project would have a minimal effect with regard to scour processes that prevent vegetation encroachment; and 2) deposition of subsurface bed sediments released by armor breaching need not be accounted for in SIAM modeling aimed at assessing deposition potential.

Tables 3.13 and 3.14 (pg. 3.53) are interpreted by the authors to suggest that mean values of shear stress (averaged across entire cross-sections) estimated from hydraulic modeling are insufficient to mobilize median sizes of the existing surface armor layer. This interpretation is flawed. First, cross-section average values of shear stress were averaged throughout the entire segment. Solely using these values to make conclusions about pre-

and post-project bed mobility essentially ignores spatial heterogeneity in shear stress distributions at the cross-section scale and within the entire segment. The maximum values of shear stress reported are clearly sufficient to mobilize armor material. The highest values also occur with a greater frequency and *duration* in the baseline flow series.

Second, the analysis is based on critical dimensionless shear stress values averaging approximately 0.047 for most of the grain sizes examined. In the new edition of the ASCE Sedimentation Engineering Manuel, Parker (2008a) recommends a value of 0.03 for the initiation of significant bed mobility. Previous research on gravel bed rivers indicates that a large fraction of the long term sediment load is associated with "marginal" transport at critical shear stress values substantially less than 0.047 (*e.g.*, Andrews and Nankervis, 1995) report a measured value of 0.035 for the Poudre at Rustic). Indeed, if the simple average stress values for Fort Collins Reach B1 are reassessed using a critical dimensionless shear stress value of 0.035, one reaches the opposite result, i.e. baseline conditions of 0.037 and project conditions of 0.033. As such, the conclusions regarding potential changes in sediment transport and bed mobility should be reconsidered with an accounting of changes in frequencies and durations of flows exceeding incremental values of critical dimensionless shear stress down to 0.03 for the median bed material.

Magnitude-frequency analyses based on stream power and the SIAM model were also used to explore potential changes in sediment transport capacity. Like the incipient motion analysis described above, the analyses are inadequate for assessing pre- vs. post-project changes in sediment transport capacity. First, the magnitude frequency analyses are based on total stream power. Because bedload transport scales with stream power to exponents greater than one (much greater than one at lower transport rates), the pre- and post-project cumulative stream power distributions underestimate actual differences in bedload transport capacity. Second, the bedload transport analyses conducted with SIAM are based on the Meyer-Peter and Mueller (MPM, 1948) bedload relation. This equation was recently recalibrated and corrected by Wong and Parker (2006) and is applicable to high transport rates. Parker (2008b) states: "According to MPM, then, these [gravel] rivers can barely move sediment of the surface median size Ds50 at bankfull flow. Yet most such streams do move this size at bankfull flow, and often in significant quantities. There is nothing intrinsically "wrong" with MPM. In a dimensionless sense, however, the flume data used to define it correspond to the very high end of the transport events that normally occur during floods in alluvial gravel-bed streams. While the relation is important in a historical sense, it is not the best relation to use with gravel-bed streams."

Using this equation in the SIAM analyses basically means there is no transport of particles subjected to dimensionless shear stresses less than 0.047. The assumption described above, namely that there is no release of sediments from beneath the armor layer, also decreases the potential for deposition due to specification of the SIAM model. This is not physically correct. The SIAM analysis correctly indicates increased deposition of relatively fine sediments which can be transported according to the model parameterization.

The analyses described above do not provide what is needed to assess potential changes in bed mobility and bedload transport:

- Use of a range of critical shear stress values ranging from 0.03-0.047 to assess the frequency and duration of bed mobility, pre- and post-project, with better accounting for spatial variability;
- Use of a hydraulic parameter that actually scales with sediment transport capacity in the magnitude-frequency analyses; and
- Use of a continuous bedload function (e.g., Parker, Wilcock and Kenworthy, or Wilcock and Crowe as opposed to the outdated MPM threshold approach) to account for differences in cumulative sediment transport capacity and aggradation potential.

Reliable estimates of bed mobility and scouring potential are integral to predicting encroachment of vegetation, channel narrowing, and associated increases in flow resistance that diminish channel capacity during flood events. Bed scouring is also linked to preventing proliferation of algae and other periphyton along with other factors such as temperature and light. Bed mobility is also associated with reduced substrate embeddedness and rejuvenation of benthic habitat. Given that the SIAM analysis based on MPM probably underestimates deposition potential, the potential effects of substrate changes on benthic communities are more difficult to evaluate. A more robust scour analysis is an essential step toward assessing these potential responses and impacts.

RMSTTR Section: 4.1.8. Sediment Transport Analysis, page 4.9
Statement: *"In summary, the results of sediment transport analysis indicate that it is reasonable to represent the Laporte and Fort Collins reaches as transport reaches. That is, all sediment arriving in the reach is transported through the reach…"*

Comment: The sediment transport analysis in the RMSTTR was not adequate to address the potential deposition of fine sediments in the Poudre River channel through Fort Collins that could occur given the large flow reductions projected under the action alternatives. The sediment transport analysis was based on SIAM using a maximum wash load size of 8 mm in the upper Fort Collins Reach, and 4 mm in the lower Fort Collins Reach. As described on page 3.55, *"SIAM will pass all material equal to and smaller than the selected maximum grain size…"* Sediment particles in the 4-8 mm range are classified as medium gravels, and so the potential deposition of sand-sized materials, which is already occurring under existing conditions and embedding cobble-sized particles in the channel bottom, was ignored by this analysis. This is a significant oversight given that one of the most significant adverse impacts expected from the flow reductions that will occur under project conditions is deposition of fine sediments throughout the Fort Collins reach.

Additionally, even though the RMSTTR states that the Fort Collins Reach is a transport reach, Table 3.16 on page 3.56 indicates that the average annual sediment balance for

Reach B1 under Project conditions is more than 2.5 times greater than under Baseline conditions; in other words it would be significantly aggradational under Project conditions. Although the volume is not as large as downstream reaches, it is significant locally. Over time this could be problematic with regard to increased spawning gravel embeddedness, bed and bar siltation, and vegetation encroachment. For example, a quick calculation of what this balance would produce in terms of average annual sedimentation along the Fort Collins Reach B1 under Project conditions is about 0.6 inches per year or about 6 inches in 10 years, based on the SIAM results. This volume would likely be significantly greater if grain sizes used in the SIAM analysis accurately reflected the fine grained nature of current deposits along the river bed.

The hydrologic analysis conducted for the DEIS indicates that the average monthly streamflow at the Lincoln Avenue Stream Gage for the District's Proposed Action could be reduced by as much as 74.5% for an average year (DEIS Appendix A). Given this significant reduction in flows for May through August, this could have a significant impact on sediment distribution in the River, especially if major tributary sources of sediment remain uncontrolled. The RMSTTR does not adequately address this potential reduction in flow and the direct impacts on sediment transport nor does it adequately address the sources and potential contributions of tributary sources of sediment. Instead of conducting the SIAM analysis for a Wet, Average, and Dry year, the analysis is conducted using the mean annual hydrograph for the period of record. Conducting the SIAM analysis for a Wet, Average, and Dry year using more representative grain sizes for the Fort Collins Reach would yield more accurate and useful results.

RMSTTR Section: 4.2.3 Laporte and Fort Collins Reaches, page 4.12
Statement: *"…However, there are areas where the moderately high flows are contributing to channel maintenance by scouring of fine material and limiting vegetation encroachment. In these depositional areas (such as upstream of Mulberry Street), accelerated channel contraction can be expected. The sediment modeling supports this contention, indicating that small volumes of fine and medium gravels deposit in this reach and this trend is slightly increased with the Project.*

If deposition and vegetation lead to a reduction in channel capacity, this may have an impact on flood profiles and could lead to isolated instances of accelerated bank erosion during floods. This is already a trend in some areas, suggesting an active monitoring and adaptive management approach is required.

Bank erosion occurs sporadically within the reach. Other than the situation described above, changes due to the Project are more likely to contribute to bank stability than bank erosion. Elsewhere, minor vegetation encroachment would continue on channel margins and bars and may be slightly accelerated by the Project."

And;

RMSTTR Section: 4.2.3 Laporte and Fort Collins Reaches, page 4.14

Statement: *"The vegetation-sedimentation process is threshold dependent and it is not realistic to make quantitative predictions about this change.* ***It is reasonable, however, to predict that the rate of channel contraction will increase between Fort Collins and Greeley as a result of the Project.*** *The magnitude of this increase cannot be quantified but the increase could vary from minor to moderate in its impact on the river system. Reliable quantification of existing and future rate of channel contraction will require extensive monitoring."*

Comment: Although the authors of the RMSTTR assert that vegetation encroachment will be "minor" through the Fort Collins segment, no sound factual basis is provided for this conclusion. If the response is "threshold dependent", "accelerated," and complex, what is the basis for predicting it will be "minor"? In addition, the SIAM analysis is also the basis of the conclusion that deposition below canyon "is expected to be undetectable." No reference is made to time scale or degree of precision necessary for detection. The rationales for these conclusions should be reassessed and clearly articulated in an SDEIS based on corrections to the bed mobility and sediment transport analyses described above.

3. Riparian Vegetation and Wetlands

3a. General comments

The following comments focus specifically on impacts to the Poudre River riparian corridor through the City of Fort Collins between Overland Trail to Interstate 25. In general, the City has significant concerns with the information presented in the Vegetation Technical Report that lead to the conclusion presented in Section 4.2 and 4.12 of the DEIS. The conclusions presented in the Vegetation Technical Report (VTR) seem to rely on the judgment of the authors rather than data collection, literature review, and analysis.

Analysis related to vegetation and wetlands along the Poudre River is deficient in its review of the scientific literature and accepted principles of western river ecology as they relate to anthropogenic modification of flow regime. In one instance an analysis in the VTR uses an incorrect numerical data set which led to false conclusions (see comments regarding Section 6.2.5 in Section IV.4c of these Comments, below**)**. Similarly, analysis of existing conditions failed to identify jurisdictional wetlands along the riparian corridor through Fort Collins and evaluate the environmental consequences of the proposed action on those wetlands. Other specific concerns include:

- Failure to evaluate wetland resources according to Section 404(b)(1) guidelines;
- Use of single snapshot field observations to draw important conclusions related to surface and groundwater hydrology;
- Use of a monthly hydrologic time step in the modeling effort that fails to address short term changes (day to day) critical to vegetation and related limitations;

- Failure to assess impacts to the entire stretch of the River through Fort Collins and focusing on presumed "sensitive areas;"
- Failure to address anticipated vegetation encroachment into the channel (terrestrialization), the likelihood of non-native plant encroachment and its ecological and economical consequences;
- Failure to use groundwater well monitoring through several seasons and years to support significant assumptions on groundwater movement within a highly complex watershed;
- Failure to consider potential sub-lethal physiological and morphological stress to cottonwoods; and
- Failure to identify a long term effect as an "environmental consequence".

Conflicting conclusions presented in the DEIS regarding impacts to riparian vegetation represent a serious shortcoming. In several locations the DEIS states there will be adverse impacts to riparian vegetation. Yet the VTR and corresponding sections in the DEIS (4.2 and 4.12) state… *the proposed action will cause no loss of riparian/wetland vegetation.*

Because ecological systems work as a set of many interdependent components and interactions, the impacts to riparian vegetation are fundamental to terrestrial wildlife, invertebrate communities, water quality and aquatic wildlife. Potential changes to the riparian corridor must also be evaluated in the context of human services such as recreation, aesthetics, nutrient filtration, stormwater management, and economic development relative to downtown businesses.

Because of these significant issues highlighted above and described in detail below, a complete understanding or review of the proposed action and its consequences is not possible at this time. Thus, an SDEIS is needed to fully address the issues highlighted in this and other sections of these Comments.

3b. Specific comments on the DEIS

DEIS Section: 4.2.1.3 Wetlands, page 4-9
Statement: *"Reductions in streamflow may affect wetlands directly linked and supported by flows in the Poudre River."*

And;

Section 5.6 page 31 (Vegetation Technical Report)
Statement: "*Palustrine Persistent Emergent and Palustrine Scrub-Shrub Wetlands have established adjacent to the active channel and in depressions in the floodplain."*

Comment: The DEIS fails to identify jurisdictional wetlands along the Poudre River through Fort Collins. According to 404(b) Guidelines, it is necessary to delineate the jurisdictional wetlands along the Poudre River. Such secondary or indirect impacts of the project are clearly within the range of impacts that must be evaluated, and in this case an SDEIS and Revised 404(b)(1) Analysis are needed to do so. *See* Part II of these Comments. Use of the CDOW riparian maps coupled with single-day, field observations is insufficient to adequately evaluate the impacts of the proposed action on wetlands and wildlife habitat along the Poudre River. Additional investigation is required by the Clean Water Act:

> *The degradation or destruction of special aquatic sites,… is considered to be among the most severe environmental impacts covered by these Guidelines. The guiding principle should be that degradation or destruction of special aquatic sites may represent an irreversible loss of valuable aquatic resources.* Section 230.1(d) (Emphasis added).

Furthermore, the environmental consequences should be evaluated by treating Natural Areas as sanctuaries, wildlife refuges and parks (see Sections 230.40, 230.54 of the 404(b) Guidelines). *See also* Section II.2 of these Comments. The potential damage to human use characteristics in this habitat must also be evaluated for compliance and consistency with Section 404(b)(1) Guidelines Sections 230.51, 230.52, and 230.53.

Finally, the analysis presented in the Vegetation Technical Report (VTR) does not provide "*appropriate factual determinations, evaluations, and tests on the physical…*" for the riparian resource, in violation of Section 230.11 of the Section 404(b)(1) Guidelines.

> *For actions subject to NEPA the analysis of the alternatives… will in most cases provide the information for the evaluation of alternatives under these Guidelines. On occasion, these NEPA document…may not have considered the alternatives in sufficient detail to respond to the requirements of these Guidelines... In the latter case, it may be necessary to supplement these NEPA documents with additional information.* Section 230.10 (4)

Without proper delineation and biological evaluation of the riparian corridor it is not possible to properly evaluate and address the impacts to the riparian corridor, as required under the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments.

DEIS Section: 4.2.1.4 Riparian Resources, page 4-9
Statement: *"The reductions in stream flows on the Poudre River associated with the action alternatives are not anticipated to cause a loss of riparian and/or wetland vegetation…because this vegetation appears to be supported by the lower more frequently occurring flows."*

Comment: This is the major conclusion addressing impacts to riparian vegetation, yet it is unsupported by real data, case studies, or relevant scientific literature. Peer-reviewed scientific studies have concluded repeatedly that altered flow regimes can cause significant adverse impacts to riparian vegetation (Reily and Johnson, 1982, Rood and Mahoney, 1990, Tyree et al., 1995, Rood et al., 1995, Poff et al., 1997, Kranjcec et al., 1998, Lesica and Miles, 1999, Jansson et al., 2000, Nilsson and Berggren, 2000, Obedinski et al., 2001, Nilsson and Svedmark, 2002, Rood et al., 2003a, Rood et al., 2003b, Friedman et al., 2005, Stromberg et al., 2007). The conclusion that none of the action alternatives will impact the riparian vegetation is inconsistent with current science based on field data, peer-reviewed analysis, and valid ecological modeling, and is not based upon any credible, scientific or engineering evidence. *See* related comments in Section IV. 2.12 regarding Vegetation Technical Report. *See also* additional comments on this subject in comments on DEIS Sections 4.12.4 and 4.13, in these Comments, below.

DEIS Section: 4.2.1.4 Riparian Resources, page 4-9
Statement: "*The reductions in stream flows on the Poudre River associated with the action alternatives are not anticipated to cause a loss of riparian and/or wetland vegetation…because this vegetation appears to be supported by the lower more frequently occurring flows."*

Comment: The following four statements show the significant inconsistency within the DEIS and supporting documents to the statement immediately above.

Section: 7.2.1 page 65 (Wildlife Technical Report)
Statement: *"The action alternatives would likely result in changes to and losses of riparian and wetland vegetation, especially herbaceous vegetation, in sensitive riparian areas along the Poudre River corridor. Many species of birds, mammals, reptiles, and amphibians dependent on these habitats would in turn be affected by these changes."*

DEIS Section: 4.2.1.1 Changes to Poudre River Flows, page 4-6
Statement: *"Flow reductions are likely to have significant localized effects on water based recreation and recreation values, riparian resources, stream morphology."*

Section: 4.1.5 page 4.5 (River Morphology Report)
Statement: "The spells analysis further elaborates the likely impact of the project ….with a particular significance to geomorphology or colonization and survival of vegetation…"

Technical Memorandum: NISP Visual Impacts to Recreation Activities
Statement: *"Reduced water flows in the river would decrease the area of riparian vegetation communities and surface water."*

Comment: It is difficult, if not impossible, to evaluate the DEIS in this regard, because the document contains contradictory conclusions such as these, and provides inadequate support for any of them. The four preceding excerpts are representative of various contradictory conclusions within the DEIS regarding impacts to riparian vegetation.

DEIS Section: 4.2.1.4 Riparian Resources, page 4-9
Statement: *"However, a reduction in the infrequently occurring overbank flows in the reach above I-25 may affect the periodic disturbance of the riparian zone that can aid in creating new habitat for riparian vegetation establishment and rejuvenation of the riparian zone. Without this disturbance and a substantial reduction in the frequency of this occurrence of overbank flows, it is likely that the woody riparian vegetation will become increasingly decadent. This would be a slow process that would be difficult to separate from current trends in riparian vegetation along the Poudre River."*

Comment: Although in the previous paragraphs the DEIS anticipated no loss of riparian and/or wetland vegetation, the authors follow by predicting an effect on the long-term capacity for regeneration. The statements are in direct conflict with each other because a long-term effect is an effect. In sum, anticipated changes in vegetation under the proposed action are distinguishable from current conditions and an SDEIS must identify and analyze this long-term effect.

DEIS Section: 4.2.1.4 Riparian Resources, page 4-9
Statement: *"…reduced high flows on the Poudre River would likely contribute to or accelerate the trend of encroachment of riparian and wetland vegetation (primarily reed canarygrass and coyote willow) into the channel (Anderson 2008)."*

Comment: This is a reasonable conclusion and the magnitude and severity of this encroachment requires further examination. The Vegetation Technical Report omits this issue. It is anticipated that encroachment could have detrimental impacts to and costly management implications for City with regards to stormwater control, floodplain/FEMA compliance, mitigation of public flood hazard risks, and management of invasive species.

DEIS Section: 4.7.5 Ground Water Cache la Poudre River, page 4-40:

Statement: *"During periods of high river flow (spring runoff) for this reach of the Poudre River, the river likely recharges alluvium adjacent to the river…."*

Comment: Although the information provided here is in agreement with current scientific thought in the published literature, the Vegetation Technical Report (VTR) fails to include the role of "alluvial recharge" in supporting wetlands and riparian vegetation. *See* comments on VTR Section 6.1.2 (page 36) in Section IV.3c of these Comments.

DEIS Section: 4.10 Vegetation, page 4-44

General Comment: This section fails to address changes to, or loss of, riparian vegetation. The City has significant concerns about the future health of the riparian vegetation if the proposed action is implemented. There is a large body of scientific literature indicating reduction of spring flows result in major adverse impacts to riparian vegetation in riverine systems (Reily and Johnson, 1982, Rood and Mahoney, 1990, Tyree et al., 1995, Rood et al., 1995, Poff et al., 1997, Kranjcec et al., 1998, Lesica and Mile, 1999, Jansson et al., 2000, Nilsson and Berggren, 2000, Obedinski et al., 2001, Nilsson and Svedmark, 2002, Rood et al., 2003a, Rood et al., 2003b, Friedman et al., 2005, Stromberg et al., 2007). Failure to address riparian vegetation in this section renders the DEIS inadequate in its analysis. *See* related comments on DEIS Section 4.2.1.4, Section 4.12, and Section 4.13 in these Comments, below, and on the Vegetation Technical Report (VTR) in Section IV.3c of these Comments.

DEIS Section: 4.11 Noxious Weeds, page 4-46

General Comment: The likely increase in invasive species is a significant concern to the City. This section fails to address this issue despite a large body of scientific literature indicating how a significant reduction of spring flows would have adverse impacts to riparian vegetation and contribute or accelerate encroachment of non-native and noxious weeds into the river channel and riparian area (e.g., Lesica and Miles, 1999, Friedman et al., 2005, Stromberg et al., 2007). The City has the following specific concerns:

1. An expected reduction in native vegetation due to unprecedented drought stress and loss of opportunity for regeneration and native plant restoration. In the short term an expected loss of remnant populations of herbaceous species and of willows inhabiting higher elevations. Cottonwoods that are currently drought stressed will be affected in the near future, and healthy cottonwoods will decline in health and become increasingly disposed to disease and premature death.

2. The replacement of existing native species by non-natives with habitat needs that are distinct (different) from the native riparian species.

3. Russian olive is expected to become a significant problem under flow conditions predicted to result from NISP. This species is very difficult to eradicate once it establishes. Russian olive inhabits wetted soils but does not rely on higher spring

flow nor does it need bare areas to germinate. Russian olive has a large seed that can sprout through existing stands of grass. The City has gone to considerable expense to work to eradicate Russian olive through the Poudre River riparian corridor.

4. Tamarisk (salt cedar) invasion has been well documented in western river systems following flow modification alterations (Stromberg et al., 2007). Tamarisk seeds are available all summer long and can therefore establish as the new bare sediment becomes available anytime throughout the summer (as opposed to the short availability of cottonwoods seeds in the spring). The City has gone to considerable expense to work to eradicate Tamarisk through the Poudre River riparian corridor.

5. Reed canarygrass will continue to invade the riparian corridor because overbank events will occur much less frequently. The scouring that accompanies an overbank event tends to clear away the monoculture stands. Reed canarygrass will also be opportunistic invader of new bare sediment as the channel narrows.

6. As the soils in the current riparian forests becomes drier under project conditions, upland species would be expected to establish closer to the River, reducing the width and homogenizing the riparian habitat (terrestrialization), reducing channel capacity to convey floods.

Under the Colorado Noxious Weed Act, land owners are required to manage and eradicate noxious weeds. *See* Section 35-5-101, et seq., Colorado Revised Statutes. Therefore, if this shift towards non-native occurs as expected, the proposed action will produce injury to the integrity of City-owned properties adjacent to the Poudre River and will burden the City (and other property owners along the Poudre River) with significant additional weed control costs on these lands. The City already has made a long-term commitment to weed eradication along the Poudre River and has spent hundreds of hours per year and tens of thousands of dollars eradicating salt cedar and Russian olive. *See* related comments on DEIS Section 4.2.1.4, Section 4.12, and Section 4.13 in these Comments, below, and on the Vegetation Technical Report (VTR) in Section IV.3c of these Comments.

Finally, mitigation strategies could not be discussed in a meaningful fashion until the threat of noxious weeds along the Poudre River riparian corridor has been fully evaluated in an SDEIS and Revised Section 404(b)(1) Analysis for the proposed action, including analysis called for under Subpart H of the Section 404(b)(1) Guidelines. This further analysis is necessary to properly evaluate and address the impacts to the riparian corridor, as required under the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments.

DEIS Section: 4.12 Wetlands and Other Waters, page 4-51
Statement: *"Changes in streamflows are not anticipated to cause a loss in wetland and riparian vegetation for the following reasons."*

Comment: There are conflicting conclusions within the DEIS and supporting documents regarding impacts to riparian vegetation. These contradictions make it difficult to evaluate the consequences of the proposed action to riparian vegetation. *See also* comments on DEIS Section 4.2.1.3 and Section 4.2.1.4, in these Comments, above.

DEIS Section: 4.12, page 4-51
Statement: *"The greatest change in flow will occur on the Poudre River during high flows. These higher flows and their associated stream stages occur infrequently (a few days over the 50 year hydrologic record) and are unlikely to support wetland vegetation which typically occurs at lower elevations closer to the river."*

Comment: This statement originates from the Vegetation Technical Report. Numerous mistakes or inadequacies (such as incorrect data transfer, lack of site specific data and improper application of ecological concepts) undermine the conclusion stated above. Consequently the argument is fundamentally flawed and final conclusions are not supported or proven. *See* detailed comments on Section 6.2.6 (page 55) of the Vegetation Technical Report (VTR) in Section IV.3c of these Comments.

DEIS Section: 4.13.4 Riparian Resources Mitigation, page 4-53
Comment: Due to the conflicts within the DEIS and supporting documents, and due to lack of baseline inventory data for this resource, it is impossible to evaluate mitigation strategies. As a result, the Corps has not met its obligation to address impacts under NEPA and the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments.

DEIS Section: 5.1.6 Mitigation of Riparian Resources, page 5-7
Statement: *"Riparian resources along reaches of the Poudre River may be affected by reduced streamflows during the growing season."*

Comment: The City agrees that the proposed action may have serious consequences on riparian resources on the Poudre River through Fort Collins. These consequences have not been adequately evaluated. As a result, the Corps has not met its obligation to address impacts under NEPA and the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments.

Final comments about DEIS analysis of Vegetation within the City of Fort Collins
The City is concerned that a 25% to 71% reduction in Poudre River flows from NISP will cause unprecedented drought stress to all riparian plant species. There is a significant lack of systematic data collection and analysis, and of consistent findings within the

DEIS and between the DEIS and the supporting technical documents to evaluate these impacts. It is difficult in some areas, and impossible in others, to evaluate the environmental consequences of the proposed action on riparian resources. Again, a rigorous, objective and scientifically based assessment is necessary to properly understand the relationship between altered flow regime, changes in stream morphology, stream stage, alluvial groundwater levels and consequent changes to vegetation is necessary to evaluate these impacts and is required. The Section 404(b)(1) Guidelines call for "*appropriate factual determinations, evaluations, and tests including determination of secondary effects on the aquatic ecosystem."* Section 404(b)(1) Guidelines Section 230.10 and Section 230.11(h).

3c. Comments on the Vegetation Technical Report (VTR)

VTR Section: 5.6 Cache la Poudre River and South Platte River Study Areas, page 31
Statement: *"Palustrine Persistent Emergent and Palustrine Scrub-Shrub Wetlands have established adjacent to the active channel and in depressions in the floodplain."*

Comment: The VTR acknowledges the existence of the specified wetlands along the impacted segments of the Cache la Poudre River. Wetlands in this study area were identified using the Colorado Division of Wildlife (CDOW) riparian mapping project which is based on satellite imagery. This is not sufficient for a DEIS-level analysis. Many small wetlands may be overlooked or wrongly characterized. *See* comments on DEIS Section 4.2.1.3 in Section IV.3b of these Comments.

It is important to note that similar types of wetlands identified in the proposed Glade Reservoir site and in the U.S. Highway 287 realignment study area were rated high or moderate for the following values:.

- general wildlife habitat
- sediment/shoreline stabilization
- production export/food chain support
- ground water discharge/recharge
- sediment/nutrient/toxicant removal
- dynamic surface water storage.

Wetlands along the Poudre River would probably rate moderate to high for most of these categories. In addition, Poudre wetlands might rate high for recreation and educational potential as well. *See* generally Part V of these Comments.

VTR Section: 6.1.2 Effects to Riparian Vegetation, page 35
Statement: *"The assessment of potential effects to riparian and wetland vegetation in the Cache la Poudre River and South Platte River study areas was based primarily on*

estimated changes in average monthly flows and stream stage associated with each alternative."

Comment: Riparian vegetation responds to extreme river flows (highs and lows) that are not best represented by monthly averages. For example, an average reduction of flows for the month of June of 1.77 feet may mean a range of daily reductions from 1 foot to 6 feet. If during a period of seven days the water table is 6 feet lower than current conditions, the riparian vegetation will be significantly impacted. Even though the average reduction seems modest, the consequences of the extremes are what truly matters to the vegetation. Daily flows were modeled for the Spells analysis, and this daily flow data should have been, but was not, used throughout the VTR.

Furthermore, in its scoping letter, EPA (EPA Scoping Comments Letter, page 2) recommended the following: "*The hydrologic analysis should be sufficiently detailed to provide the necessary information for the assessment of biological impacts. Monthly average discharge is usually insufficient for such analysis. At a minimum, wet, average, and dry year analysis should also be included*." The City concurs with this assessment. Analysis consistent with EPA's recommendation should be included as part of an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.1.2 Effects to Riparian Vegetation, page 35
Statement: *"Key considerations were potential changes in stream morphology, changes in stream stage or reservoir elevation, and changes in alluvial ground water elevation associated with changes in stream stage…."*

Comment: It is unclear how the analysis considers future changes to stream morphology. The issue of fine sediment deposition is omitted from this discussion despite its having been identified as an issue in the scoping process for the DEIS, and regardless of any other potential short or long term changes in stream morphology. The issue of encroachment, mentioned elsewhere in the DEIS, is not included in the VTR. "*Changes in reservoir elevation…"* is not mentioned anywhere in the analysis, nor is the specific reservoir identified. Measurements of alluvial groundwater elevations were not made. Thus, the City finds the analysis inadequate to support the findings of the VTR or DEIS and inconsistent with the Section 404(b)(1) Guidelines.

VTR Section: 6.1.2 Effects to Riparian Vegetation, page 37
Statement: *"Field visits along the Cache la Poudre River and South Platte River study areas from the Munroe diversion to the Kersey gage were used to verify aerial photos and field check: the location of riparian and wetland vegetation, the influence of flood irrigation, other land use practices, and tributary streams or ditches on riparian and wetland vegetation…."*

And;

VTR Section: 6.1.2 Effects to Riparian Vegetation, page 43
Statement: *"On August 23, September 8, and October 31, 2006 and November 5 and 6, 2007, ERO conducted field reviews along the Cache la Poudre and South Platte rivers."*

Comment: Only 5 field days over a period of 2 years were allocated to visit 12 sites that spanned a distance along the River of approximately 50 miles. It is unclear how these scattered snapshot site visits and qualitative observations provided sufficient data to assess "*the influence of flood irrigation, other land use practices, and tributary streams or ditches on riparian and wetland vegetation*."

Observation of wet soils and of "*water moving towards the river"* (page 54) is cited as key evidence for the major conclusion of this VTR section that "*the riparian vegetation appears to be supported by lower more frequently occurring flows and supplemental sources of hydrology*."

The Section 404(b)(1) Guidelines clearly indicate "*appropriate factual determinations, evaluations, and tests are necessary to assess impacts to the aquatic resources" See* Section 230.10. Five site visits to various river reaches is wholly inadequate to make a quantitative scientific assessment of these factors.

VTR Section: 6.1.2 page 36
Statement: *"Much of the Cache la Poudre River has been physically altered… These activities have limited the development of riparian vegetation by decoupling the historical floodplain from the dynamics of the river and alluvial ground water… Therefore, the evaluation of riparian resources and the potential effects of changes in streamflow focused on river reaches with riparian resources that appear to still be linked to some degree to the dynamics of river flows and shallow alluvial ground water levels that provide a supportive hydrology for riparian and wetland vegetation…. These reaches for the riparian resources appear to be linked to the river to some degree are referred to as sensitive reaches, because of their potential to be sensitive to changes in streamflows."*

Comment: While it is true that anthropogenic practices have altered the River and floodplain and that specific areas are more linked physically to River flows, there is no evidence to back the assertion that other reaches (those not identified as sensitive) have no relationship to the flows in the River due to *decoupling* of the floodplain from the River and alluvial groundwater. This "decoupling" is purely speculative and there is no scientific basis for asserting that less sensitive reaches are not influenced by the flows in the River in a significant way.

It is more likely that there is a complex groundwater flow pattern in this area where the entire Reach receives significant fluvial "recharge" in the spring via the rising stream stage and the probable corresponding rise in the alluvium. Therefore, the majority of the river segments are probably "losing reaches" during spring flows. Return flows from agriculture and other human activities make these gaining reaches in the autumn. The

many gravel pit ponds (lined and unlined), further complicate groundwater movement patterns. The connectivity of the River to adjacent groundwater tables is undoubtedly complex and deserves a quantitative evaluation.

In another example of internal contradictions within the DEIS, the following statement from DEIS Section 4.7.5 appears to contradict the findings made in VTR Section 6.1.2 (page 36) and to more closely align with the City's perspective on this issue:

> **DEIS Section: 4.7.5 Ground Water Cache la Poudre River, page 4-40**
> *"During periods of high river flow (spring runoff) for this reach of the Poudre River, the river likely recharges alluvium adjacent to the river. As high flows decrease and irrigation of adjacent fields increases during the summer months, ground water probably flows toward the river. There is insufficient information to determine whether the river is gaining or losing during the winter months. It is probable that certain portions of the river receive ground water due to the delay in ground water flow from irrigated fields some distance from the river, and there may be neither recharge nor discharge to the alluvium in other portions of the river."*

As discussed throughout these Comments, there are potential negative effects from the altered flow regime predicted to result from NISP along the entire course of the River. Although the channel through the City is heavily affected, and the connection with high flows may not be *obvious*, the varying magnitudes of streamflow under current conditions still perform important ecological functions through the entire Reach and, in particular, exercise substantial influence over riparian and riverine vegetation.

VTR Section: 6.1.2 page 37
Statement: *"The assessment of potential effects to riparian resources focused on the potential for changes in channel maintenance flow to affect the channel and in turn the conditions necessary to support riparian vegetation. The magnitude, duration, timing, and frequency of channel maintenance flows can affect riparian vegetation, which in turn affects channel dynamics (Schmidt and Potyondy 2004)… These relationships may vary substantially in highly altered channels. Schmidt and Potyondy (2004); however, noted that although bankfull elevation is related to vegetation along the channel, a range of channel maintenance flows is necessary to keep vegetation from encroaching on the channel."*

Comment: Although the ecological background provided in the cited paragraph is consistent with ecological theory, this statement indicates that the VTR applies these concepts, but it does not. The VTR does not adequately address the "*range of maintenance flows*." The analysis of magnitude, duration, timing and frequency was incomplete and inadequate. Final conclusions ignored the moderately high flow. The role of scouring is not discussed and vegetation encroachment is omitted in the VTR. The analysis in the VTR considered only impacts to overbank flows and omitted any discussion on the important role of the range of flows.

VTR Section: 6.1.2 page 38
Statement: *"Stream stage (the elevation of water in the channel) can affect the elevation of the alluvial ground water, and may in turn affect riparian vegetation."*

Comment: The VTR repeatedly refers to the relationship between stream stage and alluvial groundwater. However, alluvial groundwater levels were not measured. The influence of moderately high flows (and the reduction thereof under project conditions) on recharging the groundwater was omitted from the actual analysis. The recharge to the alluvial groundwater under the current flow regime by moderate flows cannot be ignored in this assessment when the changes anticipated for the proposed action will greatly reduce the frequency of the moderate flows. This issue is another that must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.5 Riparian Vegetation along the Cache la Poudre and south Platte Rivers, page 40
Statement: *"Although supportive hydrologic conditions are essential for the maintenance of wetlands, simple cause-and-effect relationships are difficult to establish (Mitsch and Gosselink 1993)….. The ground water table adjacent to a stream may be higher or lower than the stream, depending on the discharge/recharge relationship between the stream and adjacent ground water."*

Comment: Difficulty establishing such linkages does not justify ignoring them, especially where assessment of this issue is essential under the Section 404(b)(1) Guidelines. *See* comments on VTR Section 6.1.2 (page 36), above. This statement is fundamentally deficient and should be reanalyzed in a Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.5 page 45
Statement: *"Table 2. High and moderate flows associated with cross sections used for spell analysis and changes with action alternatives..."*

The title for this table refers to "high and moderate flows". This is the first time these terms are used in the VTR. Also, in the body of the table there are references to "high and low" flows. No information is provided to quantitatively or qualitatively describe what is meant by "high," "moderate," and "low" flow.

VTR Section: 6.2.5 page 45
Comment on the data in the body of Table 2

Comment: The final conclusions in the VTR refer to data from this Table 2 as a key piece of evidence. The table was created by transferring data from Table 3.11 in the

River Morphology and Sediment Transfer Technical Report (RMSTTR). Significant mistakes were made during the transfer of the data.

Specifically, there is a column in Table 2 titled "*Number of Spells (days)"*. The corresponding column in Table 3.11 in the River Morphology Technical Report uses the title "*Number of high spells*" which is explained in the body of the text as "*…the number of times in the period for record that the flow threshold is exceeded. A spell must be at least 1 day long and spells must be separated by 3 days*." Table 3.11 also has a column titled "*Total duration of all High Spells (days)"* and this would have been the appropriate data to transfer to Table 2 in the VTR. To clarify, Table 2 is presented below. The correct values (the values presented in the RMSTTR in Table 3.11) have been provided in parenthesis and italicized in the 3rd and 4th columns.

Table 2. High and moderate flows associated with cross sections used for spell analysis and changes with action alternatives.

Cross Section Spell Threshold (cfs)	Number of Spells (days)1	Baseline	Project
234557	2,000 (low)	17 *(93)*	5 *(28)*
	3,600 (high)	4 *(13)*	0 (n/a)
233367	1,600 (low)	19 *(136)*	9 *(53)*
	3,400 (high)	5 *(19)*	0 *(n/a)*
187158	1,400 (low)	20 *(178)*	12 *(76)*
	2,400 (high)	10 *(51)*	5 *(16)*
152250	200 (low)	167 *(1235)*	136 *(921)*
	400 (low)	93 *(697)*	73 *(481)*
	2,300 (high)	9 *(56)*	4 *(19)*
	3,800 (high)	3 *(8)*	0 *(n/a)*
133345	1,900 (low)	28 *(120)*	7 *(30)*
	3,600 (high)	5 *(14)*	1 *(1)*

This error undermines subsequent conclusions in this section. The discussion on pages 55-58 of the VTR uses these incorrect values to draw final and significant conclusions about the influence of overbank flows on riparian vegetation. For each cross section the report refers to the frequency of overbank flows and concludes that *"neither of these flows currently occur at a frequency sufficient to provide hydrologic support for riparian vegetation."* With the correct data set this conclusion would be different. The issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.5 page 46
Statement: *"Reductions in streamflow will result in reductions in stream stage... In areas where the water table decline was less than 3.1 feet, cottonwood mortality was between 7 percent and 13 percent. In another study, Scott et al. (1999) noted that over a 3-year period in medium grained alluvial sands, sustained declines in the water table of greater than 3.1 feet resulted in 88 percent mortality of plains cottonwood. The study further noted that gradual water declines of about 1.5 feet had no measurable effect on mortality, stem growth, or live crown volume (Scott 1999).*
Corresponding statement page 51: *"Lincoln Gage. During the growing season the largest changes in mean monthly stream stage (up to -1.77 ft) would occur during wet years,…In addition, in May, stream stage would be about 0.71 ft below baseline conditions …in average years up to 0.96 feet in June…These changes in vegetation are unlikely to cause a loss of wetland or riparian vegetation…"*

Comment: The Scott et al. (1999) study was improperly applied to the Poudre River study area. Scott et al. (1999) reported cottonwood response to changes in the alluvial ground water table. The conclusion from page 51 of Scott et al. (1999) quoted above refers to "*changes in mean monthly stream stage."* The VTR provides no data on the relationship between stream stage and ground water levels or the distinctions that may apply in this highly modified urban environment, and these relationships cannot be assumed.

Despite this flaw, the VTR uses the value of 3.1 feet as the factor that would cause *88% mortality* and a 1.5 foot decline as a change that would cause "*no measurable effect on mortality, stem growth, or live crown volume…"*and then proceeds to omit additional relevant results from this study. Scott et al. observed a 1.5 foot decline to cause "significant declines in annual branch growth increments." Given the relatively short duration of the observation period (3 years) relative to the life of a cottonwood, Scott et al. distinguish between severe water stress (rapid mortality) and sub-lethal water stress (reduced growth). The authors note that the trees experiencing sub-lethal water stress "may be more vulnerable to subsequent periods of low precipitation and high temperatures". Given the numerous studies documenting physiological and morphological stresses on cottonwoods resulting from dewatering (Reily and Johnson, 1982, Tyree et al., 1994, Obedinski et al., 2001, Rood et al., 2003), and the incorrect application of stream stage instead of ground water, the analysis in the VTR is inadequate and flawed. The issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

Scott et al. also discuss many site specific ecological and physiological factors which influence the responses of cottonwoods in their study. The article concludes by asserting results are valid within the specific parameters of the study site. As well, the authors acknowledge that "clearly, other combinations of antecedent water table environments, meteorological conditions, drawdown patterns and soil characteristics are possible and beyond the scope of this study…" (Scott et al., 1999). The VTR fails to discuss the characteristics that distinguish the Poudre River environment from the site of the referenced study, or to analyze the significant of those distinguishing characteristics.

Another significant problem with the analysis is the use of the monthly changes in stream stage. Given that daily flows were modeled for the Spells analysis, it is unclear why monthly values were used here. Along with many other river ecologists, the same researchers (Scott et al.) have observed that riparian vegetation is extremely sensitive to changes in minimum and maximum flows (Auble et al., 1994). Without daily flow data, the changes to flow boundaries are unknown, and the analysis is incomplete.

The potential impact of NISP on cottonwoods is extremely important to the City. As stated by Rood et al. (2003a) "Cottonwoods not only have intrinsic environmental and aesthetic value, they also provide the foundation for the riparian forest ecosystem."

Cottonwoods are a keystone species. A keystone species is a species that has a disproportionate effect on its environment relative to its abundance (Power et al. 1996). Such species affect many other organisms in an ecosystem and help to determine the types and numbers of various others species in a community

Such an organism plays a role in its ecosystem that is analogous to the role of a keystone in an arch. While the keystone feels the least pressure of any of the stones in an arch, the arch still collapses without it. Similarly, an ecosystem may experience a dramatic shift if a keystone species is removed, even though that species was a small part of the ecosystem by measures of biomass or productivity.

The City has spent decades and made significant financial investment in protecting the Poudre River floodplain, its habitat, and its aesthetic and recreation resources for the people of Fort Collins and Larimer County. A more detailed, science-driven data analysis is necessary to evaluate the fate of cottonwood forests under the proposed action. The issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.5 pages 47-48
Statement: *"Wetland vegetation, especially herbaceous wetland vegetation, may be more sensitive to changes in ground water levels… Six inches (0.5 feet) is a conservative estimate of the change in stream stage that could affect wetland vegetation…in other reaches where wetland vegetation …it is likely that this (wetland) vegetation is supported by commonly occurring lower flows and may adjust over time to any changes in elevation."*

Comment: This section of the VTR is difficult to understand and evaluate. There seems to be confusion about the fact that areas may contain jurisdictional wetlands, but riparian areas may also include a mosaic of other fluvial influenced areas that may not be "wetlands" in the strict legal sense but are uniquely riparian (i.e. they exist specifically because of the dynamic river flows). In the absence of an inventory of jurisdictional wetlands, modeling of groundwater levels, and alluvial recharge, these conclusions are not supported on a scientific basis.

Furthermore, the claim that the herbaceous vegetation "*may adjust over time to any changes in elevation*" (we assume water table elevation) is not supported by data collection, vegetative modeling, or other research. Rather than existing plant communities adjusting over time, it is more likely that the process of non-native vegetation out-competing native species will be further accelerated, or that vegetation characteristic of wetlands will simply disappear.

VTR Section: 6.2.5 pages 51
Statement: *"In April and September, under Alternatives 2, 3, and 4, mean monthly stream stage during the growing season would change very little (ranging up to -0.01 feet), compared to baseline conditions."*

Comment: This is the first mention of "baseline conditions" in the VTR. Baseline conditions are not defined. It might be that this is a reference to the Baseline conditions modeled in the River Morphology and Sediment Transfer Technical Report (RMSTTR), but this unclear. This is relevant because if baseline conditions are developed from a dry year or based upon average low river flow, plants are more likely to be sensitive to smaller changes in river flow than if the baseline conditions are developed from a higher baseline. In other words, a reduction in stage by 0.5 foot at low flow (low baseline) would have a greater effect than the same reduction in flow at a higher baseline flow. The baseline issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.6 Riparian Vegetation Impacts Summary, page 53
Statement: *"Based on the preliminary analysis using mean monthly flows and stage, it was determined that additional studies were needed …these studies included representative cross sections, generated daily flow data for key locations…"*

Comment: If daily flow data was generated in the additional studies suggested in this VTR section, that data should have been used throughout this analysis and disclosed. Instead, a monthly timestep was used, which is essentially meaningless for assessing impacts to vegetation and ignores the physiological stress experienced by plants under short term drought stress. A discussion based on daily reductions during the peak runoff would have created a useful comparison under which to evaluate the alternatives. This should be done in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.6 page 53
Statement: *"Generally, NISP would have less effect on the more frequently occurring moderately high flows, a greater effect on high-flow events, and little effect on the rare large flood events."*

Comment: This statement is unclear and is in direct conflict with other supporting documents. For example, Section 4.1.4 of the River Morphology and Sediment Transfer Technical Report (RMSTTR) (page 4.5) states "*…In summary, the frequency of flooding would be less throughout the study area after the Project. The most consistent effect is on moderate floods where a 4-6 year average recurrence interval would occur on average once in 20 years after the Project."* Because there is no definition of "more frequently occurring moderately high flows" and "high-flows" provided, it is not possible to analyze this statement, particularly given the significant lack of consistency with conclusions in other DEIS documents. These issues must be reconciled in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.6 page 53
Statement: *NISP's effects on flow duration for the Poudre River would be the greatest for the upper reaches through Fort Collins. The average annual range in the duration of flows of 800 cfs to 3,000 cfs would be reduced from 45 days per year to 28 days per year, and the mean daily flow would be reduced from 219 cfs to 158 cfs. ….. The average recurrence interval for flows of 2,000 cfs, a relatively high flow, in the Laporte through Timnath reaches would double from about 1 to 2 years; the average recurrence interval for a flow of 3,000 cfs would increase from about 1 in 4 years to 1 in 20 years.*

Comment: The role of peak flows in maintaining recruitment patterns, age-class structure, and sustaining riparian communities through rising alluvial groundwater or overbank inundation is discussed earlier in the VTR but is not considered in the statement quoted here. A 50% decrease in number of days these high flows will occur and the doubling or quadrupling of recurrence intervals for high flow events is very likely to have a major adverse impact on the riparian vegetation because of the critical functions served by these types of flows.

VTR Section: 6.2.6 page 53-54
Statement: *"Based on these projected changes in flows and assessment of representative cross sections, the following conclusions were reached regarding trends and effects to riparian vegetation….."*

The sites typically have sources of supportive hydrology in addition to the river (e.g., gravel pit ponds elevated above the river, tributary drainages, seeps, or irrigation ditches, or these in combination). These supplemental sources of water were evident even in early November during low flows as many of the sites reviewed had areas

that were saturated and water was observed moving toward the river from nearby sources at elevations higher than the river. Wetlands within these sites were saturated in the fall when streamflows were low."

Comment: As stated in comments on VTR Section 6.1.2 (page 37), above, snapshot observations, and zero groundwater data is not sufficient evidence upon which to derive this conclusion. According to Section 404(b)(1) Guidelines Section 230.5 (e), the DEIS must… "*evaluate the various physical and chemical components which characterize the non-living environment of the waters…including its dynamic characteristics*." The Section 404(b)(1) requirements are not satisfied by "*observations of wet ground in November.*" This issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

VTR Section: 6.2.6 page 54

"Typically, the oldest trees occur along the margins and higher elevations of the floodplain (i.e., farthest from the river), and many of these older trees are decadent."

Comment: It is unclear how the authors identified the age of the cottonwood trees. The forestry literature is replete with data demonstrating that stem diameter is often a poor indicator of tree age. Tree coring (which is reliable) was not mentioned. Given the human history of the area (including plantings, ditches) there is probably a complex mosaic of different age cottonwoods throughout the study area.

VTR Section: 6.2.6 page 55-58

Statement: *"…..The NISP action alternatives would reduce the frequency of flows of 3,400 cfs from 17 to 5 days and flows of 1,600 cfs from 19 to 9 days for the 50 years of hydrologic record (Anderson 2008). Neither of these flows currently occur at a frequency sufficient to provide hydrologic support for riparian vegetation. It is likely that most of the supportive hydrology comes from the lower more frequently occurring streamflows and supplemental sources such as the ditch and nearby ponds."*

Comments: Due to incorrect transfer of data from the River Morphology and Sediment Transfer Technical Report (RMSTTR), the results of this analysis are grossly misrepresented. For example, it should state that flows of 1,600 cfs would be reduced from 136 days to 53 days. These mistakes are fundamental and would fundamentally modify the author's conclusions. The baseline issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

Furthermore, the argument ignores the important increase in water available to riparian vegetation during moderately high flows (not overbank flows of 1,600 or 3,400 cfs). It is well documented that these moderately high flows cause a corresponding rise in groundwater levels in riparian soils, which the DEIS recognizes elsewhere. *See, for example,* DEIS Section 4.7.5 (page 4-40): … "*During periods of high river flow (spring runoff)… the river likely recharges alluvium adjacent to the river."*

VTR Section: 6.2.6 page 55-58
General comment about interpretation of Spells analysis: It is important to note that the River Morphology and Sediment Transfer Technical Report (RMSTTR) provides a brief "Interpretation of the Results of the Spells Analysis". Its conclusions are inconsistent with those drawn in the VTR in this Section. While the VTR essentially concludes that there will be no impact to the riparian areas along the Poudre River due to hydrologic changes, the RMSTTR excerpt below indicates recognizable, foreseeable changes to flow magnitude and duration and consequential negative impacts to vegetation:

> **RMSTTR Section 4.1.5, page 4.5**
> *"The spells analysis reported in Chapter 3 further elaborates the likely impact of the project by reporting on both occurrence and duration of flow events that correspond to flow thresholds with a particular significance to geomorphology or colonization and survival of riparian vegetation. In general, the analysis reveals a substantial reduction in the occurrence and duration of high flow events throughout the study area under Project conditions. At all of the stations that were analyzed, the number of overbank flows would be reduced by as much as 50% and the average duration of the remaining events would also be decreased.*
>
> *At all the stations that were examined, the number of occurrences of significant overbank flows has decreased markedly. For two stations in the Fort Collins Reach, the number of occurrences of significant overbank flows in the modeled period (1975 to 1999) decreases from 4 or 5 under Baseline conditions to zero with the Project. At another station in the Fort Collins Reach, and also a station downstream in the Timnath Reach, the occurrence of significant overbank flows is now halved (from 19 to 10 occurrences at one station and from 10 to 5 occurrences at the other). The reduction in occurrence is accompanied by a 50 to 70% reduction in the total duration of the overbank flows. There is a similar impact on the lower flow thresholds although the effect is generally less dramatic at the smaller flows.*
>
> *As well as having an important influence on colonization and maintenance of vegetation, the occurrence and duration of flows that inundate channel benches and the floodplain is also important to sediment movement and the morphology of the channel. An elongation of the average time between flow events that are large enough to be capable of scouring the channel gives a longer period for vegetation to establish. A shorter duration of scouring flows means that less net channel change will occur. A trend toward fewer and shorter high flow spells is apparent throughout the study area."*

4. Aquatic Habitat Quality and Aquatic Life

4a. General comments

The City and authors of the DEIS recognize the significance of the Poudre River through Fort Collins as a transition area from a cold water to warm water river. Areas of physical transition from one habitat to another are typically rich in species diversity and sensitive to external environmental perturbations. The City is particularly concerned that lack of field data and limited modeling efforts of the DEIS are not likely to lead to an accurate portrayal of the possible environmental consequences to the aquatic biological resources from the proposed action. Thus, contrary to the conclusions of the DEIS, the City believes that there may be major adverse impacts that could reduce or eliminate certain aquatic life in the Poudre River as a result of the proposed action. Further, the City believes that degraded water quality, large reduction in peak flow, channel narrowing and increased sedimentation will result in reduced ecological function that likely cannot be mitigated. Because the DEIS does a poor job of describing the direct and indirect impacts to aquatic resources resulting from the proposed action, its discussion of mitigation measures is premature at best, and does not suffice to meet the requirements of NEPA and the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for more discussion of this issue generally.

4b. Specific Comments on DEIS

DEIS Section: 3.15.5.1 Macroinvertebrate Populations, Cache la Poudre River, pages 3-74 - 3-76
Statement: *"Shieh et al. (1999) collected macroinvertebrate samples from the Cache la Poudre River…"*

Comment: In addition to Shieh, *et al*. (1999) the following relevant literature should have been reviewed to provide a more comprehensive analysis of the macroinvertebrate communities of the Poudre River, Fort Collins, and to support conclusions throughout this section:

- Grotheer et al., 1994.
- Shieh et al., 2002.
- Shieh et al., 2003.

Additionally, Dr. Douglas A. Rice, Laboratory Director, Environmental Health Services, Colorado State University, has thirty years of macroinvertebrate data available for the Poudre River through the study stretch and would be an essential resource for further evaluation.

This entire section of the DEIS is uninformative and the conclusions are not completely accurate based on the available data. The section basically concludes that "based on 2005 data, as well as earlier data, abundant and diverse macroinvertebrate populations inhabit

the Poudre River within the study area." This statement is not accurate upon examination of other published and unpublished data (Grotheer et al., 1994, Rice unpublished data, Shieh et al., 1999, Shieh et al., 2002, Shieh et al., 2003). In fact, macroinvertebrate diversity is significantly reduced and community structure and function significantly altered in the Poudre River through Fort Collins. For example, when using the NAWOA data set (based on USGS 2003, as cited on page 3-76 of the DEIS), in all reaches combined at the mouth of the Canyon at least 122 macroinvertebrate taxa were identified, 87 taxa at a Fort Collins site, and East of Interstate 25 only 45 taxa were found (Kondrateiff 2008).

Furthermore, the statement that *"at all sites, indicating that healthy invertebrate communities inhabit the Cache la Poudre River within the study area [interpreted from Shieh et al.. 1999]"* is misleading because

1. pollution sensitive and strongly rheophilic taxa such as Plecoptera (stoneflies) occurred only upstream of Fort Collins;
2. diversity clearly decreased downstream [Site 1 upstream of Fort Collins, about 30 taxa; Site 2 below Fort Collins, 21 taxa];
3. Smaller and faster growing taxa with multiple generations (e.g. chironomid midges) that are pollution tolerant and are slow water forms dominate sites below Fort Collins. (Interestingly, this is actually indicated in Section 3.15.5.1: "The number of EPT taxa [pollution sensitive and rheophilic aquatic insect orders: Ephemeroptera (mayflies)/Plecoptera (stoneflies)/Trichoptera (caddisflies)] at each site ranged from **five** taxa at I-25 to **15** taxa upstream").

Other than the Physical Habitat Simulation (PHABSIM) modeling (which does not consider water temperature), no other analysis is presented in the evaluation of the proposed action (reduced peak flows and seasonal snowmelt floods) of the structure and function of the macroinvertebrate community and benthic habitat quality of the Poudre River through Fort Collins.

Similarly, PHABSIM results are not useful for judging future impacts. Therefore, more weight should be given in a DEIS to the results of the stream morphology, water quality and hydrology reports. The detrimental effects of degraded water quality, large reduction in peak flow, channel narrowing and increased sedimentation predicted to result from NISP would result in less ecological function than currently exists in this river segment, and the DEIS fails to adequately assess those impacts.

DEIS Section: Section 4.15.1.1 Hydrology, page 4-59-60
Comment: As stated earlier, the use of mean monthly data is not sufficient for a meaningful biological analysis. Mean monthly flow masks the range of values that occur within a month. In months when flows are increasing (ascending hydrograph limb) or decreasing (descending hydrograph limb) during the month, the mean monthly value does not represent the conditions experienced by the aquatic fauna. A daily flow regime should be used to determine impacts to aquatic fauna and habitat. Daily flows for typical

wet, average, and dry years should be simulated and analyzed. The hydrologic regime issue is fundamental to evaluating water project impacts and must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

DEIS Section: Section 4.15.2.1.1 Upstream of Fort Collins, page 4-61
Statement: "*Water quality and riparian vegetation are not expected to change from existing conditions for any of the action alternatives in this segment of the river (ERO and HDR 2008; ERO 2008a) and would have no effect on aquatic biological resources.*"

Comment: This blanket statement disagrees with the conclusions presented in the Water Quality Technical Report (WQTR) (page 36): "*Temperatures greater than 20 C have occasionally occurred between mid-July and mid-September; the predicted flow decreases could result in river temperatures that exceed 20 C more frequently and for longer periods. A dissolved oxygen concentration less than the spawning standard of 7 mg/l has occurred in the past; with reduced flows and warmer stream temperatures, the dissolved oxygen standards could be more frequently exceeded.*" This statement from the WQTR indicates a minor to moderate impact to biological resources and not this "no effect" conclusion stated on DEIS page 4-61. *See also* the comments on Vegetation, above in Section IV.3 of these Comments.

DEIS Section: Section 4.15.2.1.1 Upstream of Fort Collins, page 4-61
Statement: "*The reductions in peak flows also would tend to reduce movement and scouring of the substrate, which would tend to benefit benthic invertebrates that live in the substrate and also tend to benefit longnose dace, a common minnow species in the substrate in this segment.*"

Comment: Research has shown that substrate movement is necessary in healthy river ecosystems (Bunn and Arthington, 2002). Annual runoff of snow melt to dependent streams is the process responsible for habitat creation and maintenance. Reductions in peak flows of the magnitude predicted to result from NISP and their scouring effect can result in embedding the channel substrate and subsequent loss of interstitial (soil pore) space utilized by benthic invertebrates.

The City does not agree that longnose dace live in the substrate. This species is generally found close to the bottom substrates but live on the surface of the cobbles and gravels. The only life stage of this species that is small enough to utilize the interstitial spaces would be larval forms. Spawning occurs for an extended period during the summer. This reproductive strategy is geared toward a higher probability of timing the spawn period with snow melt peak flows.

Similarly, benthic invertebrates are adapted to snow melt runoff, and the movement of the stream substrate is beneficial to the habitat. The City does not agree that a non-mobile substrate during peak flows is beneficial. In fact, the reduction in scouring flows to remove fine substrate that NISP is predicted to cause would be detrimental by allowing

fine sediments to either remain in place (go un-scoured) or settle in the water column which in turn continues to embed the channel substrate. Continued channel embedding is likely to result in a loss of aquatic diversity, including invertebrates and fish.

DEIS Section: Section 4.15.2.1.1 Upstream of Fort Collins, page 4-61
Statement: "*Therefore, the information on hydrology and habitat availability for fish and invertebrates indicates that the action alternatives would result in a minor beneficial effect to fish and invertebrate communities in this segment of the Poudre River (Table 4-11). There would be increases in abundance of fish and invertebrates and possibly increased number of species of invertebrates.*"

Comment: In contradiction to the above-quoted statement, the changes that would result from the action alternatives would not be beneficial to fish and invertebrates. Page 4-63 of the DEIS states that "…*the adverse effects of slightly degraded water quality, channel narrowing, and sedimentation*" is likely to cause significant impacts to fish and invertebrate populations, confirming that impacts would not be beneficial. Further, the DEIS incorrectly assumes that the water quality, channel narrowing and sedimentation impacts from NISP would be slight. As discussed at length above, all of these impacts would be much more significant than acknowledged in the DEIS. In addition, the lack of sediment flushing and embedding of the channel substrate with increased water temperatures as a result of the proposed action will also contribute to environmental conditions unsuited to healthy fish and invertebrate life. The cumulative effect of these negative impacts from NISP will be detrimental and will reduce or eliminate important native species and/or eliminate the opportunity for their conservation/reintroduction. The DEIS has not collectively considered these factors as a cumulative impact. The overall result for this section of the River from the action alternatives would be a major adverse impact that must be, but has not been, identified or evaluated in the DEIS. *See* Section 404(b)(1) Guidelines Sections 230.31, 230.51. *See also* Section II.1a of these Comments.

DEIS Section: Section 4.15.2.1.2 Near Fort Collins, page 4-61
Statement: "*Changes to channel morphology, increased sedimentation, degraded water quality, and the greater occurrence of low flows would be detrimental to both fish and invertebrates. The adverse effects would result in lower abundance and fewer species of fish and invertebrates. These minor adverse effects would occur gradually over time, and fish and invertebrate communities would adapt to the new flow regime and channel morphology.*"

Comment: The changes to the River from NISP would be detrimental to both fish and invertebrates, and would constitute more than a "minor adverse effect". According to the methods used for impact analysis, loss of species diversity and abundance would be a "moderate or major adverse effect". The stated conclusion that NISP would result in lower abundance and the loss of species meets the criteria to be a major adverse effect. Fish and invertebrates would not "adapt" but would be forced to conform to the new flow regime, degraded water quality, and channel conditions. The result could be a major

adverse negative effect to existing biological resources up to and including localized extirpations of existing fish and invertebrate assemblages.

Furthermore, it should be noted that the DEIS Statement quoted above concludes that there will be contrasting impacts to these two referenced river reaches. It is very unlikely that the impacts will differ from a minor beneficial effect to a minor adverse effect in adjacent river reaches.

DEIS Section: Section 4.15.2.1.3 Fort Collins to I-25, page 4-63
Statement: *"The action alternatives would have a minor to moderate beneficial effect to fish and invertebrate communities in this segment of the river (Table 4-11). This would result in increased abundance and number of species of fish and invertebrates."*

Comment: This conclusion is based mainly on the result of the PHABSIM analysis. As noted for other sections of the River where channel changes are predicted, PHABSIM results are not useful for judging future impacts. Therefore, more weight should be given to the results of the stream morphology, water quality and hydrology reports. The detrimental effects of degraded water quality, large reduction in peak flow, channel narrowing and increased sedimentation would result in less ecological function than currently exists in this segment of the River. As with the next upstream reach, this is likely to result in the loss of species and abundance and not an increase in species and abundance. There will be major adverse effects to this river segment from NISP. This issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

DEIS Section 5.8.3 Temperature and Dissolved Oxygen, page 5-16
Statement: *"To control adverse impacts to the temperature of the Poudre River, the District will implement, to the Corps' satisfaction, the means to mitigate any significant adverse effects of Glade Reservoir releases on the temperatures of the Poudre River. Discharge to the Glade forebay and the Poudre River will be fully aerated by the energy dissipation structures."*

Comment: The District's commitment to mitigate for the impacts of temperature variation and dissolved oxygen levels on the cold water fishery requires more detail to meet the requirements of the Section 404(b)(1)Guidelines. More information is required concerning the target minimum stream flows in the reach and the District's operational response when temperatures exceed those identified by cold water fishery experts. Without additional detail or commitments, these vague assertions and assurances do not suffice to address the serious harms to the aquatic ecosystem in the City. *See* Section II.4b of these Comments.

4c. Comments on the Aquatic Biological Resources Technical Report (ABRTR)

ABRTR Section: 2.2, page 31
Statement: *"All three of these other resource areas are conducting additional studies and when these studies are done, the resulting effects on aquatic organism may have to be revised."*

Comment: This statement is in reference to the Water Quality Technical Report (WQTR), Vegetation Technical Report (VTR), and River Morphology and Sediment Transfer Technical Report (RMSTTR). It is not clear when this additional analysis will be completed and whether the comment period would be extended for public review of the revised ABRTR. The ongoing need for this work further confirms the inadequacy of the DEIS and the need for an SDEIS to allow meaningful public review and comment on this issue.

ABRTR Section: 2.2.1. Approach to Analysis, page 32
Statement: *"From approximately the western edge of Fort Collins downstream to approximately Interstate 25, the Cache La Poudre River is a transitional stream from coldwater to warm water habitat."*

Comment: The City agrees with this statement and notes that the River in this transitional reach supports both coldwater and warmwater species. However, the Water Quality Technical Report (WQTR), upon which the ABRTR depends for information regarding changes to water quality to result from NISP, considers the River from approximately Shields Street downstream as warm-water. Therefore, the conclusions in the ABRTR regarding the environmental consequences from NISP do not address impacts to the coldwater species. The data and analysis of environmental consequences must address the impacts to the existing coldwater biological resources downstream to approximately Interstate 25. This would require additional analysis of water quality; in particular, water temperature changes as a result of the proposed action. Effects of the proposed action on water temperature and the potential impact to the aquatic resources were an important factor noted during project scoping. This issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

ABRTR Section: 2.2.2. Hydrology, page 33
Statement: "*The comparison of hydrologic parameters between alternatives was the primary tool in this report for evaluating the potential effects on aquatic resources in the streams in the study area. In this report, we used summaries of mean monthly flow at nine locations on the Cache La Poudre River and one location on the South Platte River (Figure 5).*"

Comment: Mean monthly data is not an adequate basis for analysis of effects on aquatic resources. The monthly time scale is not sufficient to determine changes on the aquatic resources. The EPA in its scoping letter (EPA letter page 2) recommended the following: "*The hydrologic analysis should be sufficiently detailed to provide the necessary information for the assessment of biological impacts. Monthly average discharge is usually insufficient for such analysis. At a minimum, wet, average, and dry year analysis should also be included*." There are large changes to hydrology for the action alternatives, which should be addressed by using daily hydrology for wet, average, and dry year types. This would allow the comparison on a biologically meaningful time scale. This analysis should be conducted and presented in an SDEIS and Revised Section 404(b)(1) Analysis.

ABRTR Section: 2.2.3 Instream Flow Incremental Methodology, page 40
Comment: The City agrees with the use of the Instream Flow Incremental Methodology (IFIM) and the Physical Habitat Simulation (PHABSIM) portion of that model. The study relied on existing data sets for the habitat simulations. Based on the methods described, only the existing Weighted Usable Area (WUA) data was used in the analysis. It does not appear that any ground-truthing of the existing cross section data was completed to determine applicability to the present day channel. All of the existing data sets were collected over 20 years ago and substantial changes may have occurred to the River within the City. In particular, the cross section data should have been reviewed to insure that the hydraulic simulations conducted in the mid-1980s were still representative of today's environment.

The PHABSIM data included cross sectional information that could be used to address impacts of changes in wetted area on benthic invertebrates. As noted earlier, the use of mean monthly flow data does not allow a biologically meaningful analysis of flow fluctuations on benthic fauna; however, the large changes in flows on a monthly basis seem to indicate that large fluctuations on a more frequent basis are possible.

ABRTR Section: 2.2.3 Instream Flow Incremental Methodology, page 40
Statement: "*We focused our effects analysis on the minimum habitat levels for each species/life stage. Therefore, we determined the minimum habitat level in a given year type (average, wet, and dry*)."

Comment: Minimum habitat level can influence population levels; but impacts on habitat levels cannot be adequately analyzed based on a single minimum habitat value for each year type, especially a single monthly value. Other factors such as frequency of occurrence are also important to aquatic populations. Additional interpretation of time of year should be addressed, as well as minimum habitat value. Time of year is important to determining the impact of changes in river flows on habitat. For most PHABSIM studies, the habitat suitability criteria are derived for moderate to low flows. Habitat use by the species of interest is typically variable on a seasonal basis. Habitat occupied during base flow is likely not the same habitat occupied during peak runoff. The analysis should

include an interpretation of a time series graph of the habitat for wet, average, and dry years and should be fully explained and presented in an SDEIS.

ABRTR Section: 3.2 Fish Populations, page 46
Comment: The fish occurrence data should be segmented by study reach to provide a basis for evaluating environmental consequences. While the list of species for the total study area is informative (Table 2, Page 46), the presence of species by river segment would provide more useful information, especially since the Cache La Poudre River is transitional from coldwater to warm-water within the study area. The historical data should be presented in the same format as the supplemental data collected in 2005.

ABRTR Section: 4.1.1. Upstream of Fort Collins, Effects Summary, page 71
Statement: *"The reductions in maximum flows during runoff in May, June, and July with the action alternatives would tend to increase habitat availability for brown and rainbow trout more than the reductions in winter flows would decrease habitat availability."*

Comment: This statement is confusing. It is illogical to compare impacts to trout from reduced peak flows with the impacts due to reduced winter flows. Furthermore, the assertion in the first half of the statement runs contrary to accepted ecological theory and the ABRTR should therefore provide supporting literature. Second, it is unusual to make a direct comparison between habitat at peak flow and habitat during winter flow, as habitat requirements are distinct for each season. Recent research on ecological flows has shown that the channel maintenance that occurs at peak flow is very important to long term habitat health (Bunn and Arthington, 2002, Fausch et al., et al., 2002, Rathburn et al., in press).

Additionally, the use of PHABSIM to evaluate peak flows should be secondary to the stream morphology analysis for peak flows. The habitat time series graphs do show that the minimum habitat occurs during runoff (Figures G-3 & G-6). These same graphs show winter habitat is reduced by NISP by approximately 20% or more for several months. The fact that the full channel is wet during peak flow and only a partial channel is wet at the base flow should be incorporated into the interpretation of impacts. The cross section data used from the previous studies with graphs of water surface versus discharge would depict the amount of wetted area available for fish habitat. The amount of wetted area is also important to the continued productivity for benthic invertebrates. The reduced area of wetted channel would provide less habitat for invertebrates and will negatively impact the biological community.

ABRTR Section: 4.1.2. Near Fort Collins, Effects Summary, page 77
Statement: *"The changes to channel morphology, the increased sedimentation, degraded water quality, and the greater occurrence of low flows would be detrimental to*

both fish and invertebrates. The adverse effects would result in lower abundance and fewer species of fish and invertebrates."

Comment: The City agrees with this statement. An SDEIS should study in detail the effects of lower dissolved oxygen levels and higher temperatures on fish and invertebrates as well as on trout habitat. The City does not agree with the following statement that concludes the paragraph:

ABRTR Section: 4.1.2. Near Fort Collins, Effects Summary, page 77
Statement: "*The minor adverse effects would not be more serious because, over time, these changes will happen gradually, and the fish and invertebrate communities would adapt to the new flow regime and channel morphology."*

Comment: A reduction in fish and invertebrate abundance and diversity can not be considered an "adaptation". There will be a reduction or elimination of biotic diversity due to degradation of stream conditions from NISP. The resulting loss of species should be considered a major adverse impact. The ABRTR presents a good summary of the loss of species over time. However, that gradual loss of species due to human induced changes to the Cache La Poudre should not be considered "natural" and must be put in context of the impact of the proposed action on the baseline (i.e. existing) aquatic fauna in the River. This misleading characterization must be corrected in an SDEIS.

ABRTR Section: 4.1.3 Fort Collins to Interstate 25, Effects Summary, page 83
Statement: "*The information from both the hydrology and PHABSIM simulation indicates that the action alternatives would provide substantially more habitat for fish and invertebrates than the baseline flow conditions …. However, the beneficial effect would be dampened by the adverse effects of slightly degraded water quality, channel narrowing and sedimentation.*"

Comment: This statement appears to argue that decreased peak flows and increased winter base flows would provide more habitat than the current flow regime. The City does not agree, however, that a reduction in spring flows of the magnitude predicted to result from NISP, which would result in additional sedimentation and channel narrowing (among other negative effects), would provide more aquatic habitat. Accumulation of sediment would change the environment for both invertebrates and fish, and possibly modify (negatively) the food chain. Further analysis in an SDEIS is needed to determine if the degree of sediment accumulation, water quality degradation, and channel narrowing would override the benefit of higher winter base flows.

ABRTR Section: 6. Mitigation, page 99
Comment: The ABRTR contains no discussion of avoiding or lessening losses to aquatic resources for the transitional reaches of the Cache La Poudre River. The mitigation, as proposed, does not address the loss of habitat and species complexity in the

River downstream of the Pleasant Valley and Lake Canal. The proposal to stock native fish in isolated, off-channel habitats would not constitute mitigation for losses in the primary channel. Isolated habitat without connection to the River for voluntary ingress and egress does not contribute to the riverine community. Further, these types of habitat were not quantified in the existing environment section to determine if these habitats are available, have permanent water of sufficient water quality to support reproducing population, or would be subject to avian and mammalian predation without adequate escape cover. Finally, the hypothesis that these stocked fish "may escape from these areas and recolonize the Cache La Poudre River" is highly unlikely given the reduction of peak flows. Out of channel peak flows would be required to inundate these isolated off-channel areas and allow fish to move out of the isolated areas.

5. Terrestrial Wildlife

5a. General comments

Riparian habitats in semiarid landscapes support a disproportionately high number of wildlife species. For example, 82% of all breeding birds in northern Colorado occur in riparian habitats while 51% of all species in the southwestern U.S. are obligate to riparian systems (Knopf et al., 1988, Knopf 1985). Furthermore, during migration, riparian habitats attract 10 to 14 times the number of birds compared to upland habitats (Stevens et al.1977, Hehnke and Stone, 1979). A large volume of peer reviewed research indicates the proposed alternative could cause short- and long-term negative changes to critical habitat components to wildlife including loss of mature cottonwood forests, lack of cottonwood recruitment, homogenization of habitats consisting of highly adapted species (weeds), and a subsequent reduced diversity of wildlife guilds. Because the City is heavily invested in over 1,400 acres of habitat along the Poudre River through Fort Collins, the maintenance and/or improvement of riparian habitat and conservation of the dependent wildlife within the riparian system are of paramount concern.

Analysis of wildlife in a riparian ecosystem depends on a "clear understanding of habitat requirements and the physical and biotic processes that create and maintain those habitats" (Askin, 2000, Baron et al., 2002, Skagen et al., 2005). Overall the DEIS does not adequately describe the wildlife resource along the Poudre River through Fort Collins. The DEIS also does not describe the direct and indirect impacts to wildlife resulting from the proposed action.

Due to the sparseness of data in this chapter and oversimplification of ecological theories, the project proponents have not met the minimum requirements outlined in the Section 404(b)(1) Guidelines to understand the terrestrial wildlife resource and predict project impacts. Although some information was gathered from other published sources, this effort was not thorough and was inadequate. Without the required data gathering and analysis, the Corps is not able to address the impacts from NISP in the manner required by NEPA and the Section 404(b)(1) Guidelines. This analysis should be conducted and presented in an SDEIS and Revised Section 404(b)(1) Analysis.

Only once was City of Fort Collins Natural Areas Staff consulted (for a one hour meeting) during the scoping period to discuss wildlife issues along the Poudre River through Fort Collins. At that time, City staff was not given clear information on the impacts of NISP to the flow regime when asked about the potential impact to wildlife (meeting in November 2006 with Stacy Antilla (ERO) with Rick Bachand and Karen Manci (City)). The proponent's consultants did not request any data from the City's Natural Areas Program.

The City has a wildlife species list for Poudre River Natural Areas (routinely available to the public) documenting 267 distinct species. This information was not included or considered in the DEIS. There is no evidence presented in the DEIS that suggests site specific surveys were conducted for species other than for a few select species of concern.

Fundamental conflicts exist within and between the DEIS and the Wildlife Technical Report (WTR) regarding basic elements of the project, severity and magnitude of impacts to wildlife and impacts to the wildlife habitat. Similar disconnects are present between the Biological Assessment (BA) and the WTR.

No information or discussion is provided on: species specific habitats, density and distribution, season of use, breeding vs. migratory habitat requirements, source versus sink populations, patch size, movement corridors, high versus low quality habitat, habitat juxtaposition, larger scale landscape issues, disproportionate loss of species, disproportionate habitat value, cascade of impacts due to reduced water quality and change in impacts to lower food chain species.

The following are specific examples of why the analysis of wildlife is inadequate:

1. The DEIS describes impacts to wildlife along the Poudre River only once, in a subsection entitled "Temporary Impacts." Contrary to the DEIS conclusion, changes to wildlife habitat are likely to be permanent and wide ranging. This is a fundamental issue, because Section 404 requires the Corps to give particular consideration to permanent impacts.
2. In the cursory description of wildlife in the riparian corridor there is a section dedicated to highlighting the importance of this area for waterfowl. The discussion never addresses the existence of neotropical migrant birds in the Poudre River riparian corridor.
   The WTR provides a brief and anecdotal description of the impacts to wildlife habitat, and then concludes: "*Although species diversity and abundance of riparian-dependent wildlife species could be reduced in localized areas, no major changes in species composition or distribution are likely.*" WTR Section 6.2.6 (page 45).
3. If species diversity and abundance are reduced then they should be quantified and characterized as a moderate or major adverse effect.

Without quantifying what wildlife will be impacted by the project, any proposed mitigation measures to address those impacts are speculative and essentially meaningless. Mitigation objectives must be measurable, and based on specific and quantified habitat components (shrub density, plant species composition etc) and wildlife components (species richness, nesting vs. migration habitat etc.) based on pre-construction (baseline) surveys. Without these data, there is no way to understand project impacts or the probability that mitigation measures would be targeted and successful. As a result, the Corps cannot comply with the requirements of NEPA or Section 404 without further analysis in an SDEIS and a Revised Section 404(b)(1) Analysis.

5b. Specific comments on the DEIS

DEIS Section: 3.14.11 Poudre-South Platte River Corridor Study Area, page 3-67
Statement: *"Wildlife species tolerant of human disturbance associated with riverine and riparian habitat likely occur in this study area. White-tailed deer winter range and concentration areas occur throughout the Poudre-South Platte River corridor study area (Figure 3-15). The Poudre-South Platte River corridor study area provides breeding, wintering, and migratory habitat for a variety of waterfowl species. According to Andrews and Righter (1992), 16 species of ducks are described as common to abundant in the Poudre-South Platte drainage (including the study area) during migration, breeding, and winter. Several other duck species are rare to uncommon, but regularly occur in the drainage."*

Comment: This description of the wildlife resource does not adequately capture the value of the riparian corridor to wildlife and the species currently utilizing this habitat. Riparian ecosystems, especially those in semi-arid landscapes, support a disproportionate number of species compared to the surrounding landscape (Brode and Bury, 1984, Finch and Wang, 2000, Skagen et al., 1998, Skagen et al., 2005). In addition to the suite of obligate riparian species, many upland species depend on riparian habitats for forage, cover and for migrating corridors. The statement above seems to indicate the Poudre River currently hosts only "*species tolerant of human disturbance, white-tailed deer and waterfowl*."

In fact, the study area actually hosts a set of species far exceeding this description. The City is deeply concerned by this misrepresentation of Poudre River habitat value. Below is a list of species that have been observed within the City-owned Poudre River Natural Areas (which is limited to only 10 miles of the most urbanized segment of the Poudre River). This list of **267 species** provides a much better portrayal of the exceptional value of the riparian corridor to wildlife and explains why the health of the riparian habitat is of utmost importance to the City.

****

Animals Observed on Poudre River Natural Areas, 1974-2008

Species: U = unusual; I = Introduced (to North America for Birds; to Fort Collins area for other species); FT = Federal Threatened; FE = Federal Endangered; ST = Colorado Threatened; SC = Colorado Species of Concern.

Occurrence: X = recorded on site; XN = nests on site; Xn = attempted to nest (unsuccessful); XD = dens on site.

Sources: Compiled from observations by local naturalists, researchers, CSU and Natural Areas Program volunteers, Colorado Division of Wildlife, Colorado Field Ornithologists' reports, and Natural Areas Program staff.

In sum, given the valuable role the riparian system serves in supporting regional wildlife diversity, the failure to objectively and methodically describe this wildlife resource is of significant concern to the City. Consequently, the City wishes to emphasize, as stated above, that this issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis. *See* Section 404(b)(1) Guidelines Section 230.32. *See also* Section II.4b of these Comments.

DEIS Section: 3.16.11 Species of Concern, Poudre-South Platte River Corridor Study Area, page 3-90
Statement: *3.16.11.1.1 Preble's Meadow Jumping Mouse*
Known occupied Preble's habitat in the study areas is shown on Figure 3-16. Preble's is not known to occur on the Cache la Poudre River downstream of Fort Collins or on the South Platte River downstream of its confluence with the Poudre River.

Comment: A field inventory (trapping effort) should be conducted to verify that Preble's does not occur within the Poudre River drainage.

DEIS Section: 4.2.1.1 Effects Common to All Action Alternatives, Changes to Poudre River Flows, page 4-6
Statement: "*Flow reductions are likely to have significant localized effects on…riparian resources."*

Comment: If this statement is true, then the riparian resources, including utilization by wildlife, must be properly evaluated in an SDEIS and Revised 404(b)(1) Analysis. *See* Section 404(b)(1) Guidelines Section 230.32. Furthermore, if this statement is true then there is a direct conflict between this statement and Table 4-6, which appears in the DEIS a few pages later and summarizes the "Distinguishing Effects of the Alternatives". Table 4-6 compares the proposed action with the no action alternative and states there is "No Distinguishing Effect" for all wildlife categories, except for Threatened and Endangered species. This claim, based on no field data or analysis and the failure to extrapolate habitat impacts to wildlife impacts, is of great concern and also must be subjected to further environmental review to meet the requirements applicable to the DEIS and Section 404(b)(1) Analysis.

DEIS Section: 4.14.3.2.2 Temporary Disturbances, Riparian Habitat along the Cache la Poudre and South Platte Rivers, page 4-55
Statement: "*However, a reduction in the infrequently occurring overbank flows may affect the periodic disturbance of the riparian zone that can aid in creating new habitat for riparian vegetation establishment and rejuvenation of the riparian zone."*

Comment: It is incorrect to treat impacts to the wildlife within the riparian corridor of the Poudre River as temporary by placing them in the Temporary Disturbances section.

In fact, nowhere else in the DEIS or supporting documents are the impacts to the riparian corridor (and wildlife dependent on it) described as temporary. Despite the conflicting conclusions regarding riparian habitat throughout the documents, the one consistent conclusion in these documents is that there will be a long-term effect due to reduced overbank flooding and consequent reduced capacity for cottonwood regeneration. This is not a temporary impact, and the effect it has on wildlife also would not be temporary. As discussed in Part II, this is particularly important, because Section 404 requires the Corps to pay particular attention to impacts that would be permanent.

Furthermore, the Scoping Report for NISP clearly identifies the Poudre River riparian corridor as an affected environment and defines both Wildlife and Riparian resources as "significant general categories" to become the focus of the DEIS. Discussing the impacts to wildlife solely in the Temporary Disturbances section of the DEIS is inconsistent with the Scoping Report.

Another key point about this citation from DEIS page 4-55 is that it understates and incorrectly characterizes impacts to wildlife along the Poudre River. Many studies show that the dewatering of a river could cause steady (linear) degradation of the habitat. These adverse effects include; loss of herbaceous and/or shrubby species and physiologic stress to larger woody species over the short term (see comments to the Vegetation Technical Report). Landscape level changes such as declines of cottonwoods along entire river segments may be expected over the long-term. Because the Poudre River is already in a compromised state (lowered resistance and resilience) the probability that future flow reductions will cause these impacts is increased (City of Fort Collins, 2008). Associated impacts to wildlife may be wide-ranging and deserve analysis on both a local and a regional scale.

Finally, while these changes may be described as linear, the potential for non-linear (and less predictable) change must also be considered. Significant reduction of peak flows could potentially cause the Poudre River to cross a threshold and respond in a non-linear manner that would result in much greater loss of ecological values, ecosystem complexity, and physical and ecological function.

DEIS Section: 4.14.3.2.2 Temporary Disturbances, Riparian Habitat along the Cache la Poudre and South Platte Rivers, page 4-55
Statement: *"As described in the Wildlife Technical Report (ERO 2008c), the flow reductions are not expected to cause losses of riparian and wetland habitat. However, a reduction in the infrequently occurring overbank flows may affect the periodic disturbance of the riparian zone that can aid in creating new habitat for riparian vegetation establishment and rejuvenation of the riparian zone."*

Comment: Within the Wildlife Technical Report (WTR) there are opposing conclusions about impacts to wildlife along the Poudre River. For example:

WTR Section: 6.2.6, page 45
Statement: *"Although species diversity and abundance of riparian-dependent wildlife species could be reduced in localized areas, no major changes in species composition or distribution are likely."*

And;

WTR Section: 7.2.1, page 65
Statement: *"Many species of birds, mammals, reptiles, and amphibians dependent on these (riparian and wetland) habitats would in turn be affected by these changes."*

The public cannot assess the impacts to wildlife when the WTR effectively cancels out its own conclusions. This issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

DEIS Section: 4.14.5 Mitigation
Statement: *The District and the Corps will coordinate with CDOW regarding mitigation of impacts to wildlife and wildlife habitat.*

Comment: This statement provides no information about an actual mitigation plan, nor does it address impacts sufficiently to meet the requirements of the Section 404(b)(1) Guidelines. Without quantifying what wildlife will be impacted by the project, any proposed mitigation is speculative and essentially meaningless. Mitigation goals must be based on specific and quantified habitat components (shrub density, plant species composition etc) and wildlife components (species richness, nesting vs. migration habitat etc.) based on pre-construction surveys. The Corps cannot defer its analysis of impacts and how they must be addressed until beyond the Section 404 and NEPA process. Without these data, there is no way to understand project impacts or to evaluate the proper responses or requirements to address them. This assessment should be completed and presented in an SDEIS.

DEIS Section: 5.4.1. Wildlife (Mitigation)
Comment: see comments for Section 4.14.5

DEIS Appendix B: Consultation with U.S. Fish and Wildlife Service Biological Assessment and Biological Opinion
Comment: Although the US Fish and Wildlife Service has provided a "final" biological opinion on a proposed action, that opinion appears premature as no decision on a final action has been made. A Biological Opinion is traditionally issued with a Record of Decision, not along with the DEIS. In addition, due to omissions, deficiencies and inadequacies throughout the DEIS, the Biological Assessment (BA) is substantively

premature. The BA must be reevaluated after an SDEIS that includes improved data and analyses regarding all categories of impacts from NISP relevant to wildlife, including trapping of the Preble's Meadow Jumping Mouse along the Poudre River, improved analysis of the effects of the proposed action on riparian vegetation and invasive species. Consultation should be reinitiated once a final decision is made given that it may differ from the original proposed action.

5c. Comments on Wildlife Technical Report (WTR)

WTR Section: 5.1 Big Game, page 21 AND Section 6.3.1, page 46
Statement: *"white-tailed deer are most often seen in riparian areas bordering large streams and river. …white-tailed deer will move seasonally up and downriver corridors in small numbers….white-tailed deer concentration areas are considered critical habitat for white-tailed deer and occur in corridors of riparian habitat that support higher populations of white-tailed deer or serve as travel corridors…Numerous mule and white-tailed deer crossing areas occur near the SPWCP forebay and diversion study area, highlighting the importance of the Poudre and South-Platte river corridors as deer habitat."*

Comment: Despite the direct identification (in this statement from Section 5.1) of the importance of river corridors to deer, Section 6.3.1 of the WTR makes no mention of impacts to deer due to changes to the riparian habitat such as a decline in woody cover.

WTR Section: 5.2. Raptors, page 30 and Section 6.3.2., page 49
Comment: Nests were identified based on size, nest materials, structure, location etc. Little effort was made to document nest use or to identify species using the nest. Also, little thought was given to the use of nests by different species over time. Surveys appeared to have been conducted late in the breeding season (July 8 or later) and only one year of field observations were used for each study location. Based on the data provided, little is known about raptor resources in the area. Surveys were inappropriately limited to Reservoir sites and the Highway 287 realignment and excluded the Poudre River.

WTR Section: 5.2.2 Migratory Birds, and Section 6.3.2, page 49
Statement: *"Based on a study conducted by Hopper (1968), the Poudre-South Platte study area lies within one of the four most important waterfowl regions in Colorado, the South Platte River drainage. Spring (May) surveys established in the 1950s and conducted until the 1990s indicated that more than 20,000 migrant or locally breeding ducks were present in this area during the survey period (Gammonley 2008). Much higher numbers of ducks use the area throughout the spring and fall migration periods (Ibid). According to Andrews and Righter (1992), 16 species of ducks are described as common to abundant in the Poudre-South Platte drainage (including the study area)*

during migration, breeding, and/or winter; and several other duck species are rare to uncommon, but regularly occur in the drainage. Dabbling ducks such as mallards, green-winged teal, blue-winged teal, American widgeon, gadwall, northern pintail, and northern shoveler are most common along the Poudre River drainage from the foothills to the South Platte confluence. These species not only use the river and associated streams, but rely heavily on small wetlands and sloughs. Wood ducks and hooded mergansers, both riparian-dependent species, are increasing in numbers in this area (Ibid.). Resident and migrant populations of Canada geese have increased in the South Platte River drainage. Andrews and Righter (1992) reported that about 1,200 Canada geese breed on the plains near the northeastern foothills, including the Poudre River corridor, and that more than 50,000 geese winter in this area."

Comment: Given this characterization of the importance of the Poudre River to waterfowl, it is reasonable to expect that a data-driven, science-based methodology would be used to assess and quantify impacts to waterfowl that would result from the significant reductions in river flows NISP is predicted to cause. No such effort was made. Such an analysis must be conducted and presented in an SDEIS.

With regard to all other migratory birds it appears little or no site specific data were gathered. Species identified were based on broad habitat categories and listed as species expected to occur. While species based on habitat affinities are a good start, without site specific information describing density, breeding populations etc, it is difficult to determine impacts from the project. Also, species listed are minimal and are far from inclusive. In contrast, the City Natural Areas program maintains a list of species that contains 267 entries. *See* comments on DEIS Section 3.14.11 in Section IV.5b of these Comments. Based on information provided in the DEIS, virtually nothing is known about the site-specific attributes of the avifauna.

The Poudre River is extremely important to migrating songbirds. It is unclear why this section titled "Migratory Birds" did not include the neotropical migrants along the Poudre River riparian corridor. In the table shown below, birds found within City Natural Areas along the Poudre River account for two-thirds of the Fort Collins total bird diversity. This table also shows that the Poudre River through Fort Collins closely compares to major national parks as measured by bird diversity.

Area	# Acres	# Bird Species
Poudre River City-owned Natural Areas	**1,423**	**223**
Fort Collins Growth Management Area	~48,000	353
Yellowstone National Park, WY	2.2 million	311
Everglades National Park, FL	1.5 million	310
Pawnee National Grassland, CO	193,060	301
Rocky Mountain National Park, CO	265,726	280
Acadia National Park, ME	35,000	273
Mesa Verde National Park, CO	52,122	186
Bryce Canyon National Park, UT	35,835	171
Isle Royale National Park, MN	571,790	168
Denali National Park, AK	6 million	165

In sum, this issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 5.3. Amphibians and Reptiles and Section 6.3.3, page 53
Statement: *"Many amphibians inhabit areas near wetlands and areas containing a water source throughout the year …wetter habitats tend to support a higher diversity of reptiles"*

Comment: No surveys were conducted to determine species richness, density or distribution. Impacts are discussed relative to habitat (wetland) loss due to reservoir and other construction. No impacts are discussed relative to water loss, wetland loss, or habitat modification from reductions in flows in the Poudre River predicted from NISP.

If, as stated in this report, 75 acres of wetlands will be lost along the Poudre River (above Interstate 25), surveys for reptiles and amphibians should have been conducted to quantify the expected loss of species diversity and abundance. This is a significant omission and must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 6.2.6, Riparian Habitat…, page 41
Statement: *"The effects of changes in stream flows on wildlife were evaluated based on the analysis of impacts to riparian and wetland habitat, described in detail in the Vegetation Resources Technical Report (ERO 2008b), which were assessed based on an analysis of potential changes in stream morphology, ground water, and stream stage as discussed in the Water Resources Technical Report (HDR 2007) and River Morphology and Sediment Transport Technical Report (Anderson 2008). Methods and results of these analyses are summarized below."*

Comment: The quoted conclusion regarding riparian and wetland habitat along the Poudre River is not supported by the scientific literature, nor is it supported by field level data. Furthermore, it appears to be based on a profoundly incorrect river-flow data set.

Within the WTR there are conflicting statements regarding the impacts to riparian habitat. The conflict undermines the analysis of resources dependant on riparian habitat. Terrestrial wildlife relies on the composition and structure of riparian vegetation. Immediately below are just two examples of conflicting statements about impacts to wildlife habitat *within* the WTR:

WTR Section: 6.2.6, page 43
Statement: "*The reductions in streamflows on the Poudre and South Platte rivers associated with the action alternatives are not anticipated to cause a loss of riparian and/or wetland vegetation."*

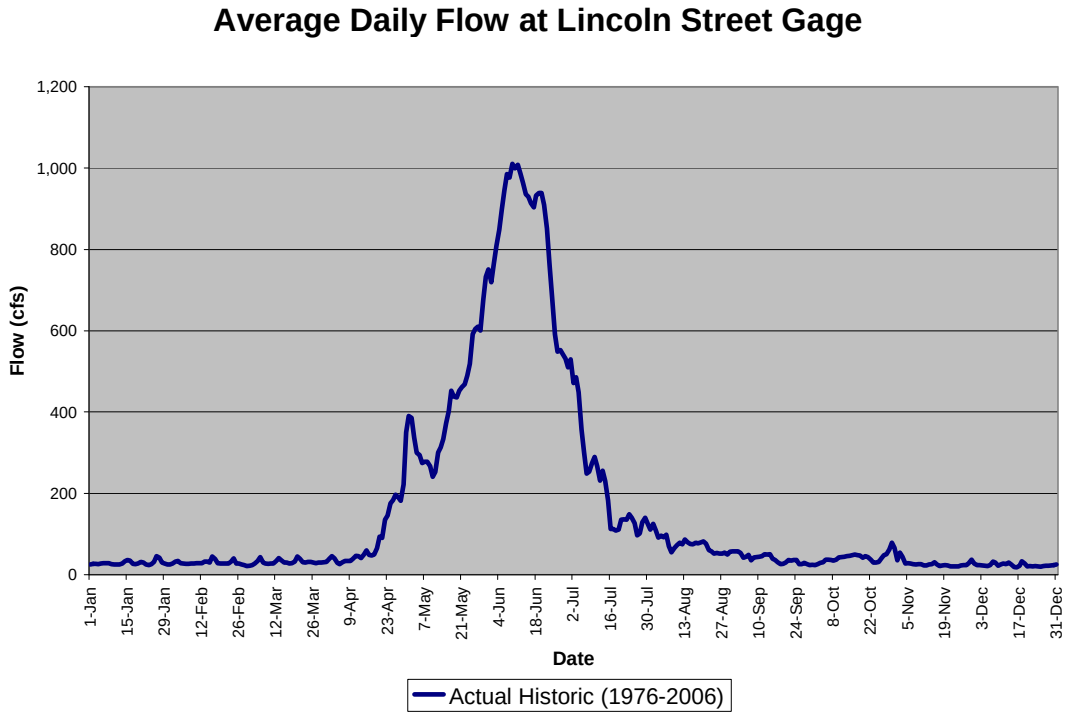
And;

WTR Section: 7.2.1., page 65
Statement: "*The action alternatives would likely result in changes to and losses of riparian and wetland vegetation, especially herbaceous vegetation, in sensitive riparian areas along the Poudre River corridor."*

These fundamental conflicts must be resolved and an improved analysis presented in an SDEIS.

WTR Section: 6.2.6, Riparian Habitat…, page 42
Statement: *"... Because of human alterations… there has been a change in flow regime from one characterized by large spring runoff with low flows the remainder of the year, to a flow regime that is characterized by moderate flows spread throughout the year."*

Comment: This statement is incorrect. While there have been changes to the flow regime of the Poudre River, the current flow regime is still characterized by a spring snow-melt dominated flow regime (see graph of actual historic flows below). This information is readily available to the public from a variety of sources. The rest of the year is characterized by fairly low to very low flows. Understanding the current flow regime is essential to assessing the potential impacts due to predicted reduction (up to 71%) of spring peak flows from NISP. The DEIS must make accurate statements about the existing conditions to adequately identify impacts of the proposed action and to address those impacts as required in the Section 404(b)(1) Guidelines. *See* Section II.3 of these Comments.



Graph assembled from publicly available data on the Internet at: http://waterdata.usgs.gov/CO/nwis/uv?06752260

WTR Section: 6.2.6, Cache la Poudre Upstream of I-25…, page 42
Statement: *"Assuming that the changes discussed above will occur in only portions of these 301 acres, about 89 acres of the sensitive areas may change over time. Of these 89 acres, it is estimated that about 75 acres of wetlands would be affected."*

Comment: The author does not state how the values of 89 and 75 acres values were determined other than references to the terms "assuming" and "estimated". The stated numerical values are not explained in the WTR or the Vegetation Technical Report (VTR). Assumptions and estimations are not adequate methods for analysis of wetlands impacts. An adequate DEIS and Section 404(b)(1) Analysis would indicate whether these were wetlands identified using the Corps' method for identifying jurisdictional wetlands; this is not done. It appears no effort was made to identify jurisdictional wetlands on the Fort Collins Reach of the Poudre River. This issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 6.2.6 Cache la Poudre Upstream of I-25…, page 42
Statement: *"Through the City of Fort Collins, it appears that the flow changes that would occur under the action alternatives would likely affect stream morphology,*

because of large reductions in flow during spring runoff in wet and average years. Some potential changes include channel narrowing, greater sediment deposition and less sediment flushing, vegetation encroachment into the channel, increase in the size of inchannel islands, flow obstruction, and bank erosion (ERO 2008d)."

Comment: The referenced study in this passage in the WTR - ERO 2008d - refers to the South Platte River near Kersey in the River Morphology and Sediment Transfer Technical Report (RMSTTR) and, therefore, is not relevant to the Fort Collins segment of the River.

If these changes are expected to occur, however, it is reasonable to expect this study area to be included in the discussion of Alternative 2 in WTR Section 6.3. Throughout Section 6.3, there is no mention of the wildlife habitat or affected species as a result of Alternative 2.

WTR Section: 6.2.6 Cache la Poudre Upstream of I-25…, page 44
Statement: *"Effects to sensitive riparian areas associated with streamflow changes are anticipated to be localized and subtle…habitat changes will likely occur slowly and subtly over many years…."*

Comment: There is little, if any, evidence, to support the concept that the effect to herbaceous wetlands, an important habitat for much wildlife, would be subtle or slow. In fact, with regard to this topic the Biological Assessment (BA) states (page 30): "*changes in groundwater levels...would likely remove the supportive hydrology and the wetlands would no longer be wetlands...*" Specifically for the Lincoln Gage, the BA states (page 32): "*These changes in mean monthly stream stage in sensitive riparian areas …would affect herbaceous wetland vegetation (and therefore scrub-shrub wetlands).*" This issue must be analyzed and addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 6.2.6 Cache la Poudre Upstream of I-25…, page 44
Statement: *"…it is estimated about 75 acres of wetlands would be affected."*

Comment: It is not stated and not apparent how this numerical value was derived. If this statement is true, these wetlands should have been 1) delineated in the field according to the Corps' method; 2) surveyed methodically for Threatened and Endangered Species or species of concern; and 3) evaluated as habitat for all local wildlife. This issue must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 6.3
General Comment: There is no mention within this entire WTR section of the impacts to wildlife in the riparian corridor. This is a serious procedural flaw because:

1) the Scoping Report states the Poudre River riparian corridor is an "affected environment" and identifies Riparian Resources and Wildlife as "Significant General Categories"; and
2) the Section 404(b) Guidelines require *appropriate factual determinations, evaluations, and tests on the physical*…for the affected resources (Section 230.11 of 404(b) Guidelines). The WTR states that: *"Many species of birds, mammals, reptiles, and amphibians dependent on these habitats would in turn be affected by these changes"* (WTR Section 7.2.1, page 65). Therefore compliance with the Section 404(b)(1) Guidelines requires that the participants evaluate effects to "Other wildlife" and the possible loss of values to other wildlife. *See* Section 404(b)(1) Guidelines Section 230.32 (a) and (b). The anecdotal level analysis provided in WTR Section 6.2.6 does not come close to fulfilling this requirement.

Specifically Section 230.32 (b) of the Section 404(b)(1) Guidelines states:

"Possible loss of values: The discharge of dredged or fill material can result in the loss or change of breeding and nesting areas, escape cover, travel corridors, and preferred food sources for resident and transient wildlife species associated with the aquatic ecosystem. These adverse impacts upon wildlife habitat may result from changes in water levels, water flow and circulation, salinity, chemical content, and substrate characteristics and elevation. ….Changes in such physical and chemical factors of the environment may favor the introduction of undesirable plant and animal species at the expense of resident species and communities. In some aquatic environments lowering plant and animal species diversity may disrupt the normal functions of the ecosystem and lead to reductions in overall biological productivity."

Most if not all of the habitat components or ecosystem attributes mentioned in this paragraph (above) may be affected within the Poudre River study area by the proposed action. This must be addressed in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 6.3.4. Other Wildlife Species
Statement: *"Small and large mammals associated with affected vegetation types described in Section 6.3.2 would be directly affected by alternative 2."*

Comment: WTR Section 6.3.2 does not mention the Poudre River study area at all, requiring reassessment in an SDEIS and Revised Section 404(b)(1) Analysis.

WTR Section: 7.2.1. Mitigation, page 65
Statement: *"The action alternatives would likely result in changes to and losses of riparian and wetland vegetation, especially herbaceous vegetation, in sensitive riparian areas along the Poudre River corridor. Many species of birds, mammals, reptiles, and amphibians dependent on these habitats would in turn be affected by these changes. Most*

of the riparian areas potentially sensitive to reduced flows and stream stage are designated as natural areas by the City of Fort Collins. Mitigation measures under consideration at this time are:

• Work with the City of Fort Collins to create and restore habitat by lowering the surface elevation of selected riparian areas to provide a supportive hydrology with the future flow reductions.
• Work with aggregate mines to reclaim these mines as riparian areas.
• Construct check structures in the Poudre River that would raise stream stage to compensate for low stream flows and stages."

Comment: This report fails to discuss the expected impacts to migratory birds, amphibians, raptors, reptiles and mammals. This makes it difficult, in not impossible, to craft adequate measures to address the impacts to wildlife from NISP. Furthermore, the suggested mitigation measures are stated in vague terms, with no binding or enforceable commitments of any kind. Finally, this section asserts conclusions that are directly contrary to other conclusions in the report. Therefore, it is not possible to discuss the proposed mitigation until an SDEIS is prepared that provides consistent conclusions and analysis based on sufficient and correct data. *See* comments on DEIS Section 4.14.5 in Section IV.5b, above.

6. Air Quality and Climate Change

6a. General comments

The scientific literature is now replete with admonitions for water managers regarding the need to include the potential effects of climate in water resource planning (Milly, et. Al, 2008). For example, Stewart el al. (2005) predict that "almost everywhere in western North America, a 10% - 50% decrease in the spring-summer streamflow fractions will accentuate the typical seasonal summer drought with important consequences for warm-season supplies, ecosystems, and wildfire risks." Regonda and others (2005) state that "if the trends in temperature, snowfall, and streamflow demonstrated in this paper persist and even intensify, changes in water management practices will be necessary to adapt to the altered hydrologic regime." As evidenced by many studies published since 2000, the specific concept of rising regional temperatures has been used to explain statistically significant trends and patterns in hydrologic response at basin scales relevant to water management in the Mountain West.

Many of these effects will be further affected by changes in the vegetation and structure of the Poudre River watershed. The near certainty of pine beetle infestation and more catastrophic forest fires in the next decade and beyond suggests that the next fifty years in the Poudre watershed will be significantly different than the 50 years modeled for the DEIS and on which all of the predictions of NISP impacts are based. Pine beetle and fire

effects on the forests will also influence the timing and amounts of runoff from the watershed and, thus, the water available for diversion to Glade, the water remaining in the Poudre and the overall water quality.

Having acknowledged the reasonable foreseeability of climate impacts on stream flow, the DEIS proceeds to ignore it, even though the fundamental basis for the project and its impacts would be profoundly influenced by climate change. The fact that uncertainty regarding the precise degree and effects of climate change exists does not excuse the Corps from analyzing this critical issue. "NEPA prohibits uninformed agency action." *Robertson v. Methow Valley Citizens Council,* 490 U.S. 332, 351, (1989). ''The procedures included in § 102 of NEPA are not ends in themselves. They are intended to be 'action forcing.' The unequivocal intent of NEPA is to require agencies to consider and give effect to the environmental goals set forth in the Act, not just to file detailed impact studies which will fill governmental archives.'' *Envtl. Def. Fund, Inc. v. Corps of Eng'rs of the U.S. Army,* 470 F.2d 289, 298 (8th Cir.1972) (citation omitted).

"The impact of greenhouse gas emissions on climate change is precisely the kind of cumulative impacts analysis that NEPA requires agencies to conduct." *Center for Biological Diversity v. NHTSA*, 508 F.3d 508 (9th Cir. 2007). Indeed, the United States Supreme Court has noted that the "harms associated with climate change are serious and well recognized." *Massachusetts v. EPA*, 549 U.S. ___, 127 S.Ct. 1438, slip op. at 18 (2007). The Court noted, in particular, the likelihood of a "significant reduction in water storage in winter snowpack in mountainous regions with direct and important economic consequences." *Id.* The Supreme Court also admonished the EPA that it could not "avoid its statutory obligation by noting the uncertainty surrounding various features of climate change…"[12] *Id.* at 31. The same reasoning applies to the Corps' obligations under both the Clean Water Act and NEPA.

The Council on Environmental Quality (CEQ) regulations that govern the conduct of environmental impact review make clear that agencies have an obligation to develop information that is necessary to a reasoned choice among alternatives (including the no-action alternative). 40 C.F.R. § 1502.22(a). Even if it cannot reasonably obtain such critical evidence, it must at least assess the significance of the missing information, provide a summary of the existing scientific evidence, and provide an evaluation of such impacts based upon theoretical approaches or research methods generally accepted in the scientific community. *Id.* at § 1502.22(b). CEQ has stressed the importance of addressing even uncertain effects in its Forty Most Asked Questions that provide guidance on the implementation of its NEPA regulations:

> [I]n the ordinary course of business, people do make judgments based upon reasonably foreseeable occurrences. . . . The agency has the responsibility to make

[12] The Supreme Court also attached "considerable significance to EPA's 'agree[ment] with the President that 'we must address the issue of global climate change,'" 68 Fed.Reg. 52929 (quoting remarks announcing Clear Skies and Global Climate Incentives, 2002 Public Papers of George W. Bush, Vol. 1, Feb. 14, p. 227 (2004). *Id.* at ___.

> an informed judgment, and to estimate future impacts on that basis, especially if trends are ascertainable . . . . The agency cannot ignore these uncertain but probable, effects of its decisions.

46 Fed. Reg. at 18031. Climate issues clearly fall within this category of reasonably foreseeable effects that affect the underlying purpose and impacts of the proposed action. Indeed, the National Academies of Science – in a joint statement with national science academies from other leading countries – has stressed that "[t]he scientific understanding of climate change is now sufficiently clear to justify nations taking prompt action…" *National Academies of Science, Joint Science Academies' Statement: Global Response to Climate Change*, available at http://nationalacademies.org/onpi/06072005.pdf.

The DEIS does not even take first steps towards addressing these climate issues. The purpose and need identified for this project hinges on providing a certain firm yield for NISP participants through 2050. The DEIS then assesses whether the project and certain alternatives would provide this firm yield (along with other project impacts) through 2050 using a purely retrospective data set (from 1949-1999). It is unreasonable to rely solely on a retrospective data set with no consideration of the effects of climate where the scientific evidence makes clear that future conditions will be different. *See* National Research Council, *Air Quality Management in the United States* at 234 (2004) (available at http://www.nap.edu/catalog/10728.html) (the "general consensus within the scientific community is that this warming trend will continue or even accelerate in the coming decades"). *See e.g*., Milly, et. al (2008).

The DEIS further ignores the most recent seven years of data, including serious drought, even though these years may be more representative of future conditions than the data set the DEIS used. In light of this past seven years of data and the overwhelming evidence that climate change will significantly affect water flows, the Corps cannot reasonably assume that the next fifty years will be like the period from 1949-99 and not include periods like 2000-2007. "Projected changes in runoff during the multidecade lifetime of major water infrastructure projects begun now are large enough to push beyond the range of historical behaviors." *Id.*

In other words, the Corps cannot assume that there is stationarity in the climatic and hydrological trends in the face of overwhelming evidence to the contrary (Milly, *et al.*, 2008). It is essential for decision makers to have information regarding the potential effects of climate trends on the firm yield of the project, the cumulative effects of the project on changing river flows, the need for acquisition of additional agricultural water for municipal use, and similar information. The DEIS already shows that the NISP project would be able to divert flows in only a handful of years in every decade based on the older historical regime. Changes in climate can be expected to further reduce this ability to divert, reducing firm yield significantly, requiring more agricultural dry-ups in the action alternatives and massively increasing the cost per acre foot for participants.

Despite uncertainty in the combined effects of future temperature and precipitation changes in the region, there is general consensus that there are substantial risks of altered annual runoff timing, increased interannual variability, and reduced runoff. There are scientifically accepted methods for using the current trajectory of streamflow behavior and a weight of scientific evidence to identify a reasonable probabilistic envelope depicting how regional streamflow could change over the coming decades. *See, e.g.*, Milly (2008) ("Methods for estimating model parameters can be developed to combine historical and paleohydrologic measurements with projections of multiple climate models, driven by multiple climate forcing scenarios."). Such an envelope can be used in selecting appropriate sensitivity factors for modeling purposes. *Id.* ("Projections of runoff changes are bolstered by the recently demonstrated retrodictive skill of climate models.). For example, the City of Boulder has been conducting sensitivity analyses of the effects of a range of climate scenarios on water supply and flows, an approach that could be readily conducted for NISP. *See*, City of Boulder, Lee Rozlaklis, Presentation to SWMP Community Study Group (Nov. 27, 2007) (available at http://www.ci.boulder.co.us/files/csg_nov_27_presentation_wip_revised_on_site.pdf); City of Boulder, Source Water Master Plan Water Availability Executive Summary (Nov. 2007) (available at http://www.ci.boulder.co.us/files/Utilities/Projects/source_water_mp/swmp_csg_mtg2.pdf). Other water suppliers in the region are also evaluating assessing or planning to assess the effects of climate on water supplies and flows. *See e.g., Denver Water*, *Comprehensive Annual Financial Report* at I-20 to I-21 (Dec. 31, 2007) (available at http://www.water.denver.co.gov/financialinfo/annualreport/DW_AR2007.pdf).[14]

Such sensitivity analyses are necessary to avoid uninformed agency action, as required both by NEPA and the Clean Water Act. The information and methodologies are reasonably available and supported by sound science. Indeed, assuming blindly -- and against the scientific record of the last decade -- that the future will be the same as the period starting in 1949 without any additional analysis lacks scientific merit. An SDEIS must include new MODSIM and other analyses with appropriate sensitivity analyses that reflect current trends in climate change and a reasonable range of effects predicted by climate models. The Boulder approach and other ongoing efforts can provide useful guidance and approaches.

Finally, an SDEIS must correct the DEIS's failure to provide any information about the effects of the proposed project on climate. For example, the DEIS should evaluate how many greenhouse gases are produced through the large scale pumping contemplated in the NISP project, as compared to other alternatives including no action.

---

[14] Denver Water has conducted sensitivity analyses for its system that used two different climate scenarios. Under one scenario with a two degree increase in temperature, average streamflows and Denver Water supply would drop by seven percent. Under the other scenario with a five degree change, average stream flows would drop 19 percent and Denver Water's supply by 14 percent. *Id.* These types of changes would have a large impact on the firm yield assumptions and streamflow impacts of NISP.

6b. Specific Comments on DEIS

DEIS Section: 3.25 Air Quality, page 3-127
Statement: *"As of November 20, 2007, the areas in the vicinity of the proposed Glade and Galeton reservoirs have been designated as nonattainment areas for ozone. However, air quality is currently not an issue in these areas."*

Comment: The cited conclusion is cavalier, unsupported and completely wrong. The fact that the proposed reservoir sites are in an area designated by the Environmental Protection Agency as nonattainment for the ozone standard is conclusive evidence that air quality is an issue in these areas, because ozone from elsewhere in the nonattainment area can affect these sites and because emissions of ozone precursors at these locations can affect ozone levels elsewhere in the nonattainment area. Thus, air quality is a very important issue that deserves serious treatment instead of the trivial dismissal it receives in the DEIS. Indeed, the EPA included Larimer County within the nonattainment area because of its concerns that emissions from within the county contributed to Denver-area ozone levels. These issues have become yet more challenging with EPA's tightening of the 8-hour ozone standard earlier this year. While ozone levels in Ft. Collins have not exceeded the new ozone standard based on the regulatory three-year average, annual readings have risen above the standard. *E.g.*, Larimer County, Compass of Larimer County (available at https://www.co.larimer.co.us/compass/airquality_env_quality.htm#tables). Further, nearby monitoring in Rocky Mountain National Park shows that ozone levels are above the new standard.

Section 3.25 needs to provide more analysis regarding the effects and nature of ozone as a powerful oxidant that can cause respiratory harm in humans, damage to vegetation, injury to materials and other effects. The section also needs to include both the 1997 and 2008 National Ambient Air Quality Standards for ozone and a description of what the standards mean. The section should also contain discussion about air quality monitoring in the nonattainment area. The section should describe the types of emissions and their sources that contribute to ground-level ozone, including the combustion sources that would be associated with construction of the project and generation of electricity for the project's massive pumping needs. Finally, the Section needs to describe both the transportation and general conformity rules (40 C.F.R. Part 93), including the *de minimis* standards applicable to the project area.

DEIS Section: 4.25.2 Air Quality, page 4-96
Statement: *"All of the alternatives would cause short-term increased exhaust emissions associated with construction vehicles (employee, delivery and heavy-duty equipment). … These emissions are expected to be within conformity levels."*

Comment: The statements and conclusions drawn in this section are completely unsupported and inadequate to comply with NEPA or the Clean Air Act. The section does not identify the conformity standards that apply or the basis for its conclusion that emissions would be below the *de minimis* thresholds of the general conformity rule. As a result, the DEIS is inadequate both under NEPA and the Clean Air Act. The construction activities proposed under any of the action alternatives are massive and would entail significant emissions from construction activities (including on-site earth moving, materials and fill hauling, and concrete hauling and placement equipment). Large new contributions to ozone precursor emissions are of considerable concern because the entire nonattainment area is struggling to meet both the 1997 and 2008 ozone standards, which have been determined by EPA to be requisite for human health.

The Glade Dam itself would involve the placement and construction of earth, rock and concrete almost a mile long and almost 300 feet high, along with forebay and other improvements. In addition, construction would include the Poudre Valley Canal Upgrades, pump stations, the Munroe Canal Bypass, the highway relocation, and the Glade-Horsetooth Pipeline. Galeton Reservoir would involve an almost-two-mile dam 60 feet high and other related facilities. All of these efforts would involve large numbers of emitting vehicles and equipment for considerable periods of time.

Because the DEIS makes no commitments for any use of low-emissions technology, it must be assumed that all of this work would be conducted with generally available diesel-powered equipment that would emit significant quantities of oxides of nitrogen ("NOx"), one of the principal ozone precursors. Projects of comparable size around the country have exceeded *de minimis* thresholds and required a full conformity analysis under the Clean Air Act. *See e.g.*, U.S. EPA, *General Conformity Guidance: Questions and Answers* (1994) (http://epa.gov/ttn/oarpg/conform/gcgqa_71394.pdf) at 6 (conformity applies to emissions from Section 404 permitted construction). An SDEIS and subsequent documents must provide a full emissions inventory from both construction and operational equipment, along with an analysis of whether a full conformity determination is necessary. The analysis should also include an emissions dispersion analysis for particulate matter to assure that the massive earthworks in the dry environments of the proposed reservoir sites would not violate health-based standards.

In addition, an SDEIS needs to better analyze the effects of the project on the emissions of ozone precursors from the operation of the project. Table 4-15 of the DEIS identifies the massive pumping and power demands that would be associated with this project. The increased electricity demand would likely need to be met primarily with coal-based generation, which would entail significant emissions increases of NOx. These emissions need to be quantified, analyzed and compared to relevant conformity thresholds.

DEIS Section: 4.28.2.1 Water-Based Actions, page 4-104
Statement: *"Although climatic change is considered reasonably foreseeable, there is no accepted science for transforming the general concept of variations in global temperature into incremental changes in streamflow at particular locations. Hydrologic*

changes attributable to global climate change are a possibility; however, potential impacts have not been quantitatively estimated in the EIS because of the uncertainties associated with predicting change and the effects."

And;

DEIS Executive Summary, page ES-14
Statement: *"Climate change may affect precipitation, Poudre River streamflows, and the amount of water available for diversion by NISP, which could alter how the action alternatives operate and, in combination with the action alternatives, could further alter flows in the Poudre River."*

Comment: Even though the Corps acknowledges that climate change and impacts on streamflows are reasonably foreseeable,[15] the DEIS unlawfully brushes aside the potential effects of climate change on the project and the cumulative effects of the project and climate change on natural resources, including stream morphology, riparian vegetation, aquatic and terrestrial vegetation and water quality.

Several recent articles in peer-reviewed scientific journals, as well as national and international scientific bodies, also indicate a growing convergence of predictions regarding climate change in the western US. *E.g.*, Intergovernmental Panel on Climate Change, *Technical Paper on Climate Change and Water* at 137-144 (Apr. 2008); National Research Council, *Hydrologic Effects of a Changing Forest Landscape* (2008). Models consistently predict an ongoing warming trend leading to earlier snowmelt. Predictions of net hydrologic effects are more equivocal, but nonetheless point to a substantial risk of diminished runoff. The Intergovernmental Panel on Climate Change, the leading international scientific effort to address climate issues and the recipient of the 2008 Nobel Peace Prize has concluded that:

> Warming and changes in the form, timing, and amount of precipitation will very likely lead to earlier melting and significant reductions in snowpack in the western mountains [of North America] by the middle of the 21st century. In projections for mountain snow melt-dominated watersheds, snowmelt runoff advances, winter and early spring flows increase (raising flooding potential), and summer flows decrease substantially. Hence, heavily-utilized water systems of the western U.S. and Canada that rely on capturing snowmelt runoff could be especially vulnerable… [IPCC (2008) at 138]

This acknowledgement is the only reasonable conclusion in light of the scientific consensus on this issue. According to the Intergovernmental Panel on Climate Change ("IPCC"), "[w]arming of the climate system is unequivocal, as is now evident from observations of increases in global air and ocean temperatures, widespread melting of snow and ice, and rising global average sea level." IPCC, Summary for Policy Makers: Climate Change 2007 at 5 (Feb. 2007). Moreover, "[m]ost of the observed increase in global average temperatures since the mid-20th century is *very likely* due to the observed increase in anthropogenic greenhouse gas concentrations." *Id.* at 10. Thus, the world's leading scientific body on the subject has now concluded, with greater than 90 percent certainty, that emissions of greenhouse gases are responsible for climate change. *Id.*

The federal government has also acknowledged the same likely impacts of climate change to the Mountain West:

> Mountain West — Higher winter temperatures are very likely to reduce late winter snow-pack. This is likely to cause peak runoff to be lower, which is likely to reduce the potential for spring floods associated with snowmelt. As the peak flow shifts to earlier in the spring, summer runoff is likely to be reduced, which is likely to require modifications in water management to provide for flood control, power production, fish runs, cities, and irrigation.

U.S. Department of State, U.S. Climate Action Report 2002, *Third National Communication of the United States of America under the United Nations Framework Convention on Climate Change* (2002) (available at http://www.gcrio.org/CAR2002). [16]

7. Procedural Issues

DEIS Section 2.1.1.1 Independent Review of NISP Alternatives Evaluation, page 2-2
Statement: *"The Phase II report used a multi-tiered screening process through which water supply concepts and elements were screened, and those that passed screening were used to develop a set of alternatives."*

Comment: The basic alternatives were developed prior to initiation of the NEPA process, but there is no indication that they were ever evaluated or measured against the issues raised by the public during scoping, other than in the analysis of effects. In fact, it appears that the comments raised during scoping were generally ignored. No alternatives were developed specifically to address issues raised in scoping and there is no tracking system in place that allows the reviewer to track comments through the analysis process.

DEIS Section 2.1.2.1 Purpose and Need Screening Criteria, page 2-5
Statement: *"The Project concepts and elements were screened using three purposes and need criteria: firm yield, timeliness, and regional project, as described below."*

Comment: The alternatives were basically developed prior to public scoping and identification of the 24 main issues raised in that process. Although the alternatives developed may have been evaluated against the issues raised, no alternatives were developed in response to the issues raised. Consequently, public involvement resulting from scoping appears to have been ignored in the early stages of the NEPA process.

[16] The United States EPA also identified these projected impacts to water resources in the West from climate change: www.epa.gov/climatechange/effects/water/northamerica.

DEIS Section 2.1.2.2 Environmental Screening Criteria, page 2-5
Statement: *"Wetland areas were estimated using National Wetland Inventory maps, the Phase II report (MWH 2004), and/or geographic information system (GIS) tools, as discussed in the Alternatives Evaluation Report (HDR 2007a)."*

Comment: Although adequate for concept development, the National Wetlands Inventory (NWI) is not sufficiently accurate for project level planning. Many small wetlands will be overlooked and many of the units identified in the inventory will be wrong. This approach does not allow for identification of project specific impacts or evaluate the impacts that might result from required mitigation. There is no assessment as to whether the mitigation can even be accomplished "in-kind" and "in-place." Under section 404 of the Clean Water Act and NEPA, this is an inappropriate use of "adaptive management." *See* Section II.5 of these Comments.

DEIS Section 2.1.2.2 Environmental Screening Criteria, page 2-6
Statement: *"Therefore, any new proposed reservoir element located on a perennial stream was eliminated from further evaluation."*

Comment: The assumption that perennial streams should be dropped from consideration seems based on false assumptions. The decision appears to be based on the inability of the proponents to collect an adequate level of information during their planning process. This decision may have eliminated viable alternatives.

DEIS Section 2.4.1 Operational Flexibility, page 2-30
Statement: *"The District has the following needs for operational flexibility for the Proposed Project."*

Comment: The City cannot seriously evaluate the effects of the project with so little information provided regarding implementation and operation of the project. The specific impacts of these options cannot be evaluated in the context of the entire project's operation. An SDEIS is necessary to provide the requisite data and take the legally required "hard look" at the alternatives considered and the Proposed Project.

DEIS Table 3-17 Wetlands and Other Waters, Glade Reservoir Study Area, page 3-49
Statement: *"A determination has not been made regarding the jurisdictional status of these wetlands and other waters under Section 404 of the Clean Water Act."*

Comment: A jurisdictional determination must be made and circulated in an SDEIS prior to making a decision or issuing a permit. Presently, it is impossible to know the amount of wetlands mitigation that will be required, where it will be developed, and the

impacts that might develop as a result of wetlands mitigation-related activities. Since this is a project specific proposal, the Corps must base its evaluation on project specific information before a decision can be made. *See* discussion in Sections II.6 and II.7 of these Comments.

DEIS Section 3.14.1 Regulatory Framework, page 3-61
Statement: *"The Fish and Wildlife Coordination Act requires the federal action agency to consult with the U.S. Fish and Wildlife Service (Service) and the CDOW on issues related to conservation of wildlife resources for federal projects resulting in modifications to waters or channels of a body of water (16 U.S.C. §§ 661–667c)."*

Comment: The DEIS makes no mention of the Bald and Golden Eagle Protection Act. *See* 16 U.S.C. 668-668d. The Corps must comply with that Act in addition to others noted, including identifying, analyzing and considering incidental take issues as they relate to eagles.

DEIS Section 4.12.4 Summary of Effects to Wetlands and Other Waters, page 4-50
Statement: *"Table 4-9 summarizes the direct effects to wetlands and other waters that would occur under all of the alternatives."*

Comment: This "summary" of the effects on wetlands and other waters fails to address the effect of building or providing the necessary mitigation to alleviate these impacts. It must be redone in an SDEIS that addresses such questions as: Where will the new mitigation occur and in what quantities? What impacts will result from creation of the mitigation? Will the mitigation offset the impacts to the sites identified in Table 4-9?

DEIS Section 4.15.2.1.1 Upstream of Fort Collins, page 4-61
Statement: *"Therefore, the information on hydrology and habitat availability for fish and invertebrates indicates that the action alternatives would result in a minor beneficial effect to fish and invertebrate communities in this segment of the Poudre River (Table 4-11)."*

Comment: These conclusions differ considerably from those on other rivers in Colorado. For example, reduced winter and spring flows on the Yampa have had a major negative effect on critical downstream spawning habitat for endangered fishes. This evaluation fails to address the effects of reduced flows on the creation or elimination of specific spawning habitats for individual species.

Part V - Recreation, Aesthetics, Socioeconomics & Cumulative Impacts

1. General Comments

The proposed action will have negative impacts to the quality of life of Fort Collins residents. There will be impacts to the general economic health of the community and to aesthetic and recreation values. These quality of life indicators are strongly correlated with the biological condition of the Poudre River, its visual appearance, and its ability to support recreation activities. The millions of dollars invested by the City in reliance on the continued viability of the Poudre River evidence and illustrate the importance of the River in Fort Collins and to Fort Collins residents.

The great importance the City places on the Poudre River is reflected in several key planning documents. Overall guidance is provided by City Plan, the City's comprehensive plan, which states in the community vision: "The Poudre River will be a major part of a coordinated system of open lands that includes the foothills, corridors, streams and other water bodies, parks, natural areas and community separators." (City of Fort Collins City Plan at 10). City Plan further states, "The Poudre River Corridor is highlighted in *City Plan* because of its special significance to the entire Fort Collins community…The special significance of the Poudre River Corridor has been recognized in a series of planning documents adopted by the City Council over many years.." (City of Fort Collins City Plan at 229).

Some of the more recent plans that emphasize the importance of the Poudre River to the City include the Downtown River Corridor Implementation Program, Fort Collins Downtown Plan, the Downtown Strategic Plan, North College Avenue Corridor Plan, Natural Areas Policy Plan, Parks and Recreation Policy Plan, Framework for Environmental Action, and Stormwater Master Plan. Protection and enhancement of the River is a common theme in each of these planning documents. Flow reductions undermine these planning efforts by reducing wildlife, scenic and recreational values, as well as the efforts to revitalize areas in the vicinity of the River.

Finally, it is a policy of the City to coordinate with appropriate agencies, when possible, to provide adequate instream flows to maintain ecological, recreational, and scenic values in the Poudre River Corridor (Policy PRC-2.4 Instream Flows).

There are two types of flaws critical to the DEIS analyses of recreation, aesthetics, and socioeconomics. First, there are significant and unacceptable omissions in the analyses of these issues. For example, the assessment of community impacts fails to include the community of Fort Collins when it concludes there will be no community cohesion or quality of life impacts associated with any of the action alternatives (See Section V.3d that follows). Another example is the omission of the DEIS to identify the potential that impairment of water quality in the Poudre River that may result from the reduction in flows that NISP will cause could result in future "no body contact" and "no swimming" zones in the River. *See* comments regarding DEIS Section 4.5.9 in Section III…2a of these Comments. Such degradation of river conditions could severely impair or preclude

the continued use of the River for recreation. Without recognizing this concern, analyses of the impacts to boating and fishing and other forms of recreation are incomplete.

Second, there are numerous significant errors, inaccuracies and inconsistencies in the analysis and conclusions of the DEIS and supporting technical reports, as described in Parts III through V of these Comments. These errors and inconsistent conclusions about impacts to water quality and the ecology of the Poudre River throughout the DEIS undermine analyses of recreation and economic impacts. For example, the DEIS repeatedly makes contradictory conclusions about impacts to the riparian vegetation and wildlife. See Section IV.3b and Section IV.5c of these Comments. If, for example analyses of riparian vegetation and wildlife habitat are inconclusive throughout the DEIS, then dependant analysis and conclusions about the impact to recreational wildlife viewing is unsupported. Similarly, the limitations of these ecological analyses prevent a meaningful analysis of visual and aesthetic impacts, which depend upon a meaningful understanding of the impacts NISP would have on riparian vegetation and invasive species.

This theme of inconsistency is carried into the socioeconomic and recreational analyses. For example, DEIS Attachment G: Technical Memorandum- NISP Visual Impacts to Recreation Activities states:

> *"Reduced water flows in the river would decrease the area of riparian vegetation communities and surface water. Potential effects to visual quality from active and passive recreation areas in Lee Martinez City Park (Fort Collins) would be negligible. Although smaller in area, riparian plant communities would persist, and continue to screen the park from adjacent industrial and residential land uses. Effects to the long distance visibility of trees within the remaining riparian plant communities would also be negligible…. Although fewer in quantity, the same species of trees would remain at the same size and same locations as presently exist."*

This excerpt, which is based on little if any scientific evidence, makes no clear statement, is not consistent with other sections of the DEIS and does not support the assertion that impacts to wildlife viewing and aesthetics will be negligible (*See* Sections V.2b and V.3e that follow).

To summarize, because of the analytical problems found in the more readily measurable and quantifiable impacts described in Parts III and IV, rigorous identification of issues regarding the impacts NISP would have on Recreation, Socioeconomics and Aesthetics, meaningful analysis of those impacts, and consideration of ways in which those impacts may be addressed, is hindered and, to some extent, not possible. The Corps must evaluate and address the impacts of NISP on these areas of concern and fully address the expected impacts in accordance with the Section 404(b)(1) Guidelines. *See* Section II.1a of these Comments for further discussion in this regard. Additional identification and analysis of these impacts, building upon the additional work needed to address the

concerns noted throughout these Comments, must be completed and incorporated into an SDEIS and Revised Section 404(b)(1) Analysis.

1a. Impact of the Proposed Action on Fort Collins' Economy

The City of Fort Collins has built substantial infrastructure along the Poudre River and based substantial investments upon the location and character of the Poudre River as it flows through Fort Collins. This may result in part from the fact that the Poudre River flows through the original center of the City. These investments and infrastructure improvements range from the design and construction of multi-million dollar wastewater treatment plants, to the acquisition of parks, Natural Areas and trail alignments along the River, to the completion of Downtown land use and infrastructure plans to complement and encourage interaction with the nearby reaches of the River.

Below is a table depicting selected projects, acquisitions and investments of the City of Fort Collins in and around the Poudre River, along with the general timeframe for the expenditures. This table illustrates the extent to which the River has been central to City programs and priorities.

[Remainder of Page Intentionally Left Blank]

Summary of Selected City Investments and Acquisitions Along the Poudre River

Poudre River Projects	Year	Cost
Natural Areas Acquisitions (see page 94 for detail)	1955 – present	$8.4 million
Natural Areas Restoration and Rehabilitation	2003 -- present	$500,000
Park Acquisitions (see page 193 for detail)	1960 - present	$14.6 million (present day values)
Poudre River Trail (see page 193 for detail)	1980 – present	$8.3 million
Drake Water Reclamation Facility Levee	1992	$462,000
Pickle Factory Site Purchase & Improvements	1995	$290,000
Stormwater Land Acquisitions	2001 – present	$360,000
Old Fort Site Historic Survey Project	2002	$35,000
Poudre River Enhancement Project	2003	$120,000
Bicycle/Pedestrian Bridge over Poudre River	2002	$998,007
Timberline R-Path Levee	2000	$50,000
Downtown River Corridor Preliminary Brownfields Pilot Assessment Project	1999	$250,000
Targeted Brownfields Assessment – Poudre River	2004	$80,000
North College Improvements – Phase I	2005	approximately $5 million
Oxbow Levee	2005	$700,000
Northside Aztlan Community Center Construction	2007	$10 million
Timberline L-Path Levee	2007	$1.5 million
Downtown River District Infrastructure Project	2008/ in progress	$200,000 for planning $3 million ($1.5 million in federal funds, and $1.5 million in Downtown Development Authority funds) Estimated costs of full implementation is $17.5 million
Museum/Discovery Science Center	in progress	$363,000 for land (partial) $9.6 million ($6.6 million in dedicated City tax revenues and $3 million in private foundation funds) for development

As noted above, the Downtown River Corridor – the area directly adjacent to both sides of the River between North College Avenue and Lemay Avenue – is the focus of the City's revitalization efforts. As a result, there have been considerable investments made by the private sector and other entities along the River Corridor, in addition to the City's

investments. The attractiveness of the River to housing, office and recreational uses has been a key factor in these investments. A few recent projects include:

- In-Situ, a 30,000 square foot office building along the Poudre River off of Lincoln Avenue. In-Situ located in Fort Collins in part to be near the Poudre River.
- Rooftops on the River, a housing project under construction near the Poudre River off of Willow Street.
- Mason Street North, a mixed use project located near the Poudre River off of Mason Street.
- Old Town Athletic Club, a project that renovated an older building on Linden Street.
- Colorado State University's Environmental Learning Center at Drake Road.
- Colorado State University's Engine and Energy Conversion Laboratory at the Old Power Plant Site along the Poudre River off of North College Avenue.

Many other private projects have been proposed for the Downtown River Corridor. Changes to the morphology, vegetation, and aesthetics due to reduced river flows may have an adverse impact on the attractiveness of the River Corridor for private investment.

In Fall 2007, Dr. John Loomis of Colorado State University conducted a scientific, peer-reviewed survey of Fort Collins households to determine the economic benefit (non-market valuation) of maintaining peak flows in the Poudre River through Fort Collins. *See "Estimating the Economic Benefits of Maintaining Peak Instream Flows in the Poudre River through Fort Collins, Colorado"* (the "Loomis Report") (Loomis, 2007).

As described in the Loomis Report, a mailed survey questioned a random sample of 550 Fort Collins households (with an impressive response rate of 64%) found that slightly more than two-thirds (66%) of the respondents thought a 50% reduction in flows was a very bad change with an additional 15% believing it would be a bad change. Thus, more than 80% of the households surveyed believe a 50% reduction in flows is a bad change. A 50% reduction in flows is within the range of reductions from NISP predicted for Fort Collins.

The Loomis Report notes that the same survey also found that three-fourths (75%) of Fort Collins households surveyed have visited the Poudre River in town at least once, and more than half do so every year, with a median of 6 trips per person. Using a federally accepted Contingent Valuation Method, the median value of $15 per visit per survey respondent was estimated. Given the six trips per person per year with a value of $15 per visit, this translates to an annual recreation value of $90 per year per household. When median and mean willingness to pay results are generalized to the percentage of households in Fort Collins that responded to the survey, the analysis yields an annual benefit of $8.5 million to $12.7 million with a present worth or value of these benefits in perpetuity estimated at $283 to $424 million. These impacts must be considered in the Corps' public interest review required by 33 C.F.R. § 320.4(a). It is consistent with the

contingent valuation studies frequently used to estimate the effects of federal actions in the benefit-cost context.

The Socioeconomic analysis in the DEIS is also profoundly deficient in its lack of assessment of the impacts that NISP will have on the economy of the City. The Cache la Poudre River and its attendant natural environment, recreational amenities and aesthetics are critical to the economic health – present and future – of the City.

Surveys and studies conducted for the City have shown that the River and its amenities are central components to the high quality of life in the City, which, in turn, is essential to the economic development of the City. *See e.g.*, *City of Fort Collins Communication and Public Information Office, Brand Report Summary* (the "Brand Report") (available at http://fcgov.com/business/pdf/brand_summary_cpio.pdf). High quality of life is an integral part of retaining and attracting the high-skill, high-education and creative workers that are essential to the high-technology, biotech, brewing and other jobs that drive the local economy. *Id.*

The River has made the City extremely competitive in attracting highly desirable workers and businesses. *Id.* Indeed, the City regularly wins awards and recognitions nationally for its recreation and quality of life due in large part to the recreational and environmental qualities of the River. The City has recently won awards as the "Best Place to Live" from *Money Magazine*, "One of America's Most Walkable Small Cities" from *MSN.com*, one of the "Best Places to Live" from *Men's Journal*, "One of 18 Perfect Towns" and "One of America's Dream Towns" from *Outside Magazine*, "Bicycle Friendly Community" from the League of American Bicyclists and "Top Retirement Spot" from *Where to Retire Magazine*. See Why Fort Collins? Quality of Life (available at http://www.fcgov.com/business/qol.php.).

City residents identify the natural beauty of the River, the mountains and parks as the greatest asset of the City. *Id.* State tourism and economic development officials, along with industry experts, highlight the City's outdoor recreation opportunities, clean water and hiking/biking trails as essential parts of the City's "brand" and economic development. Brand Report at 2-4. "Fort Collins possesses incomparable brainpower, an excellent education system, a desirable quality of life and vast open space – all important factors when competing for and retaining those companies and jobs that will ensure a diverse and prosperous economy." *Id.* at 10. The outdoors and open space are identified as among a handful of "key economic drivers" for the City. *Id.* at 11, 13. The economic development benefits spin off to all of Northern Colorado, which shares in the City's economic success.

As an example of the importance of the River to the City's economy, City economic development promotional material highlights the River, City Parks, City Natural Areas and bike paths as essential elements of the quality of life that attracts businesses and high-value workers. *See* "The Fort Collins Way of Life" (available at

http://www.fcgov.com/business/pdf/FortCollins_QualityofLife.pdf). It highlights photographs of a fly fisherman with a significant stream flow and healthy vegetation. *Id.*

City economic redevelopment and land use plans also revolve around a healthy River. For example, the City's River District plan is based on the connection of the City and its built environment with "recreation on the river and preserved natural areas." City of Fort Collins, River District Plan at 2 (available at http://fcgov.com/riverdistrict/pdf/river_district.pdf).

All of these efforts will be substantially impaired by the impacts of NISP on the River. As discussed in Parts III through V of these Comments, the reduction of Poudre flows by 25 % to 71 % would lead to potential algal blooms, fish kills, losses of native vegetation, choking of the stream channel, impairment of fishing and boating, potential losses of birds and other species, and the aesthetics of the River Corridor. These impacts are completely at odds with the City's and region's economic future. The Loomis Report confirms that residents already perceive the degradation to quality of life and recreation that a large reduction in flow will cause.

1b. Impact of the Proposed Action on Recreation

As reported in the Loomis Report (2007), survey respondents were asked how their visits to the Poudre River in Fort Collins would change if peak spring and summer flows were reduced by half. About one-third would visit less with the lower flows, 5 percent would stop visiting altogether, and about half would not change their visits (the remainder currently do not visit the River and the lower flows would not change that). Combining all the responses yields an average reduction of 3.2 visits per person, with a median reduction of 2 fewer visits per person with a 50 percent reduction in flow. Given the reported current median visits is 6 trips per person per year, this is a substantial decrease (-33%) in the median number of visits made to the Poudre River if flows were cut in half. Given the economic value of $15 per visit, average annual recreation losses are between $30 and $48 per Fort Collins household and represent a loss of approximately $1.3 million in recreation-related economic activity on an annual basis.

As described in more detail in Section V.2 of these Comments, it is anticipated that reduced flows associated with the proposed action are likely to reduce or eliminate boating and fishing opportunities in the Poudre River during the high recreation spring and summer months. Similarly, modification of the river channel as a result of reduced flows including habitat "terrestrialization" and the loss of native riparian wildlife will reduce opportunities for wildlife viewing that have been enjoyed in Fort Collins for more than half a century. Assuming that the proposed action were to be approved, over a period of time the River Corridor may visually appear more like a "canal" than a river, which would be expected to reduce visitor enjoyment and usage.

Property	Site Acres	Present Day Value	Acq. Year	Management Purpose	Miles of Trail	Recreational Uses
Lee Martinez Park	89.56	$ 11,866,700	1973	Active and passive recreation	0.6	Organized sports (ballfield and turf field sports), tennis, basketball, playground and picnic shelter users, walking, jogging, wildlife viewing, biking, equestrian, dogs, fishing, boating, Poudre River Trail through the park, community gatherings
Legacy Park	8.4	$ 1,050,000	1975	Active and passive recreation	0.2	Walking, jogging, turf for informal play, picnic shelter, wildlife viewing, biking, equestrian, dogs, Hickory Trail through the park, community gatherings
Old Fort Collins Heritage Park	13.0	$ 812,500	1960	Active and passive recreation	0..1	Organized sports (turf field sports) walking, wildlife viewing, biking, playground, dogs, fishing, boating, Poudre River Trail through park, community gatherings
Buckingham Park	5.75	$891,250	1962	Active and passive recreation	0.1	Organized sports (ballfield and turf field sports), basketball, walking, playground and picnic shelter users, wildlife viewing, Poudre River Trail through the park, community gatherings
Poudre River Trail		$ 8,334,750	1980-present	Active and passive trail recreation	10.10	Walking, jogging, biking, wildlife viewing, organized community walks and runs
Totals	**116.71**	**$ 22,955,200**			**11.1**	

Above is a table illustrating the four public parks and the Poudre River Trail that are managed by the City of Fort Collins' Parks Department and affected by the proposed action. The existing water craft course improvements at the Old Power Plant will have a reduced challenge rating and shortened boating season due to the proposed action. The new water craft course that is currently in the development stage will likely be rendered not feasible due to the reduced flows and shortened boating season.

1c. Concluding General Comments

In summary, the Loomis Report indicates a substantial economic and recreation value to Fort Collins households in maintaining current peak spring and summer flows in the Poudre River. It appears the value of these instream flows to Fort Collins residents is of significant magnitude even relative to the market value of the water. Further, the value of water in the Poudre River to the residents of Fort Collins is sufficiently high to suggest that additional water diversions from the Poudre River should occur downstream of Fort Collins even if this involves higher costs to diverters or reduced water yields to diverters.

Finally, these non-market values are part of the Corps' National Economic Development assessment of benefits and costs and must be factored into the Corps' decision on whether or not to permit the proposed action and the mitigating measures that would be included in an approved permit.

Under the Section 404 regulations promulgated by the Corps, the Corps may not issue a permit for NISP if it determines that doing so would be contrary to the public interest based on a "careful weighing" of the probable impacts of the project. 33 C.F.R. § 320.4(a). As has been discussed throughout these comments, the current record is inadequate for the Corps to undertake this analysis, because it fails to account for the economic and noneconomic negative impacts of NISP, while possibly exaggerating the benefits.

The more careful consideration of the public interest required by the Corps' own regulations would show that this project as currently configured is not in the public interest. Adding to the public interest balance the hundreds of millions of dollars of costs the project as configured could cause due to new drinking water treatment infrastructure and operating costs/impacts (*see* Section III.1 of these Comments), needed wastewater treatment infrastructure and operating costs (*see* Section III.2), the loss of stormwater conveyance capacity (*see* Section IV.2), lost recreation from fishing, boating and other uses (*see* Section V.2), the costs associated with impacts such as lost existence value, lost economic development, ecological damage and degraded habitat values would tip the balance towards finding that this project is not in the public interest under Section 320.4(a). Adding these hundreds of millions of dollars of costs to the rate base for NISP participants and realistically considering the effects of climate on reduced yield may lead even consumers of water from NISP to conclude that the project is not in their interest either. *See* Section IV.6 of these Comments.

2. Recreation

2a. General Comments

The Cache la Poudre River Corridor in Fort Collins provides extensive riparian, riverine, and wetlands habitat and recreation opportunities. The City owns 19 Natural Areas comprising 1,423 acres, 4 parks, and over 27 miles of trail associated with the River *See* Table in Section V.1b of

these Comments. Surveys have shown that there are over 500,000 visits annually to the Natural Areas alone (City of Fort Collins, 2006). The City has invested over $8 million in its Natural Areas and associated trails along the River (not adjusted for inflation) and over $22 million in parks and trails (current value).

Both the DEIS and the Recreation Resources Technical Report acknowledge impacts from the proposed action on the aesthetics, fishing, boating and economics of the Poudre River through Fort Collins. The proposed action reduces flows in the River and contributes to the "miniaturization" of the River. Reduced flows result in less environmental diversity along the River and consequently a reduction in the recreation resource value to the community. An SDEIS and Revised 404(b)(1) Analysis should be prepared to contain the appropriate and legally required level of analysis, detail and avoidance, minimization or mitigation strategies to address recreational impacts from the proposed action.

The City has invested significant resources in improving the River and creating adjacent infrastructure for the enjoyment of the community. A Cache la Poudre River with sustained flows remains the "heart of the community" and is particularly vital to the continued growth of the downtown area. The proposed action will diminish the health of the River and its recreation value.

2b. Specific Comments on DEIS

Section 2.4.1.4 Sources of Water for Drought Conditions, page 2-32
Statement: *"NISP will have the option of entering into contracts with agricultural water users to lease water that can be subsequently diverted and stored in NISP facilities."*

Comment: The City currently irrigates numerous parks with irrigation ditch water and the impact on these deliveries of water leased by NISP is not addressed. NISP leases and diversion of water from irrigation ditches that supply water to the City's park system may affect the City's ability to convey water to the park system. For example, it may affect the amount and timing of water that is available for use at City parks. Additional analyses related to these potential leases are needed to determine what impacts to the City will result. These concerns are in addition to the potential impacts identified above in Part III of these Comments regarding DEIS Section 2.4.1.4.

Table 4-1. Effects Common to All Action Alternatives, page 4-4
Statement: Recreation Effect: *"Poudre River streamflows downstream from the Poudre Valley Canal diversion would be reduced. This would potentially affect boating recreation on the Poudre River from Shields Street to Prospect Street in Fort Collins."*

Comment: The statement should acknowledge the potential effect to river aesthetics, planned City improvements, other recreational experiences, and the economic value of the River to the

community in addition to boating. The impact should be quantified and more precisely defined in an SDEIS.

Section 4.2.1.7.1 Socioeconomics, Poudre River Recreation, page 4-4-11
Statement: *"Reductions in flow may also adversely impact recreation activities on the Poudre River trail, resulting from a reduction in the aesthetic quality of the recreation experience."*

Comment: The City agrees that reduced flows in the Poudre River through Fort Collins will adversely impact recreation along the River. In fact, the City contracted a scientific, peer-reviewed study with Dr. John Loomis of Colorado State University (the Loomis Report, as described above) to determine the economic benefit (non-market valuation) of maintaining peak flows in the Cache la Poudre River through Fort Collins.

It is important to note that this survey asked citizens about a 50% reduction in peak spring and summer flows. It is noteworthy that some of the modeling detailed in the DEIS suggest up to a 71% reduction in flows during the same periods. One would logically conclude that had the survey asked about a 71% reduction, there would be a corresponding increase in adverse responses.

The aesthetic value of the River includes the recreation experience people have being adjacent to or on the River. Reduced flows will result in a diminished experience for fishermen if the River has fewer and less desirable fish, experiences fish kills and has a less diverse vegetative habitat that could compromise the aquatic community. Park and trail users will also be impacted by the potential for the composition of the River to present fewer and reduced eddies and ripples during reduced flows with resulting loss of enjoyment. Bird watching, for example, could be impacted if the cottonwood tree population or other bird habitat is diminished due to reduced flows or reduced flooding. Boating users could experience frustration with low flows in the River, a reduced channel width and the floatability of the River. The result would be fewer fishermen, boaters and in general fewer people coming to the River for recreational purposes.

Section 4.2.1.7, Socioeconomics, Page 4-11
Statement: *"Since aesthetic impacts are anticipated to be negligible, economic impacts are uncertain, but are expected to be similarly negligible."*

Comment: This conclusion is not supported by data or factual findings in the DEIS or supporting documents. It runs contrary to the findings of the Loomis Report. The Loomis Report (see attachment to these comments) indicates a high value to the community for maintaining current river flows. The DEIS finding that "aesthetic impacts are anticipated to be negligible" ignores the further reduction in human and natural value of the River likely to result directly and indirectly from decreased flows. Reduced flows could jeopardize the survival of native fish, and changes to river flow and water quality could result in fish kills and a less diverse plant environment and resulting loss in wildlife species diversity. The human experience of the River will be diminished with this overall reduction in aesthetic richness.

Comparison of Alternatives (Table 4-6) and Distinguishing Effects of the Alternatives, Page 4-16
Statement: *"If Glade is managed for public recreation, it would provide a new sport fishery."*

Comment: This section of the chart should reference the potential for negative impacts to fishing through Fort Collins in order to provide a comprehensive overview of the impacts to fishing.

Section 4.17.3.1 Poudre River Recreation, Page 4-72
Statement: *"A water craft course is currently being planned for this location and has a preliminary minimum design streamflow of 150 cfs."*

And;

Section 4.22.2 Impacts Common to Action Alternatives, Page 4-102
Statement: *"Currently, the feature of the course will be designed to function at flows as low as 150 cubic feet per second (cfs)."*

Comment: Recent research by the consultant hired to design the water craft course, indicates that a minimum flow of 250 cfs is a realistic value for a viable course, with the desired flows to range up to over 500 cfs. McLaughlin Whitewater Design group, 2008. Additional analysis is needed in an SDEIS to determine the magnitude of the impact reduced flows from NISP would have on the water craft course. Flow reductions of the magnitude anticipated from NISP likely render the proposed water craft course impracticable or of very little usefulness, depending upon the timing and extent of reduction of river flows in this location. If the number of days that flows of sufficient volume are available is significantly reduced, the course would get little use, would have little economic impact, and would not be worth building. *Id.* This must be addressed in an SDEIS and Revised 404(b)(1) Analysis.

Section 4.17.3.1 Poudre River Recreation, pages 4-72-73
Statement: *"Fishing along this reach of the Poudre and in several of its associated ponds is growing in popularity and may be affected by streamflow changes that affect fish population and pond water levels."*

Comment: Additional analysis is needed to determine the real magnitude of the impact on fishing through Fort Collins on the River and adjacent ponds. As indicated in the City's comments on the aquatic resources sections of the EIS, the impacts to aquatic resources should be characterized as major given the significant changes to the flow regime and concomitant changes in channel morphology, habitat composition, etc. The DEIS does not sufficiently describe or quantify impacts to recreational fishing

Section 4.17.3.1 Poudre River Recreation, page 4-73
Statement: *"Use of the Poudre River trail and nature observation are not expected to have more than minor impacts due to any diminished aesthetic qualities."*

Comment: This conclusion is not supported by any rigorous analysis and is contrary to the findings from the Loomis Report. The Report indicates that the community has a high value for maintaining current river flows. The diminished plant, aquatic and wildlife environment of the River resulting from the impacts to the River itself, will result in fewer people coming to enjoy the River. Activities such as bird watching, photography of nature, school outings to learn about nature, and other recreational opportunities have the potential to be reduced, resulting in less human experience and interaction with the river environment. The river environment of the Poudre River is largely "aesthetic" for many Fort Collins residents and reduced flows will impact this community value, particularly during the periods of lowest river flows.

Section 4.17.6 Mitigation, page 4-75
Statement: *"The District would seek an agreement with the Lake Canal Company to move diversions from the Lake Canal intake on the Poudre River near College Avenue to the Timnath Reservoir Inlet Canal about 3 miles downstream. On average, moving the diversions from the Lake Canal downstream will add about 50 cfs to the Poudre River for 6 weeks from late May to early July."*

Comment: It is unlikely that a successful effort by the District to move the Lake Canal intake would be helpful to the viability of the water craft course. The DEIS includes no analysis of the impacts from the significant flow reductions to result from NISP, no discussion of avoidance or minimization of reduced flows, no definite commitment, no enforceable mitigation measure and thus no effective, acceptable mitigation of this impact. The aspiration expressed in this statement is not effective. Moreover, analysis of the effect of retaining 50 cfs for six weeks through a portion of the City is needed to determine the extent to which detrimental impacts from flow reductions would be avoided. An increase in flows of 50 cfs to offset the reductions projected to result from NISP is not likely to be sufficient to result in a viable water craft course, and clearly would not allow for strong regional draw anticipated from current peak flow levels. McLauphlin Whitewater Design group, 2008.

Table 4-20, Summary of Estimated Effects for the Alternatives, Chart, No. 15, Recreation Resources, Boating (kayaking and canoeing), page 4-132
Statement: *"Tubing on the Poudre River would be unaffected by reduced flows."*

Comment: This conclusion is not supported by any analysis in this section. Tubing activities have become extremely popular in the last several years through Fort Collins with many hundreds, and probably thousands, of users annually (there is no data set available). The reduced flows associated with NISP will almost certainly reduce the recreation season for in-town tubers and this effect (and similar effects to canoers, rafters, and kayakers) should be quantified in an SDEIS .

Chapter 4, Table 4-20, Summary of Estimated Effects for the Alternatives, Chart, No. 15, Recreational value, page 4-145
Statement: *"Offsetting impacts. Approximately $0.30 to $1 million in annual loss from Poudre River activities. Approximately $17 million in benefit from recreation at Glade Reservoir."*

Comment: The analysis of impacts of NISP on recreational values on the Poudre River is not based upon adequate data. As noted below, the Recreation Resources Technical Report (p. 19) notes that no recreation/user data was developed as the basis for evaluation of recreation impacts.

Further, the cited passage implies that potential Glade recreation values will offset lost recreation values on the Poudre River in Fort Collins. The City does not agree with this implication. First, the Loomis Report (attached to these comments) indicates a high value to the community for maintaining current river flows. Further, this implication is not supportable because the offset in recreation is not in-kind. River kayaking and fly-fishing would be replaced by flatwater boating and fishing. Additionally, recreation opportunities several miles outside of Fort Collins at Glade would not offset recreation along the Poudre River in the central downtown of Fort Collins, or inside Fort Collins generally.

Even if recreational opportunities at Glade Reservoir could adequately substitute for recreational opportunities along the Poudre River in the center of Fort Collins, the supporting basis for the estimated benefits from the Glade recreation is flawed. As described in the Socio-economic Resources Technical Report, the $17 million estimate is based on the assumption that Glade would experience an equivalent amount of recreation as Horsetooth Reservoir, but that there would be no reduction in recreation at Horsetooth. This key assumption is not supported by any data or analysis. In addition, the development of recreational facilities at Glade would be dependent upon the investment of funds, likely public funds, at a time of increasing scarcity of public and private resources. Without any commitment or demonstration that such investment will be forthcoming, the Corps cannot reasonably expect these $17 million in benefits.

Table 4-20, Summary of Estimated Effects for the Alternatives Chart, No. 15, Recreation Resources (Page 4-15)
Statement: *"Additional cumulative impacts to recreational value may occur."*

Comment: These additional cumulative impacts are not adequately addressed and may result in the reduction or elimination of existing recreational uses. Additional information is needed for the City to respond.

2c. Comments on Recreation Resources Technical Report (RRTR)

RRTR Section: 3.3., Assumptions, page 19
Statement: *"This report is based on existing information and no formal recreation/user surveys were conducted. Impacts were quantified to the extent possible based on available information; however, in most instances impacts to recreation were qualitative because of the limited amount of recreation user preference data necessary to derive a relationship between surface water elevation and visitor use at reservoirs, and streamflows and visitor use on rivers."*

Comment: The analysis of potential impacts to recreation is hindered by the lack of data and therefore lack of basis for the conclusions reached. The conclusion that impacts to recreation

from NISP would be minor is derived from dubious assumptions only, and is merely speculative. This must be addressed in an SDEIS and Revised 404(b)(1) Analysis.

RRTR Section: 5.1.5., At the LINCGAGE, page 46
Statement: *"Although species diversity and abundance of riparian-dependent wildlife species could be reduced in localized areas, no major changes of species composition or distribution are likely (ERO 2007c). Therefore, no impacts to wildlife-related recreation are expected."*

Comment: The finding of no major impact to riparian dependent wildlife is incorrect and unsupported by the DEIS (see previous comments on the Wildlife Technical Report (WRT)). Therefore, any finding about recreation that is based on the WRT, or other related portions of the DEIS, is similarly flawed. This must be addressed in an SDEIS and Revised 404(b)(1) Analysis.

RRTR Section: 5.1.5., At the LINCGAGE, page 46
Statement: *"Because the highest use of these public recreation areas and the trail occurs during summer, these visual effects to park visitors and trail users would be partially screened by the native deciduous vegetation being in full leaf (Holdeman 2007)."*

Comment: The cited statement is not supported by data or analysis and is speculative. It is also inconsistent with the likely impacts to vegetation, discussed in Section IV.3 of these Comments, that are likely to result from NISP. A partial screening by native vegetation would not likely avoid or substantially reduce the visual impacts, and would have little to no effect during a large part of the year. Indeed, the Loomis Report confirms that residents - - well acquainted with the River - - believe that there would be impacts associated with large reductions in flows. Additional information is required for analysis and meaningful consideration of aesthetic impacts. A visual representation of historic and anticipated flows in the River should be provided to show the aesthetic impact caused by reduced flows. The impacts of reduced flows upon vegetation along the River, and the cumulative impacts on aesthetics should be analyzed and considered. The condition of the River in dry years should be given special attention due to anticipated climate changes.

RRTR Section: 6.1, Mitigation Common to All Action Alternatives, page 75
Statement: *"Relocate the Lake Canal to a more downstream location to mitigate for loss of flow at the proposed Water Craft Course location, but also for the in-town (Shields Street to Prospect Road) canoeing reach. Coordinate with local boating community to relocate this point of diversion to the Timnath Reservoir inlet site to avoid impacts to boating and boating potential."*

Comment: It is unlikely the effort by the District to move the Lake Canal intake would be helpful to the viability of the water craft course. This amount would not likely be sufficient to result in a viable water craft course, and clearly would not allow for strong regional draw anticipated from current peak flow levels. McLaughlin Whitewater Design group, 2008. Analysis of the effect of retaining 50 cfs for six weeks through a portion of the City is needed to determine the extent to which detrimental impacts from flow reductions would be avoided,

reduced or mitigated. Importantly, there is no guarantee that this relocation and coordination can and will occur and provide effective mitigation.

RRTR Section: 6.1, Mitigation Common to All Action Alternatives, page 75
Statement: *"See Vegetation and Stream Morphology Reports for mitigation of any aesthetic impacts along the river corridor."*

Comment: Additional information is necessary for analysis and meaningful evaluation of aesthetic impacts, and related avoidance, reduction or mitigation. A visual representation of historic and anticipated flows in the River should be provided to show the aesthetic impact caused by reduced flows. The impacts of reduced flows upon vegetation along the River, and the cumulative impacts on aesthetics should be analyzed and considered. The condition of the River in dry years should be given special attention due to anticipated climate changes. *See* Section IV.6 of these Comments.

3. Socioeconomics & Aesthetics

3a. General Comments

1. The DEIS fails to provide a detailed, data-driven assessment of the impacts to visual resources and aesthetics along the Poudre River Corridor.
2. The DEIS focuses solely on socioeconomic impacts associated with recreation and confines its review to communities participating in the project. An SDEIS should comprehensively evaluate the socioeconomic impacts (by examining more than recreation, such as economic development) to Fort Collins and other communities impacted by the proposed action. *See* Section V.1 of these Comments.
3. An SDEIS should evaluate cumulative impacts associated with significant Reasonably Foreseeable Actions within Fort Collins that are not included in the DEIS (*See* Section V.3, below).

3b. Specific Comments on DEIS – Aesthetics and Visual Resources

DEIS Section: 3.19 Aesthetics and Visual Resources, page 3-108
Statement: *"This section addresses the existing visual qualities of both the potential reservoir sites and the potential relocation of U.S. 287. These existing qualities may be affected by the construction of any of the reservoirs or the relocation of U.S. 287."*

Comment: As detailed below, the limitation of the visual resources assessment to reservoir areas and the U.S. Highway 287 relocation is inappropriate. Significant vegetation, recreation, wildlife, sedimentation and other impacts may occur as a result of the proposed alternative, and these may in turn impact the visual qualities of the Fort Collins reach of the River. The assessment needs to include all of the study areas identified in the Visual Resources Comprehensive Technical Report (VRCTR), including the Cache la Poudre River.

DEIS Section: 4.19 Aesthetics and Visual Resources, page 4-11
Statement: *"Issues of concern identified during scoping were the potential effect to existing visual quality near the reservoir sites, the visual impact of relocating U.S. 287, and the impact to scenic resources from hydrologic changes."*

Comment: Both this section and the Scoping Report identify the issue of impacts to scenic resources from hydrologic changes. Section 4.3.18 (page 16) of the Scoping Report contains the statement, "*Impacts on the aesthetic value of the Cache la Poudre River from reduced flow were of interest.*" Despite these statements, the DEIS does not contain any assessment of impacts to scenic resources, including the Poudre River, from hydrologic changes. The limitation of commentary to reservoir sites and U.S. Highway 287 clearly does not meet the intent of the issues identified in Scoping nor the Visual Resources description. An SDEIS should provide a full assessment of the impacts of NISP on the visual resources of the River.

DEIS Section: 4.19 Aesthetics and Visual Resources, page 4-11
Statement: *"Since aesthetic impacts are anticipated to be negligible, economic impacts are uncertain, but are expected to be similarly negligible."*

Comment: No data or analysis is presented to support this conclusion. It represents solely the author's opinion and value system relative to "aesthetics". No effort was made to solicit the specific views of the general public or NEPA process stakeholders. Aesthetics was one of the issues identified in the public scoping process, and this section of the DEIS fails to adequately address potential changes to aesthetics to City Natural Area, and parks properties and trails adjacent to the Poudre River in light of reduced flows, modifications to riparian vegetation and wildlife, and other factors outlined in the DEIS.

DEIS Section: 4.19.12 Mitigation
General Comment: Mitigation of visual resource impacts to the Poudre River must be addressed (the DEIS is currently silent) in an SDEIS in the context of an adequate analysis of impacts (which analysis has also been omitted from the DEIS).

3c. Comments on Visual Resources Comprehensive Technical Report (VRCTR)

VRCTR Section 2: Study Area, page 17
Statement: *"The study area for the Visual Resources Comprehensive Technical Report includes portions of Larimer and Weld counties that are potentially impacted by project activities…The study area also includes…the Cache la Poudre River Corridor from the Monroe Canal diversion to the confluence with the South Platte River…"*

Comment: This section lists areas included in the Study Area. However, only the potential reservoir areas are described in subsections 2.1 – 2.3. It appears that the Cache la Poudre River and other areas in the study area were excluded from the subsections. In fact, the entire study

area except for the reservoir sites has been excluded from the report. The report needs to include a description of the visual resources in these other areas (as a subsection); the Visual Impacts section (page 34) needs to include an assessment of impacts due to reduced river flows, potential loss of riparian vegetation, algal blooms and other impacts discussed in Part IV of these Comments; and the Potential Mitigation Measures section (page 47) needs to provide mitigation for any impacts to the reduced visual qualities of the River due to lower flows.

In an SDEIS, the Visual Assessment Report (VAR) should provide photo simulations of the River along the affected Corridor at different flow levels. The analysis needs to provide more assessment on the visual impacts of reduced tree densities and fewer tree species as briefly mentioned as an impact in the Recreation Resources Technical Report (RRTR), section 5.1.5, page 47.

The City requested reference information to support the findings in the Visual Resources Comprehensive Technical Report regarding loss of vegetation and impacts to the visual qualities of the River Corridor. The Corps provided in response the Technical Memorandum: NISP Visual Impacts to Recreation Activities, Dated June 18, 2007, to Stacey Antilla from Mark Holdeman, Regarding Text for Recreation Report. This additional document provides no additional substantive information. This lack of underlying data and analysis reinforces the City's concern regarding the need to gather and analyze data regarding the potential visual impacts.

3d. Specific Comments on DEIS - Socioeconomics

DEIS Section: 4.22.2 page 4-91;

And;

NISP Socioeconomic Resources Technical Report Section: 5.1.2 Community Impacts, page 64 & Table 63, page 114
Statement: *"All of the components of NISP action alternatives are located outside of community boundaries. No community cohesion, quality of life, or access impacts are associated with any of the action alternatives."*

Comment: This statement is inaccurate. Although the construction of NISP facilities occurs outside of incorporated municipalities, reduced river flows impact a number of downstream urban communities (Laporte, Fort Collins, Timnath, Windsor, and Greeley). This report does not assess the impacts on community cohesion, quality of life, or access impacts in these communities so the statement cannot be verified. In fact, many City of Fort Collins' community improvement and development plans are predicated on a robust and healthy Poudre River ecosystem, with connections and access being made between the Downtown and the Downtown River Corridor and the North College Corridor. The impact of reduced flows on these connections is not assessed in the DEIS, and should be part of the analysis.

Because the River is an essential community asset that brings together residents and visitors of all types - gender, race, income, neighborhood and other - it encourages and enhances community cohesion in Fort Collins. Its central role as a biking, running and walking corridor through the City means that it plays an important part in getting residents out of cars and interacting with each other. As discussed elsewhere in these comments, it is an essential part of the quality of life that makes Fort Collins a highly desired location and a critical part of the economic development and redevelopment of the City. The City's comprehensive, community improvement and development plans rely on the River as a critical link between neighborhoods, Downtown, the Downtown River Corridor, the North College Corridor, Natural Areas and Parks.

Community cohesion, quality of life and economic development are all threatened by any action that would diminish the flows of the River, impair water quality, threaten treasured trees and other vegetation, kill or displace fish and impair recreation. Failure to address these important issues through an unsupported blanket dismissal is inconsistent with both the Section 404 Guidelines and the public interest requirements of the Corps' Section 404 implementation regulations. See 33 C.F.R. § 320.4(a); 40 C.F.R. Part 230.

DEIS Section 3.22.2 Socioeconomic Issues, page 3-121
Statement: *"Socioeconomic issues identified in scoping were: Effects to regional population growth"*

Comment: This section does not contain any information regarding effects on population growth in the region, including in and around Fort Collins, despite this being an issue identified in the scoping. The NISP Socioeconomic Resources Technical Report (SRTR) briefly discusses population impacts on participating communities, but does not contain any analysis of the regional population impacts of NISP. The effects of NISP on water rates and the relative desirability of participating communities and neighboring communities could influence migration patterns between communities. In fact, the DEIS on page 4-13 states, "Availability of sufficient water supplies in the municipal areas served by many NISP participants may, however, *help steer growth into those areas* and away from unincorporated portions of the region." [italics added]. An SDEIS needs to assess the effects on <u>regional</u> population growth, not a narrow assessment of population growth effects in the participating communities.

DEIS Table 4-14, Summary of Socioeconomic Impacts for All Alternatives, page 4-94
Statement: *"Action alternatives – Community Impacts – No impact*
Alternative 2 Proposed Action – Recreational value – Offsetting impacts"

Comment: The community impacts on non-NISP communities such as Fort Collins have not been assessed. As described by the City throughout these Comments, the community impacts to Fort Collins may be substantial. In addition, the recreational values proposed for the Glade Reservoir and the existing and future ones for the Cache la Poudre River are much different. For example, Poudre River recreation includes a proposed Downtown water craft course, which allows for popular whitewater boating confined to one or two drop structures in an urban environment. Alternative 2, on the other hand, is likely to provide hypothetical flatwater boating several miles outside of Fort Collins on Glade Reservoir and primarily for motorized craft. As

discussed above, there is no guarantee that any such flatwater boating would be developed and no demonstration that it would satisfy any significant demand that is not otherwise met at Horsetooth Reservoir or other facilities. For each of these reasons, the recreation impacts do not offset.

DEIS Section: 3.2 Types of Impacts Assessed, page 20
Statement: *"With respect to potential economic impacts, the following issues will be considered…"*

Comment: In addition to the list provided, this section needs to examine the issue of whether the project would impact other values in all of the communities affected by the reduced river flows. An SDEIS needs to consider all economic and social impacts, such as the possibility of reduced property values on private and public land, the impacts on tax revenue from reduced visitation, the economic loss from unrealized development projects, and the impacts to the intrinsic value of the River to the non-participating communities.

3e. Comments on Socioeconomic Resources Technical Report (SRTR)

SRTR Section: 5.1.6 Recreational Values, page 74
Statement: *"Lower flows could potentially impact the aesthetics, which could slightly impact the intrinsic value of the projects and development. Any impacts to the recreational value of activities associated with the Downtown River Corridor Implementation Program or UniverCity Connections, with the exception of the Water Craft Course, are expected to be minor…It can be assumed that the recreational value of activities in this stretch of the river would be diminished if the aesthetics of the area were degraded; however, it has been found that there would only be negligible impacts to the aesthetics. Changes to aesthetics are expected to be unnoticeable by most users, so the impact to the recreational experience of low flows is likely something much less than impacts experienced by river-based activities, such as kayaking and canoeing."*

Comment: As mentioned under comments in the Aesthetics and Visual Resources Section above, no evaluation of the aesthetics or visual resources of the Downtown River Corridor was included as part of the DEIS. Therefore, these statements are conjecture and are not based on any objective or scientific assessment. The conjecture is also at odds with the real data reflected in the Loomis Report that indicates that City residents would view reductions in flow in the range contemplated by NISP to be very significant. This section needs to describe specifically how the aesthetics could change, such as the reduction of diversity and density of vegetative cover, reduction of wildlife, exposed bed and banks, potential algal blooms, exposure of rip-rap and man-made structures and other factors due to the reduction of river flows. Photo simulations and surveys should be conducted to evaluate the public's perception of lower river flows and the effects this could have on the visitor's experience and future development along the River Corridor. A visual representation of historic and anticipated flows in the River should be provided to show the aesthetic impact caused by reduced flows. The impacts of reduced flows upon vegetation along the River, and the cumulative impacts on aesthetics should be analyzed

and considered. The condition of the River in dry years should be given special attention due to anticipated climate changes.

The Loomis Report (2007) is one source of objective information of the public's perceptions of reductions in flows in the River. As the report states, "Respondents were asked how their visitation to the Poudre River would change if peak spring and summer flows were reduced in half…about one-third would visit less with the lower flows, 5% would stop visiting altogether…Households were asked whether they viewed reducing the peak spring and summer flows in half as a Very Good Change, Somewhat Good Change, Neither Good nor Bad, Somewhat Bad Change, Very Bad Change, No Opinion, or Not Enough Information…slightly more than two-thirds of respondents thought such a reduction in flows was a very bad change, with an additional 15% stating it was a somewhat a bad change." An SDEIS should disclose, analyze and respond to this information.

3f. Comments on Reasonably Foreseeable Actions and Cumulative Effects Technical Report (RFACETR)

RFACETR Section: 4.28, page 25
Statement: *"**Discovery Science Museum.** Conceptual plans are in place for the construction of a new Discovery Science Museum. Two locations are being considered, one along the Poudre River near Lee Martinez Park and the other north of town and not associated with the river. No formal plans are in place for this project; therefore, this action is not considered reasonably foreseeable."*

*"**Mason Street Corridor Improvements.** The City of Fort Collins plans to improve public transportation by constructing a train system along the Mason Street corridor. This new construction venture would bring more people more easily to the downtown area thereby reducing traffic. This project is still in the planning phase; therefore, this action is not considered reasonably foreseeable."*

Comment: These two projects, identified as "Actions Not Considered Reasonably Foreseeable", should be identified as "Reasonably Foreseeable Actions" in an SDEIS. The Discovery Science Center has a dedicated source of funding and is planned for construction near the Poudre River and scheduled for completion in 2011 (see http://www.dcsm.org/media/pr030108.htm for more information). The Mason Corridor (or "MAX") has also received preliminary approval for federal funding and is currently in an Environmental Assessment review (http://www.fta.dot.gov/printer_friendly/news_events_7787.html). These projects appear to be further along than several of the other projects identified as "Reasonably Foreseeable Actions" – some of which are described as "proposed" or being "investigated".

In addition, there are other projects that need to be included in the list of "Reasonably Foreseeable Actions," as identified below.

1. The Poudre River Enhancement Project (PREP), which was completed in October, 2003. The project provided conceptual designs for the construction of in-stream drop structures, native vegetation plantings, backwater habitats, bank stabilization, water's edge "discovery points" and other recreation improvements along the Poudre River between Linden Street and Lincoln Avenue in Fort Collins. See http://www.univercityconnections.org/docs/poudre-river-corridor.pdf ; http://www.fcgov.com/riverdistrict/pdf/dtrd-200702.pdf . For more information, contact Bob Smith, City of Fort Collins Utilities, at 970-224-6021.

2. CSU's Clean Energy Cluster & Engines and Energy Conversion Laboratory in the Old Power Plant building at College and the Poudre River has been incubating energy businesses at its location, such as Envirofit and Solix. New structures have been built to accommodate these companies, and CSU is planning a much larger expansion in the future. See http://www.eecl.colostate.edu/staff/guy.html

3. The Bohemian Foundation's Amphitheater/Music Venue is planned for the location of a river oxbow between Linden Street and Lincoln Avenue in the Downtown River Corridor. See http://fcgov.com/advanceplanning/pdf/downtown-csu-inventory.pdf

4. The Downtown River District Infrastructure Project has been approved by the Fort Collins City Council and funding available for project work to implement portions of the Project has been identified in the amount of $3 million. The projects meets the criteria for "Reasonably Foreseeable Actions" as there is "a reasonable certainty as to the likelihood of the future action occurring". See http://www.fcgov.com/ riverdistrict.

Appendix A: NISP DEIS Comment Contributors (with professional biographies)

1. City of Fort Collins Staff:

Rick Bachand
Rick Bachand is a Senior Environmental Planner in the City of Fort Collins Natural Areas Program and is responsible for overseeing the Natural Area's ecological restoration program. Rick has a Master's Degree in Forestry from the University of Massachusetts and more than 20 years experience in public and protected land management. In addition to his six years with the City of Fort Collins, Rick previously served with the National Park Service, U.S. Forest Service, and the National Wildlife Federation.

Katy Bigner
Katy Bigner is an intern at Fort Collins Utilities with the Regulatory and Government Affairs Division. She received a M.S. from Bard College in Environmental Policy in 2007, and received her B.A. in Liberal Arts from Colorado State University in 1996. Prior to working with Fort Collins Utilities, Katy served as an intern with the City's Natural Resources Department for her Master's internship. Prior to working at the City , Katy spent seven years in the financial sector as a consumer lender for Norlarco Credit Union. Additionally, she served two years in public service with AmeriCorps with Montana Conservation Corps in Missoula, Montana and with the Bay Area Youth Agency Consortium in Berkeley, California.

Judy Billica, P.E., Ph.D.
Judy Billica is the Senior Process Engineer/Watershed Manager at the City of Fort Collins Water Treatment Facility (FCWTF). Judy has worked for the City of Fort Collins since 1998. For the past two years, Judy's work has focused on water quality within the watersheds that supply the FCWTF, including the Upper Cache la Poudre (CLP), Horsetooth Reservoir, and associated components of the C-BT Project. Special studies conducted or managed by Judy have included design of a collaborative water quality monitoring program for the Upper CLP; a characterization study of total organic carbon (TOC) that is present in our source waters and treatment plant; and process design and treatment optimization studies for TOC removal from waters of the Upper CLP. Prior to working for the City, Judy worked for consulting firms in Colorado and California, as well as in academic research positions. During the span of Judy's professional career, she has worked on a wide range of water quality-related projects, including managing, designing and conducting water quality studies of watershed and ground water systems; designing water and wastewater treatment processes; and developing numerical models, conducting experiments, and performing tracer tests to better understand the movement of water and contaminants through natural and engineered systems. Judy received her M.S. and Ph.D.

degrees in Civil Engineering from Colorado State University and her B.S. degree from the University of California at Davis. She is a registered Professional Engineer in Colorado.

Dennis A. Bode, P.E.
Dennis A. Bode is currently the Water Resources Manager for the City of Fort Collins Utilities. His education includes a B.S. and M.S. in Agricultural Engineering (with emphasis in soil and water) from the University of Wyoming and Colorado State University, respectively. He is a registered professional engineer in Colorado and has been employed by the City of Fort Collins for approximately 30 years working in the general areas of water resources engineering, planning and management. His duties and expertise includes developing policies related to raw water dedication requirements, water supply systems and demand management. He has provided criteria and guidance related to hydrologic and water rights allocation modeling. He oversees the management of the City's raw water supplies including the administration of relevant water rights decrees. He also serves on the governing boards of several irrigation companies and related groups.

Carrie Mineart Daggett, Esq.
Carrie Mineart Daggett is a Deputy City Attorney in the Fort Collins City Attorney's Office, where she has worked since July 1995. In addition to advising the City's Utilities, Natural Resources and Real Estate departments, she also is responsible for environmental legal matters and for supervising the legal work for a number of other City departments and functional areas. She previously worked as an attorney at the law firm of Brownstein, Hyatt, Farber & Strickland (as it was then named) in Denver, and as an associate for the law firm of Beveridge & Diamond in Washington, D.C. Her private practice was primarily in the areas of environmental and regulatory law, and land use and general administrative law. Carrie is admitted to practice law in Colorado, the District of Columbia and Illinois. Her past work experience also includes several years as a management analyst for the State of Iowa's budget office and legislative liaison and executive assistant for the Iowa Department of Corrections. Carrie received her law degree in 1989 from Yale Law School in New Haven, Connecticut, and received her undergraduate degree from the University of Iowa in Iowa City, Iowa.

Donnie Dustin, P.E.
Donnie Dustin is currently a Water Resources Engineer for the City of Fort Collins Utilities. His education includes a B.S. in Geology from James Madison University in Virginia and a M.S. in Civil Engineering (with emphasis in Water Resources Planning and Management) from Colorado State University. He is a registered professional engineer in Colorado and has been employed by the City of Fort Collins for approximately 10 years, 8 of which has been with the Water Resources section. His main function at the Utilities is to provide hydrologic, water rights, and system modeling used to assess the Utilities' current and future water and related infrastructure needs. He is also knowledgeable in the general areas of water resources engineering, planning and management and provides his expertise to develop policies, maintain and protect water rights, and provide water supply and use information.

Keith Elmund, Ph.D.
After graduating from Culver Military Academy, Keith Elmund obtained a B.S. degree in microbiology from Colorado State University. He then served as an officer in the U.S. Air Force

with the 1st Special Operations Force at Hurlburt Field, Florida and later at CCK Airbase in Taiwan. After the service, he came back to CSU and finished his Ph.D. in environmental microbiology. He has been with Fort Collins Utilities for over thirty years starting as a chemist at the Pollution Control Lab. Since 1984, he as served as Environmental Services Manager. In this role, he manages both the City's drinking water quality and pollution control labs. Under his direction the City's Industrial Pretreatment program won two "best in class" national EPA awards. He served an active role in water quality monitoring with the Poudre, Thompson, St. Vrain Group, and on the lower Cache la Poudre River with the U.S. Geological Service, CSU and Kodak Colorado Division since the early 1980s. Most recently, he served a key role in developing the Cache la Poudre River monitoring alliance that is part of EPA's award winning "performance track" environmental leadership program. This program joins together the cities of Fort Collins and Greeley, with the Town of Windsor, the Boxelder and South Fort Collins Sanitation Districts and Kodak Colorado Division in an on-going collaborative effort to monitor and protect over 42 miles of the lower Cache la Poudre River.

Craig L. Foreman, P.E.
Craig L. Foreman is currently Manager of Park Planning and Development for the City of Fort Collins. His education includes a B.S. in Civil Engineering from South Dakota State University. He is a registered professional engineer in Colorado and has been employed by the City of Fort Collins for 22 years. His duties include all aspects of developing parks, trails and special recreation facilities. His expertise includes land and water acquisition, master planning, public involvement, development review, preliminary and final designs for numerous projects and project management. He oversees the management of the City's Park Planning and Development Department.

Kevin R. Gertig
Kevin R. Gertig is the Water Resources and Treatment Manager for the City of Fort Collins Utilities. He is a graduate of Colorado State University with a degree in Environmental Health and is also a graduate of the Water and Wastewater Leadership Center at the University of North Carolina. He is certified in both Water and Wastewater Operations. With a span of 33 years of experience, Kevin's water/wastewater career has included applied research, analysis, design, building, operations & maintenance, special studies, applications of state of the art control systems, drinking water quality, and management. His current responsibilities include overseeing Source of Supply, Watershed Monitoring Program, Water Resources, Water Treatment/Production, Environmental Services, Water Reclamation & BioSolids, Environmental Regulations, Halligan-Seaman Reservoir Project, and a number of capital projects. His past work and expertise includes involvement in regional and national AWWA committees; Universities, awwaRF, AMWA, and training operators around the country to promote the advancement of water science. Kevin was also involved in the Partnership for Safe Water program from the inception, and is the past Vice Chair of sections 5 & 8 in the USA. He was named to the National Infrastructure Advisory group in 2001 and continues to be active in the field of water security at a local, state, and national level. He is an author/co-author of more than 30 papers & articles in water treatment; his contributions include numerous water quality projects in the USA and abroad. Kevin serves as a peer reviewer for the AWWA/WEF QualServe program and has reviewed a number of Utilities throughout the nation.

Marty Heffernan
Marty Heffernan is the Executive Director of Culture, Parks, Recreation and Environment for the City of Fort Collins. Marty has worked for the City since 1991, starting as an Assistant City Attorney. He moved into management in 1996 as the Assistant to the Director of Cultural, Library and Recreational Services. Marty has a B.S. degree in Communications from Michigan State University. He received his Juris Doctorate degree from the University of Colorado in 1983.

Diane Jones
Diane Jones is currently serves as the Deputy City Manager with the City of Fort Collins, Colorado. She has been with the City for 18 years. Her responsibilities include leading and overseeing Community Services and the City Clerk's Office. As Deputy City Manager, she has several years' experience in budget and finance operations, policy and project oversight, and working with a wide variety of community boards and organizations. Prior to joining the Fort Collins' organization, Diane served as the Assistant City Manager in Gresham, Oregon overseeing planning, building, engineering, public works and emergency preparedness operations.

Jennifer Shanahan
Jennifer Shanahan is an Environmental Planner for the Natural Areas Program. Jennifer works with a team of resource management staff to develop new management plans, and to monitor and manage the natural resources on Natural Areas properties. Jennifer has worked for the City since 2006. Jennifer has a M.S. in Rangeland Ecology from Colorado State University. Her thesis work focused on riparian restoration and heavy metal contaminated soils. Prior to employment with the City, Jennifer's work experience included vegetation monitoring, research and analysis, and several years of teaching environmental education in the western United States.

Bob Smith, P.E.
Bob Smith is currently the Water Planning and Development Manager for the City of Fort Collins Utilities stormwater management division. His education includes a B.S. Civil Engineering from the University of Wisconsin-Platteville. He is a registered professional engineer in Colorado and Wisconsin. He has been employed by the City of Fort Collins for approximately 31 years working in the area of stormwater management including stormwater master planning and floodplain administration. His duties and expertise includes hydrologic and hydraulic modeling of federally and locally designated floodplains, overseeing the development and administration of the City's floodplain regulations, the generation of the citywide stormwater master plan used to provide direction for new development and the foundation of the City's stormwater capital improvement program and the City's early warning system used for flooding emergency response activities. He is also the president of the governing boards of several irrigation companies.

John Stokes
John Stokes has served as the Director of the Natural Resources Department for the City of Fort Collins since 2003. The Department operates a large and successful Natural Areas program. The department also has programs related to solid waste diversion, air quality, green house gas reductions, and various City-wide economic and environmental sustainability efforts. Prior to

his work with the City, John spent ten years with The Nature Conservancy, an international non-profit conservation group. Before The Nature Conservancy, John worked with the Appalachian Trail Conference, a non-profit entity responsible for managing and maintaining the Appalachian Trail. John has a Masters in Planning from the University of Virginia and a B.A. in English from the University of Texas.

Carol Webb
Carol Webb is the Regulatory and Government Affairs Manager for the City of Fort Collins. Her job responsibilities include overseeing EPA compliance for city operations including the City's water treatment facility, wastewater treatment facilities, and its stormwater discharge permit. Carol has worked for the City since 1997. Prior to overseeing EPA compliance activities, Carol supervised the City's Pollution Control Laboratory, which provides sampling and analytical services for wastewater plant operations and provides analytical support for an extensive surface water monitoring program along the Cache La Poudre River and Fort Collins' urban creeks. Carol graduated from William Penn College in Oskaloosa, Iowa with a degree in Biology and is currently working toward a Master's degree in Environmental Policy at the University of Denver.

Timothy Wilder, AICP
Timothy Wilder is a Senior City Planner for the City of Fort Collins Advance Planning Department. He has been with the Advance Planning Department for 11 years. Timothy oversees numerous long-range planning projects for the City. In 2000, he was the project manager for the Downtown River Corridor Implementation Program, which involved extensive public outreach to identify critical projects in the Cache la Poudre River corridor. Timothy has nearly 20 years experience in planning and has a degree in planning from the University of California, Santa Barbara. He is a member of the American Institute of Certified Planners.

2. Outside Consultants:

Alaa Aly, PhD, P.E.
Dr. Aly specializes in applying state-of-the-art computational, statistical, and operations research techniques to the development, evaluation, and analyses of hydrologic and agricultural systems as well as development of hydrological, fate, and transport models. Dr. Aly has extensive experience with hydrologic and probabilistic modeling, uncertainty analyses, hydrologic and environmental characterization, water resource management, environmental remediation, and water supply evaluation projects. Dr. Aly received his B.S. in Civil Engineering from Cairo University, a M.S. from Utah State University in Irrigation Engineering, a PhD from Utah State University in Irrigation Engineering, and a second M.S. also from Utah State University in Statistics. Dr. Aly is a registered professional engineer in Colorado, Florida, Wyoming and Utah, as well as being a Certified Ground Water Professional.

Brian Bledsoe, Ph.D., P.E.
Brian Bledsoe has 20 years of experience as an engineer and environmental scientist in the private and public sectors. He earned degrees from Georgia Tech, North Carolina State University, and Colorado State University. He is currently an Associate Professor in the

Department of Civil and Environmental Engineering at Colorado State University. His research and teaching interests are focused on the interface between water resources engineering and river ecology with emphasis on multi-scale linkages between land use, hydrologic processes, sedimentation, channel stability, and water quality. Prior to moving to Fort Collins in 1997, he served as Nonpoint Source Program Coordinator for the State of North Carolina. He has authored over fifty publications related to stream and watershed processes, restoration and water quality, and is a licensed professional engineer in Colorado and North Carolina. His full CV can be viewed at http://www.engr.colostate.edu/~bbledsoe/Bledsoe_CV.pdf

Roy D. Hugie, Ph.D.
Roy D. Hugie is the founder and President of Pioneer Environmental Services, Inc. (incorporated in Utah and Wyoming). He received his B.S. from Utah State University in Wildlife Management and Fisheries. He earned his M.S. degree in Wildlife Biology from the University of Maine (Orono) and his PhD from the University of Montana (Missoula) in Forestry (Specializing in Wildlife). He served as big game research leader, legislative spokesperson, and bear project leader for the Maine Department of Inland Fisheries and Wildlife. Prior to founding Pioneer, he was the NEPA specialist and wildlife section leader for a large consulting firm. With Pioneer he has served as project manager for several water related projects on the Colorado, Green, Platt, Snake, Bear, and other river systems in the west. He also served as the NEPA process, wildlife and wetland specialist for several reservoir projects in Wyoming, Utah, Colorado, and the northeast. His duties and experience in Colorado water projects include NEPA processes, permitting and natural resource studies for the Elk Creek Reservoir (Craig, CO), Lake Catamount Resort (near Steamboat Springs, CO), Muddy Creek Reservoir, Pebbles Jumping Mouse Studies along water courses on the east front (the USFWS) and Halligan Reservoir, and various snowmaking ponds and reservoirs for Telluride, Crested Butte, Steamboat Springs, Vail, Aspen Highlands, and other ski resorts. As president of Pioneer, Roy has had the responsibility and need to be technically conversant in the oversight of hundreds of documents and studies representing a broad spectrum of environmental disciplines. He occasionally provides instruction and lectures on the NEPA process at universities, colleges, and to other audiences.

Jennifer Kathol
Jennifer Kathol specializes in economic and social impact analysis, land and recreation use analysis, environmental justice evaluation, economic and demographic research, Native American issues, local government policy development, fiscal impact analysis, and market analysis. Her professional career has included projects with private companies and individuals, federal, state, and local government agencies, and environmental consulting and engineering firms.

Her over 30 years of experience includes economic, socioeconomic, demographic, land use, and recreation impact analysis for small and large scale resource and industrial projects, local public finance, fiscal impact analysis, and policy development, residential and commercial real estate and product market analysis, property valuation, and pro-forma financial feasibility analysis for a wide range of projects.

She has developed computerized social and economic base model and fiscal impact models for analysis of resource, industrial, and real estate projects. The models can be calibrated to reflect local and regional economic conditions, as well as assess impacts for small and large projects affecting regional geographical areas.

Ms. Kathol has completed fiscal, economic, social, land use, wilderness, recreation, transportation analyses on NEPA Environmental Impact Statements (EIS/EIRs) and Environmental Assessments (EA), and international feasibility analyses for proposed oil and gas pipelines, power plants, refineries, exploratory gas wells, timber sales, ski areas, mines, and transmission lines throughout the west and overseas. She has completed related resource sections, cumulative studies, and technical memorandums for projects in Colorado, Utah, Idaho, North Dakota, Oregon, Montana, Nevada, California, Alaska, Arizona, Wyoming, New Mexico, Russia, Mongolia, Indonesia, Myanmar (Burma), and Armenia. She has extensive experience with both public and private sector entities in assessing economic, fiscal, environmental justice, social, demographic, recreation, visual, and land use issues related to project development.

William J. Miller, Ph.D.

Dr. Miller is President and Senior Aquatic Ecologist for Miller Ecological Consultants, Inc. in Fort Collins, Colorado. Dr. Miller has 30 years experience in fisheries, instream flow, and aquatic ecology studies. He has worked extensively throughout the western U.S. and is a recognized expert in the areas of instream flow, water temperature modeling and habitat assessments. Dr. Miller's experience includes research and evaluations for several threatened, endangered, and candidate aquatic species in the Colorado River and Platte River basins. He has extensive experience in designing and conducting studies using the Instream Flow Incremental Methodology (IFIM), instream water temperature modeling and developing and implementing ecological models for aquatic systems. Dr. Miller is a former member of the USFWS Instream Flow Group. He is co-author on the Stream Network Temperature Model, Instream Flow Information Paper 16. Dr. Miller is a Certified Fisheries Scientist (No. 2008). Dr. Miller's dissertation work included the development of a salmonid fry emergence model that accounted for effects of water temperature, dissolved oxygen and sediment composition. Dr. Miller presented the model at the First Federal Interagency Hydrologic Modeling Conference in Las Vegas, Nevada. Dr. Miller's experience includes designing and directing basinwide instream flow evaluations. He has completed instream flow evaluations for US Forest Service, US Fish and Wildlife Service, Bonneville Power Administration, U.S. Army Corps of Engineers, U.S. Department of Justice, and state and municipal governments. Dr. Miller developed a GIS based methodology for determining flow/habitat relationships for aquatic species using 2 dimensional hydraulic modeling and habitat evaluations. Dr. Miller is co-author and Principal Investigator on an ecosystem model for the recovery of endangered species in the San Juan River basin. Dr. Miller has presented his research at international conferences in Japan (2006) and New Zealand (2007).

Lori Potter, Esq.

Lori Potter is a partner in the law firm of Kaplan Kirsch & Rockwell LLP, Denver. She has practiced environmental law for almost 30 years, specializing in NEPA, the Clean Water Act, public land management and land use law. She graduated from Harvard Law School and received her B.A. and M.A. degrees from the University of Illinois. Ms. Potter's practice focuses

on advising local government clients and owners of mountain and ranch properties regarding adjacent land development, conservation easements, access and related issues. She represents clients nationwide in litigation and administrative proceedings to protect their interests through the NEPA process and other statutes.

John Putnam, Esq.
John Putnam is an attorney and partner at the law firm of Kaplan Kirsch & Rockwell, LLP, in Denver. Mr. Putnam's practice emphasizes counseling and litigation for public and private entities on complex issues of environmental law, especially for large public and public/private projects. Mr. Putnam has extensive experience providing clients nationwide with strategic advice on large and controversial development and transportation projects, including airports, highways, real estate development, telecommunications facilities, and other infrastructure. He counsels clients regarding a wide range of environmental, transportation and development issues, including the National Environmental Policy Act, wetlands, air quality, climate change, sustainability, air toxics, noise, tolling and innovative finance, land use, endangered species, floodplains, municipal law, transportation regulations and Native American jurisdiction. Mr. Putnam received his Juris Doctor degree from the University of Chicago and his Bachelor of Arts degree from Williams College.

Douglas A. Rice, Ph.D.

Doug A. Rice has been the Director of the Environmental Quality Laboratories at Colorado State University since 1992. The Industrial Hygiene laboratory oversees indoor air quality, asbestos, and lead programs for campus. The Environmental Quality Laboratory is responsible for analysis of food, water, soil, and air for the campus and the community. The Environmental Quality Laboratory has coordinated water quality testing and fish / benthic population surveys of the Cache la Poudre River since 1970.

Doug received his Bachelor's degree in 1985 and Master's degree in 1987 from Colorado State University. Doug worked for five years as head of microbiology for the Clorox Company in Pleasanton, California before returning to CSU. In 1998, Doug completed his Doctor of Philosophy degree in Microscopy through the McCrone Institute associated with the University of Chicago. He has consulted internationally in the fields of water quality and mycology.

Jim Schall, Ph.D, P.E.
Jim is Vice President of the Colorado and California operations for Ayres Associates. Ayres is a mid-sized engineering firm with about 400 people in 17 offices. Jim did his undergraduate engineering degree at Purdue University and moved to Colorado in 1977 to do his graduate work at Colorado State University. He started working as a consulting engineer in Fort Collins in 1980, and is currently a licensed professional engineer in Colorado, Nevada and California. Jim's education and nearly 30 years consulting experience encompass all aspects of water resource engineering, with specific expertise in river analysis and design. He regularly works on water resource projects with significant environmental and channel restoration issues. Jim has significant environmental permitting experience including several large water resource EIS projects in Colorado. He has authored widely used design manuals on fluvial systems, including the Design Manual for Engineering Analysis of Fluvial Systems (Arizona DWR), Stream Stability at Highway Structures, HEC-20 (FHWA), and Bridge Scour and Stream Stability

Countermeasures, HEC-23 (FHWA). Dr. Schall is a certified instructor for the National Highway Institute and regularly teaches short courses on urban drainage, scour and sediment transport throughout the country.

William J. Spitz, PG

William J. Spitz is a senior geomorphologist with Ayres Associates where he has worked for 23 years. He has considerable experience using geomorphic analyses that integrate hydrology, hydraulics, sediment transport, geology, and geomorphology to develop process-based understandings of fluvial system dynamics for a wide range of projects and a diverse range of clients. He has been extensively involved in geologic and geomorphic investigations of fluvial systems throughout the United States with highly variable morphologies and stability problems. He has worked closely with federal, state, and local agencies on fluvial systems where there are concerns and issues involving not only stream channel stabilization and rehabilitation, but also restoration, enhancement, and management of riparian and aquatic habitat. He is currently working on projects ranging from watershed erosion assessments in Texas and New Mexico to levee stability assessments and streambank stabilization on rivers in California's Central Valley. Mr. Spitz has been involved with several projects on the Cache la Poudre River including the detailed field investigation and mapping of the morphologic characteristics of the river through the city in the early 1990's as part of the Cache la Poudre Master Drainageway Plan. He is currently involved in the analysis and design of a new permanent replacement for the recently failed temporary low-flow diversion dike on the Cache la Poudre River near the CSU Environmental Learning Center. Mr. Spitz received a B.S. degree in Geology from Colorado State University and is a registered professional geologist in Wyoming and Arizona.

Ellen Wohl, Ph.D.

Ellen is a professor of geology in the Department of Geosciences at Colorado State University. Ellen has been on the CSU faculty since 1989. She teaches courses in river environmental history, geomorphology, and fluvial geomorphology. Her research includes hydraulics, sediment transport, channel morphology, biological-physical interactions in rivers, and human effects on rivers. She has conducted field research on every continent but Antarctica, and much of her research has been conducted in the Cache la Poudre River and South Platte drainage basins. Ellen received her B.S. degree in Geology from Arizona State University, and her Ph.D. in Geosciences from the University of Arizona.

RE: City of Fort Collins' Comments to the Supplemental Draft Environmental Impact Statement for the Northern Integrated Supply Project

Dear Mr. Urbanic:

Please find attached to this letter detailed comments and associated reference material from the City of Fort Collins regarding the Supplemental Draft Environmental Impact Statement for the Northern Integrated Supply Project. Please make this submission a part of the administrative record in this matter. We respectfully submit these comments for your consideration and look forward to the response of the United States Army Corp of Engineers.

On September 1, 2015, the Fort Collins City Council adopted the attached Resolution directing that these comments be submitted on behalf of the City.

If you have any questions, please feel free to contact me, or you may also John Stokes, City of Fort Collins Natural Areas Department Director, at (970) 221-6263, jstokes@fcgov.com.

Thank you.

Sincerely,

Darin A. Atteberry
City Manager

RESOLUTION 2015-082
OF THE CITY OF FORT COLLINS
DIRECTING THE CITY MANAGER TO SUBMIT TO THE U.S. ARMY CORPS OF ENGINEERS THE CITY'S COMMENTS ON THE SUPPLEMENTAL DRAFT ENVIRONMENTAL IMPACT STATEMENT FOR THE NORTHERN INTEGRATED SUPPLY PROJECT

WHEREAS, the Northern Colorado Water Conservancy District ("District") is pursuing the Northern Integrated Supply Project ("NISP"), a water storage and supply project that would divert significant amounts of water from the Cache la Poudre River upstream of Fort Collins; and

WHEREAS, to move forward with the necessary federal permitting for NISP, the District is required by the National Environmental Policy Act ("NEPA") to complete an environmental impact review process, conducted in this case by the U.S. Army Corps of Engineers ("Corps") as the permitting agency under the federal Clean Water Act; and

WHEREAS, as part of the review process, on April 30, 2008, the Corps issued a draft Environmental Impact Statement ("DEIS"), and the City timely submitted comments to the DEIS on September 10, 2008, pursuant to Resolution 2008-002; and

WHEREAS, on June 19, 2015, the Corps issued a supplemental draft Environmental Impact Statement ("SDEIS"), and pursuant to a subsequent extension of time, provided for submission of public comment up to September 3, 2015; and

WHEREAS, at the May 12, 2015, City Council work session, City staff presented background on NISP as well as staff's proposed analytical and data-driven objective approach to commenting on the SDEIS, which approach City Council endorsed; and

WHEREAS, pursuant to the direction of City Council, City staff, working with the assistance of outside technical experts, undertook a thorough and detailed technical analysis of the SDEIS primarily as it pertains to the NISP proposed action and its direct impacts in Fort Collins and to the City; and

WHEREAS, at the July 28, 2015, City Council work session, City staff presented preliminary analyses and findings related to staff's review of the SDEIS; and

WHEREAS, the City wishes to express its support for other communities, including participants in NISP, in their quest to acquire reliable water supplies without significantly adversely affecting other communities and the environment; and

WHEREAS, the City has concluded that the SDEIS is deficient under NEPA and the federal Clean Water Act in various respects, including in its analysis of potential impacts to the City, as set forth in the City's comments to the SDEIS; and

WHEREAS, staff has concluded the project will be harmful to Fort Collins based on a thorough review of the impacts described by the SDEIS as well as the impacts that staff expects from the project; and

WHEREAS, in view of the significance of the impacts that NISP would have on the City and the Fort Collins community, it is in the City's best interest to comment on the SDEIS, to continue to participate in these proceedings, and to monitor the responses to the comments of the City and others.

NOW THEREFORE, BE IT RESOLVED BY THE COUNCIL OF THE CITY OF FORT COLLINS as follows:

Section 1. That the City Council cannot support NISP as it is currently described and proposed in the SDEIS, with the understanding that the City Council may reach a different conclusion with respect to a future variant of NISP, such as the proposed Modified Alternative Number 4 as described in the City's comments, if such variant addresses the City's fundamental concerns expressed in the City's comments to the DEIS and comments to the SDEIS.

Section 2. That the City Manager is hereby authorized and directed to submit to the Corps formal comments to the SDEIS that are substantially similar with those attached hereto as Exhibit "A" and incorporated herein by this reference, in accordance with the deadline for such submission.

Passed and adopted at a regular meeting of the Council of the City of Fort Collins this 1st day of September, A.D. 2015.

Mayor

Comments on Supplemental Draft Environmental Impact Statement
for the
Northern Integrated Supply Project

Dated: September 2, 2015

Table of Contents

INTRODUCTION AND EXECUTIVE SUMMARY

The City of Fort Collins ("Fort Collins") respectfully files and submits to the United States Army Corps of Engineers ("Corps") these comments to the Supplemental Draft Supplemental Impact Statement, dated June 2015 and issued on June 19, 2015 ("SDEIS"), and its associated technical reports and related documents, regarding the Northern Integrated Supply Project ("NISP" or "Project"), for which the Northern Colorado Water Conservancy District ("Northern" or "District") is the applicant. Reference materials are identified in the comments and the majority of such reference materials are being provided to the Corps in electronic format. These reference materials shall constitute part of these comments. Fort Collins reserves all rights to provide additional and supplemental comments on the SDEIS and/or NISP, as may be appropriate.

To the extent permitted by the short comment period, Fort Collins has completed a thorough, scientific review of the SDEIS by expert City staff and consultants summarized in Appendix A. Several of Fort Collins' concerns regarding the original NISP draft environmental impact statement ("DEIS") remain. The SDEIS has also created new issues under National Environmental Policy Act, 42 U.S.C. §§4321-4370h ("NEPA"), and the rules and regulations and guidelines thereunder, the Clean Water Act, 33 U.S.C. §§1251-1387 ("CWA"), and the rules and regulations and guidelines thereunder, and other relevant legal requirements, as discussed herein. In short, the SDEIS remains inadequate for the Corps to discharge its obligations under these requirements, including its selection of the least environmental damaging practicable alternative ("LEDPA") for the Project. *See* 40 C.F.R. § 230.10(a) ("[N]o discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem …").

If a Section 404 permit under the CWA is awarded for the Project, substantial compensatory mitigation will be needed, in addition to any avoidance and minimization measures. It is Fort Collins' understanding that mitigation for NISP will be finalized with any Record of Decision ("ROD"), and that avoidance and minimization measures may be finalized before the ROD. As discussed further herein, Fort Collins notes that, at this point, the District's plans in these respects, which are summarized in Appendix F of the SDEIS, are conceptual and offer limited information on specific measures. Appendix F indicates the intent of the District to recognize and react constructively to impairment of interests other than those of the District and the NISP participants, to be cooperative and responsive, and to participate in all reasonable efforts to address impairments to resources or interests caused by NISP. Where the document does not define specific limits or features of these commitments, however, it is of limited use except as a statement of general intent. Clarification of these efforts is required by NEPA and the CWA. As the entity most impacted by the Project, Fort Collins would welcome the opportunity to participate in mitigation-related discussion and efforts.

Fort Collins' comments are organized by general topic area. In general, the comments begin with broader, more conceptual concerns regarding the SDEIS and the Project, and thereafter turn to more specific issues. Certain reference materials are cited in the text of the comments and all are listed at the end of the section and in Appendix B. The following is a brief summary.

SECTION 1: Incorporation of Fort Collins Comments to DEIS. The comments included herein are a supplement and in addition to the previous comments made to the original DEIS for the Project. Several issues raised in the DEIS have not been adequately addressed.

SECTION 2: Validity of the No Action Alternative. The SDEIS includes consideration of a "no action" Alternative 1, which purportedly would not require federal action. However, Alternative 1 is developed around the proposed Cactus Hill Reservoir that, based on the information provided, appears to require an individual Section 404 permit under the CWA. If the proposed Cactus Hill Reservoir requires a Section 404 permit, then under NEPA, the Corps must revise its alternatives analysis in a new SDEIS to develop a new, true "no action" alternative that can serve as the baseline for analyzing the proposed action's environmental impact. In violation of NEPA and the CWA, the SDEIS's current "no action" alternative skews the analysis to reduce identified impacts, thereby altering the selection of the LEDPA. If the proposed Cactus Hill Reservoir would not, in fact, require a Section 404 permit under the CWA, the SDEIS must expressly set forth why no such permit is needed.

SECTION 3: Failure to Conduct Analyses on All Environmental Impacts, Failure to Fully Address Cumulative Impacts, and Uncertainty Regarding Mitigation Measures. The SDEIS defers several key analyses of impacts to a later date, namely, quantitative water quality analyses. The failure to provide these analyses violates NEPA and such analyses must be provided to Fort Collins and other stakeholders for review before any determination on the Project can be made. The SDEIS also does not fully describe how the cumulative impacts from NISP, Fort Collins' Halligan Water Supply Project, and Greeley's project to enlarge Milton Seaman Reservoir will be assigned to each project. Additionally, the SDEIS's proposed measures to mitigate the environmental impacts of each alternative are vague and the effectiveness of the mitigation has not been adequately documented at this point in the process.

SECTION 4: Proposed Modified Alternative 4. Fort Collins has investigated a modified Alternative 4 for NISP that would meet the NISP Participant's purpose and need while simultaneously maintaining relatively more water in the Poudre River through Fort Collins than all other action alternatives presented in the SDEIS. Such additional flows through Fort Collins would address many of the concerns identified in these comments. The modified Alternative 4 is contemplated to operate in such a way as to significantly reduce NISP diversions upstream of Fort Collins as compared to Alternative 2 (the District's preferred action), as well as Alternatives 3 and 4, resulting in relatively more stream flows and relatively fewer impacts to aquatic and riparian resources along a 23 mile reach of river through Fort Collins than the other alternatives considered in the SDEIS. The Corps must consider and fully analyze this modified Alternative 4 in its analysis and consideration of NISP.

SECTION 5: Water Quality Comments. The SDEIS was issued without several quantitative analyses that would have allowed Fort Collins to meaningfully analyze possible effects on its interests related to the quality of water Fort Collins treats for its potable water supply, as well as the quality of water in the Poudre River. To comply with NEPA's "hard look" standard and the

Section 404 Guidelines, additional analyses must be performed and the Corps must address the specific deficiencies discussed in these comments.

SECTION 6: Operational Comments. The SDEIS's description of Alternative 2 (the District's preferred alternative) includes a proposed flow augmentation program, and certain descriptions of other NISP operations, such as deliveries to NISP Participants. However, the proposed flow augmentation program is only proposed with Alternative 2, which unjustifiably skews the analysis towards the selection of Alternative 2 as the LEDPA. Both NEPA and Section 404 require equal treatment of all alternatives. Also, as proposed in the SDEIS, the proposed flow augmentation program appears to be premised on various incorrect assumptions and errors and raises various concerns regarding its operations that could undermine its ability to meet its goals to address the impacts to Fort Collins. The SDEIS also lacks needed analysis and specificity on various aspects of the proposed operations regarding Alternative 2.

SECTION 7: Channel Structure, Storm Water, Floodplain, and Hydraulic Comments. While the SDEIS is an improvement over the DEIS, the stream morphology and sediment transport analysis in the SDEIS contain several flaws such that the analysis cannot be used to meaningfully analyze NISP's impacts on Fort Collins in the areas of drainage, storm water, and floodplain impacts. The SDEIS also contains assertions and conclusions that that lack factual bases and are arbitrary, including assertions regarding flushing flows. Revised analyses and considerations are required in order to correctly and meaningfully evaluate the impacts. The mitigation measures outlined in Appendix F do not properly evaluate or estimate the amount of sediment that will accumulate within the river through Fort Collins due to the reduced flow from the Project. This amount of sediment needs to be properly quantified and assigned a mitigation cost.

SECTION 8: Air Quality and Climate Change Comments. Fort Collins is concerned with the adequacy of the air quality and climate change analysis in the SDEIS, as well as the impacts of the proposed action. In general, the SDEIS does not fully analyze these impacts (which include greenhouse gasses), which are understated throughout the document. The Corps has failed to take a hard look at the impacts under NEPA, and the lack of analysis prevents Fort Collins and other stakeholders from meaningfully analyzing these effects. To comply with NEPA and the Clean Air Act conformity regulations, the Corps must conduct revised and additional analyses. The Corps must conduct such analyses and present them for public review and comment in a draft general conformity analysis. Neither the DEIS nor the SDEIS provide a conformity analysis under 40 C.F.R. Part 93, despite the acknowledgement in the SDEIS that it is necessary.

SECTION 9: Recreation and Aesthetics Comments. The SDEIS identifies significant, but does not adequately analyze, impacts on boating opportunities and recreational experiences in Fort Collins. The SDEIS does not provide a full and complete evaluation of the aesthetics impacts from NISP. NEPA requires that the Corps further evaluate and provide additional information on those impacts so that Fort Collins and other stakeholders can meaningfully evaluate them.

SECTION 10: Biological Resources Comments. The SDEIS's unproven assertion that the Poudre River is on a trajectory of inevitable decline is contradicted by the facts. Neither NEPA nor the CWA allow agencies to disregard the impacts of proposed actions by assuming that

environmental resources will be lost regardless. The Poudre River Ecosystem Response Model and the Poudre River Health Assessment Framework can serve as effective guideposts and decision support tools for NISP. The SDEIS fails to include a quantitative temperature analysis, as noted above, which is needed to meaningfully analyze the impacts from NISP on aquatics and fisheries. The SDEIS also relies on oversimplifications and includes assertions that are not based on defined metrics. The SDEIS does not properly assess impacts to the Poudre River's wetlands and riparian areas (including its ground water component). The SDEIS further includes various incorrect assumptions, errors, and inappropriate conclusions, all of which result in under-quantification of the identified impacts of NISP on the Poudre River's wetlands and riparian areas. The SDEIS analyses of impacts to wildlife are inadequate because they are based on the flawed analysis for the Riparian and Wetlands sections of the SDEIS. The Corps must revise these so that Fort Collins and other stakeholders can meaningfully evaluate the impacts.

[Remainder of Page Left Blank Intentionally]

SECTION 1: INCORPORATION OF FORT COLLINS' COMMENTS TO DEIS

Fort Collins hereby incorporates by reference its comments on the original DEIS for NISP, including comments on the regulatory framework, which Fort Collins provided on September 10, 2008 ("2008 Comments"). The original DEIS contained flaws that rendered it insufficient under NEPA and the rules and regulations and guidelines thereunder, the CWA, and the rules and regulations and guidelines thereunder, and other relevant legal requirements.

The Corps has addressed some of the comments made by Fort Collins and other stakeholders. However, the SDEIS remains inadequate for the Corps to discharge its obligations under these requirements. Among flaws that carry over from the DEIS and identified in Fort Collins' DEIS comments are:

- Lack of compliance with the CWA requirement to analyze, avoid, and minimize impacts associated with NISP. *See* 2008 Comments at 13-17.
- Failure to provide adequate analysis (including modeling of water quality and other effects) at the DEIS stage. *See* 2008 Comments at 17-22. As discussed below, the SDEIS fails to provide the quantitative analyses of impacts it must provide.
- Failure to properly study and address effects of Total Organic Carbon ("TOC") levels in Horsetooth Reservoir. *See* 2008 Comments at 23-25.
- Flawed and incomplete analysis of the effects of the alternatives on lost peak flows and resulting impacts. *See* 2008 Comments at 26-28.
- Vague and insufficient avoidance, minimization, and mitigation planning and commitments. *See* 2008 Comments at 30-36.

These continuing flaws render the SDEIS inadequate and in violation of NEPA, the CWA, and other relevant legal requirements. As discussed below, the SDEIS also contains new flaws and inadequacies under those laws.

[Remainder of Page Left Blank Intentionally]

SECTION 2: VALIDITY OF THE NO ACTION ALTERNATIVE

2.1 THE NO ACTION ALTERNATIVE VIOLATES NEPA AND RENDERS ITS ALTERNATIVES ANALYSIS INVALID

The SDEIS's alternative analysis is flawed and violates NEPA. The analysis of alternatives under NEPA is "the heart of the environmental impact statement." *Or. Natural Desert Ass'n v. Bureau of Land Mgmt.*, 531 F.3d 1114, 1121 (9th Cir. 2008) (quoting 40 C.F.R. § 1502.14). In the SDEIS, the Corps must "[r]igorously explore and objectively evaluate all reasonable alternatives" to that action. 40 C.F.R. § 1502.14(a). An integral component of the alternatives analysis is the Corps' consideration of a no action alternative that serves as "a baseline for measuring the effects of the proposed action." *Biodiversity Conservation Alliance v. United States Forest Serv.*, 765 F.3d 1264, 1269–1270 (10th Cir. 2014). The no action alternative is a measuring stick that highlights the environmental impacts of the proposed action and allows them to be compared to the proposed action's benefit. Without a true no action alternative, there is no accurate baseline for measuring the effects of proposed action in the SDEIS. Thus, the current alternatives analysis for NISP is fundamentally flawed. To comply with NEPA, the alternatives analysis must be revised to include a true no action alternative that accurately serves as the baseline for its NEPA analysis.

2.1.1 The Proposed Cactus Hill Reservoir Requires a Section 404 Permit Under the CWA, and Therefore, Is an Action Under NEPA

Alternative 1 is developed around the proposed Cactus Hill Reservoir as a "no action" alternative. *See* SDEIS at 2-16. However, based on the information in the SDEIS and associated reports, Cactus Hill Reservoir requires a Section 404 permit under the CWA, 33 U.S.C. § 1344, and is an action that would therefore be subject to NEPA review. The treatment of Alternative 1 in the SDEIS as a no action alternative is thus improper and in violation of NEPA.

According to the SDEIS, the proposed Cactus Hill Reservoir component of the no action alternative would be a major construction project that will impact, among other things, 31.8 acres of wetlands, including 1.4 acres of wetlands impacted by fill discharges and 30.4 acres of wetlands that would be inundated by reservoir. *See* NISP Vegetation and Wetland Resources Technical Report at 13–14. Based on this information, Cactus Hill Reservoir would require an individual Section 404 permit and Alternative 1 is therefore an "action" under NEPA.

It is well-established that, under NEPA, the issuance of a Section 404 permit is an "action." *See, e.g., Ramsey v. Kantor*, 96 F.3d 434, 444 (9th Cir. 1996) ("If a federal permit is a prerequisite for a project with adverse impact on the environment, issuance of that permit does constitute major federal action and the federal agency involved must conduct an EA and possibly an EIS before granting it."). *See also Stewart v. Potts*, 996 F. Supp. 668, 672 (S.D. Tex. 1998) (stating that issuance of a Section 404 permit by the Corps is deemed to be a "major Federal action" to which NEPA's mandates apply). *See also, e.g.,* Daniel R. Mandelker, NEPA Law & Litig. § 8:19 (2d ed. 2014) (explaining that "[f]ederal permits" are "typical examples" of major federal action triggering NEPA). Based on the information in the SDEIS and the various technical reports, the treatment of

Cactus Hill Reservoir as a no action alternative—when the project would require a 404 permit and NEPA analysis—is arbitrary and capricious and violates NEPA.

If it is the Corps' position that Cactus Hill Reservoir would not require a Section 404 permit, then the Corps must provide a comprehensive explanation and factual basis for this conclusion—including a delineation of the wetlands on the proposed site of Cactus Hill Reservoir under the Corps' new "waters of the United States rule," 80 Fed. Reg. 37054 (June 29, 2015), and a demonstration why an individual Section 404 permit is unnecessary. The justification would be especially important here, because the Corps' entire alternatives analysis hinges on measuring the impacts of the proposed action against a major construction project with significant wetlands impacts.

The information provided in the SDEIS indicates that the estimated wetland impact caused by the Cactus Hill project would not fall within nationwide permits. For instance, Cactus Hill Reservoir's impacts exceed the Nationwide Permit 18's threshold requirements for minor discharges. 77 Fed. Reg. 10184 at 10202 (Feb. 21, 2012). Also, given that the Corps estimates that Cactus Hill Reservoir would impact 257 acres of wetlands and other waters (SDEIS at S-45), the Project would cause more than minimal individual and cumulative adverse effects on the aquatic environment and would require an individual permit. *See* 33 U.S.C. 1344(e). *See also* 77 Fed. Reg. at 10288.

As further example, the level of wetland impacts, both in terms of fill discharges (1.4 acres) and reservoir inundation (30.4 acres), for construction of Cactus Hill Reservoir for the no action alternative is more than the amount Fort Collins preliminarily estimated as being impacted from the enlargement of Halligan Reservoir, an action for which the Corps is requiring an individual Section 404 permit.

2.1.2 The Failure To Consider A Legitimate No Action Alternative Renders Its Alternatives Analysis Deficient under NEPA and the CWA

The use of Cactus Hill Reservoir as the no action alternative skews its entire analysis of alternatives, in violation of NEPA. The no action alternative is intended to "provide a baseline against which the action alternative" is evaluated." *Ctr. for Biological Diversity v. United States DOI*, 623 F.3d 633, 642 (9th Cir. 2010). Without "[accurate baseline] data, an agency cannot carefully consider information about significant environment impacts … resulting in an arbitrary and capricious decision." *N. Plains Res. Council, Inc. v. Surface Transp. Bd.*, 668 F.3d 1067,1085 (9th Cir. 2011). *See also Friends of Yosemite Valley v. Kempthorne*, 520 F.3d 1024, 1038 (9th Cir. 2008) (holding an agency's no action alternative in its NEPA analysis invalid because it improperly defined the baseline); *Openlands v. Dept. of Transport.*, No. 13 C 4950 (N.D. Ill., June 16, 2015)[1] ("The flawed 'no build' analysis also dooms the ROD and EIS'analysis of the direct effects of the proposed Corridor"; same with indirect impacts).

[1]https://scholar.google.com/scholar_case?case=5946396167037980773&q=ILLIANA&hl=en&as_sdt=4006&as_ylo=2015 (last visited August 6, 2015).

The SDEIS tables comparing alternatives illustrate the problem with treating Cactus Hill Reservoir as a no action alternative instead of an action alternative. In its comparison of alternatives, the SDEIS arbitrarily and simultaneously treats Cactus Hill Reservoir as both the no action alternative and as part Alternatives 3 and 4. SDEIS at 2-17, Table 2-3. *See also id*. 2-61. A "no action alternative in an EIS is meaningless if it assumes the existence of the very plan being proposed." *Friends of Yosemite Valley v. Scarlett*, 439 F. Supp. 2d 1074, 1105 (E.D. Cal. 2006). Because Cactus Hill Reservoir is an action that would have significant impacts requiring the Corps' review, it cannot serve as baseline against which the Corps' can compare the preferred alternative (Alternative 2). The consideration of Cactus Hill Reservoir's impacts as a consequence of no action, including environmental effects and financial costs, artificially reduces the significant impacts of the proposed action. This in turn precludes a meaningful alternative analysis and makes it "impossible to accurately isolate and assess the environmental impacts of the [proposed action]." *N.C. Wildlife Fed'n v. N.C. DOT*, 677 F.3d 596, 602 (4th Cir. 2012).

The no action alternative cannot include a project that requires a Corps permit and is an action under NEPA. The treatment of Cactus Hill Reservoir distorts the alternatives analysis and prevents the Corps, other agencies, and the public from "objectively evaluat[ing] all reasonable alternatives" to the proposed action. 40 C.F.R. § 1502.14(a). Further, in arbitrarily treating the Reservoir as both a no action alternative and as a major component of the Alternatives 3 and 4, the District fails to satisfy Section 404(b)(1) Guidelines' high burden imposed on projects that are not water dependent. Because the proposed action is not water dependent, the District must overcome presumption that practicable alternatives that do not involve impacting wetlands are available. *See* 40 CFR § 230.10(a)(3). To satisfy the Guidelines, the District must "clearly demonstrate" no practicable alternatives are available. *Id*. In treating Cactus Hill Reservoir as the no action alternative, the District has failed to rebut that presumption.

To comply with NEPA and the CWA, the Corps must conduct a reevaluation of the alternatives and present that information in a revised or second supplemental DEIS. And that analysis must include a true no action alternative that will serve as the baseline for an accurate and informed alternatives analysis.

[Remainder of Page Left Blank Intentionally]

SECTION 3: FAILURE TO CONDUCT ANALYSES ON ENVIRONMENTAL IMPACTS, FAILURE TO FULLY ADDRESS CUMULATIVE IMPACTS, AND UNCERTAINTY REGARDING MITIGATION MEASURES

3.1 THE FAILURE TO CONDUCT AND DISCLOSE ANALYSES ON CERTAIN ENVIRONMENTAL IMPACTS IN THE SDEIS VIOLATES NEPA AND THE CWA

Like the DEIS, the SDEIS defers critical environmental impact analyses to the final environmental impact statement ("FEIS") rather than providing them at the draft stage. For example, the SDEIS provides only incomplete and vague qualitative analysis of critical impact categories like water quality, as discussed further below. *See* SDEIS at 4-85 ("Results of Phase II water quality modeling will be presented in the FEIS") (emphasis added). Additional examples of such deferrals are included in the specific comments below, such as in Section 6.3.7 of these comments (No Analysis of Subsequent Exchanges Using Augmentation Program Flows). In deferring key analyses to a later date, the Corps violates NEPA's mandate that an agency timely "consider every significant aspect of the environmental impact of a proposed action" and "inform the public that it has indeed considered environmental concerns in its decisionmaking process." *Baltimore Gas & Elec. Co. v. Natural Res. Def. Council, Inc.*, 462 U.S. 87, 97 (1983). The SDEIS falls far short of satisfying either objective by failing to include in the SDEIS analyses of issues that are central to the evaluation of the proposed action.

CEQ regulations governing implementation of NEPA state that a draft impact statement "must fulfill and satisfy to the fullest extent possible the requirements established for final statements in [§ 4332(2)(C) of NEPA]." 40 C.F.R. § 1502.9 (emphasis added). Moreover, the regulations require that an insufficiently detailed DEIS be supplemented or revised: "if a draft statement is so inadequate as to preclude meaningful analysis, the agency shall prepare and circulate a revised draft of the appropriate portion." *Id*. (emphasis added). *See also N. Buckhead Civic Ass'n v. Skinner*, 903 F.2d 1533, 1540 (11th Cir. 1990) (it must be ensured that environmental effects will not be "overlooked or underestimated only to be discovered after resources have been committed or the die otherwise cast."). To comply with NEPA, the missing analyses must be conducted and included in a revised or second supplemental DEIS. Without that information, the Corps, other state and federal agencies, and the public cannot conduct a fully informed evaluation of NISP and its LEDPA.

3.1.1 A Hard Look at the Environmental Impact of NISP Has Not Been Taken Due to a Failure to Complete All Necessary Evaluations

NEPA "prohibits uninformed agency action." *Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 351, (1989). In preparing the SDEIS, a "hard look" at the environmental consequences of the proposed action and its impacts must be taken. The primary function of this detailed statement is to ensure "a fully informed and well-considered decision." *Vermont Yankee Nuclear Power Corp. v. Natural Resources Defense Council, Inc.*, 435 U.S. 519, 558 (1978). The "hallmarks of a 'hard look' are thorough investigation into environmental impacts and forthright acknowledgement of potential environmental harms." *Nat'l Audubon Soc'y v. Dep't of Navy*, 422 F.3d 174, 187 (4th Cir. 2005). Contrary to the principle that "accurate scientific analysis" is

"essential to implementing NEPA," *Sierra Club v. Van Antwerp*, 709 F. Supp. 2d 1254, 1259 (S.D. Fla. 2009), the SDEIS has substantial gaps that are claimed will be filled in later. Delaying environmental review that should be included in the SDEIS violates NEPA.

For example, in the SDEIS, only the qualitative analysis of water quality impacts is provided—stating, without explanation, that the quantitative analysis would be provided in the FEIS. *See* SDEIS at 4-85. The SDEIS indicates that modeling will be conducted to "facilitate the [CWA Section] 401 permitting process" in "coordination with the [Water Quality Control Division ("WQCD")] and the EPA using WQCD protocols." *Id*. at 4-153. However, the obligation to analyze and present impacts at the draft EIS stage is independent under NEPA. No sufficient reason is provided as to why this modeling cannot be completed and included in the SDEIS, or another draft document. WQCD Section 401 protocols are not needed to provide quantitative analysis of impacts in the SDEIS. The CWA Section 401 certification is a wholly separate federal process from the NEPA. It neither supplements the EIS, nor remedies flaws in the NEPA process stemming from the failure to provide the public with all relevant information on the impacts of NISP.

The incomplete analysis on water quality effects in the SDEIS undermines both the intent and expressed requirements of the NEPA. As stated above, NEPA is intended to ensure "accurate scientific analysis" and adequate public involvement. It prevents agencies from making decisions without timely and adequately analyzing the environmental impacts of a project. Thus, NEPA expressly mandates that if there is "incomplete information relevant to reasonably foreseeable significant adverse impacts [that] is essential to a reasoned choice among alternatives and the overall costs of obtaining it are not exorbitant, the agency shall include the information in the environmental impact statement. 40 C.F.R. § 1502.22. And that information should be provided in the draft EIS. *See* 40 C.F.R. § 1502.9. Here, the fact that plans exist to conduct the requisite water quality modeling at a later date demonstrate that the information is necessary and available; the analyses just need to be prepared. The failure to conduct water quality modeling and other relevant studies and include that information in the SDEIS violates NEPA.

3.1.2 The Failure to Conduct All Relevant Studies Violates NEPA's Requirement That The Public Is Fully Informed Of NISP's Environmental Effects

By deferring certain scientific analyses to a later date, the SDEIS does not satisfy NEPA's requirement that agencies "will have available, and will carefully consider, detailed information concerning significant environmental impacts, and that the relevant information will be made available to the larger [public] audience." *N. Idaho Cmty. Action Network v. U.S. Dept. of Transport.*, 545 F.3d 1147, 1153 (9th Cir. 2008). Because all relevant scientific analyses have not been conducted, the SDEIS is incomplete. In violation of NEPA, this lack of information prevents the "public and other government agencies [from] react[ing] to the effects of a proposed action at a meaningful time." *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 371 (1989). Stated another way, Fort Collins and others are not fully informed about the impacts of NISP, and cannot conduct meaningful review of the proposed action, if the SDEIS itself has not fully evaluated NISP.

Where, as here, the relevant information and scientific analyses are not available to the public for comment, the "[SDEIS] process cannot serve its larger informational role, and the public is

deprived of [its] opportunity to play a role in the decision-making process." *N. Plains*, 668 F.3d at 1085. As the Ninth Circuit states in *Pacific Rivers Council v. United States Forest Service*:

> The scope of its analysis of environmental consequences in [the] EIS must be appropriate to the action in question. NEPA is not designed to postpone analysis of an environmental consequence to the last possible moment. Rather, it is designed to require such analysis as soon as it can reasonably be done.

668 F.3d 609, 623 (9th Cir. 2012). Given the scope, complexity, and many environmental impacts of NISP, and the substantial and varied interests in the project, the Corps must fully assess and provide all relevant information on the impacts before making a decision. The failure to complete all the relevant studies and include them in the SDEIS is in violation of NEPA.

This is especially the case where Fort Collins made very clear in its comments on the DEIS how important water quality and riparian health are to Fort Collins, and Fort Collins informed the Corps that the analyses in the DEIS were vague and qualitative. The DEIS and SDEIS do not accomplish their purpose when they defer real analysis of some of the most critical issues needed for informed decision making.

3.1.3 There Is Insufficient Information to Determine Compliance With Section 404(b)(1) Guidelines and the CWA's Public Interest Review

The failure to conduct all necessary environmental analyses also violates the CWA. Under the Section 404(b)(1) Guidelines, a "permit cannot be issued if the proposed discharge will result in significant degradation of the aquatic ecosystem or if there is insufficient information to make a reasonable judgment as to whether the discharge will result in significant degradation. 40 C.F.R. §§230.12(a)(3)(ii), (iv)." *Utahns for Better Transportation v. USDOT*, 305 F.3d 1152, 1191 (10th Cir. 2002) (emphasis added). The failure to adequately consider (and expose to public scrutiny) the impacts associated with the proposed action is arbitrary and capricious under both NEPA and the CWA. *Id.* at 1192.

The inadequacies of the SDEIS demonstrate that Section 404(b)(1) Guidelines have not been complied with. To determine whether a proposed discharge will result in significant degradation, the 404(b)(1) Guidelines require detailed factual determinations regarding the effects of the discharge on the aquatic ecosystem. *Id.* at §230.10(c). *See also id.* § 230.11. Discharges that result in "significant degradation to waters of the United States" are also prohibited. 40 C.F.R. §230.10(c). Under the public interest review, a permit for NISP may not be issued if it is determined that doing so would be contrary to the public interest based on a "careful weighing" of the probable impacts of the project. 33 C.F.R. § 320.4(a). A "careful weighing" of environmental effects requires more information—including relevant quantitative analyses—than what is included in the SDEIS. Based on the current information in the SDEIS, the Section 404(b)(1) Guidelines and CWA's public interest review cannot be complied with.

3.2 FAILURE TO FULLY ADDRESS CUMULATIVE IMPACTS UNDER NEPA AND THE CWA

The SDEIS describes the cumulative impacts of NISP with the addition of Fort Collins' Halligan Water Supply Project ("Halligan Project") that includes the proposed enlargement of Halligan Reservoir, and the City of Greeley's proposed enlargement of Milton Seaman Reservoir. However, the SDEIS fails to disclose how the cumulative impacts will be evaluated with respect to each project. Of particular concern, as discussed below, is how responsibility for cumulative impacts from all three projects will be assessed to each project. As discussed above, such a deferral is not appropriate. *See Kern v. United States BLM*, 284 F.3d 1062, 1075 (9th Cir. 2002) (finding that it was not "appropriate to defer consideration of cumulative impacts to a future date when meaningful consideration can be given now").

Fort Collins is concerned that much of the assimilative capacity of the Poudre River to absorb certain impacts will be first apportioned to NISP because NISP is in an advanced stage of NEPA and CWA permitting relative to Fort Collins' and Greeley's respective projects. If true, Fort Collins is concerned that this approach would leave less assimilative capacity in the Poudre River for later analysis of the Halligan Project, which may lead to an exaggeration of streamflow impacts of the Halligan Project relative to an analysis in which the impacts of the Halligan Project are considered before the impacts of the NISP. This is especially concerning given that the streamflow impacts of the Halligan Project are expected to far less than NISP given the relative size difference between the two projects. For instance, the preferred alternative of the Halligan Project is the enlargement of Halligan Reservoir, which would be an increase of only 8,125 acre feet, which is significantly less than the volumes of all four NISP alternatives.

The SDEIS must provide information as to how the Corps intends to allocate assimilative capacity and all other cumulative streamflow impacts among the various Poudre River projects undergoing simultaneous NEPA and CWA permitting. Additional issues associated with cumulative impacts are discussed below.

3.3 UNCERTAINTY REGARDING MITIGATION MEASURES

It is Fort Collins' understanding that mitigation for NISP will be finalized with any Record of Decision ("ROD"), and that avoidance and minimization measures may be finalized before the ROD. As discussed further herein, Fort Collins notes that, at this point, the District's plans in these respects, which are summarized in Appendix F of the SDEIS, are conceptual and offer limited information on specific measures. Appendix indicates the intent of the District to recognize and react constructively to impairment of interests other than those of the District and the NISP participants, to be cooperative and responsive, and to participate in all reasonable efforts to address impairments to resources or interests caused by NISP. Where the document does not define specific limits or features of these commitments, however, it is of limited use except as a statement of general intent. *See Nat'l Audubon Soc'y v. Hoffman*, 132 F.3d 7, 17 (2d Cir. 1997) (holding an agency may rely on mitigation measures only when "the adequacy of proposed mitigation measures is supported by substantial evidence"); 40 C.F.R. § 230.75(d) (reliance on mitigation to be reasonable, the Corps' mitigation measures must "have been demonstrated to be effective in circumstances similar to those under consideration."). Clarification on these efforts is required by NEPA and the CWA.

As the entity most impacted by the Project, Fort Collins would welcome the opportunity to participate in mitigation-related discussion and efforts. After a complete assessment of the alternatives, Fort Collins urges that the proposed mitigation measures be demonstrated to be effective in minimizing the impacts of the proposed action.

[Remainder of Page Left Blank Intentionally]

SECTION 4: PROPOSED MODIFIED ALTERNATIVE 4

4.1 THE CORPS SHOULD CONSIDER FORT COLLINS' PROPOSED MODIFIED ALTERNATIVE 4

Fort Collins investigated a modified Alternative 4 for NISP ("Modified Alternative 4") that would meet the NISP Participant's purpose and need while simultaneously maintaining relatively more water in the Poudre River through Fort Collins than all other action alternatives presented in the SDEIS. Such additional flows through Fort Collins would address many of the concerns addressed in these comments.

The Modified Alternative 4 is proposed to operate in such a way as to significantly reduce NISP diversions upstream of Fort Collins as compared to Alternative 2 (the District's preferred action), as well as Alternatives 3 and 4, resulting in relatively more stream flows and relatively fewer impacts to aquatic and riparian resources along a 23 mile reach of river through Fort Collins than the other action alternatives considered in the SDEIS. This Modified Alternative 4 is expected to entail costs comparable with other alternatives and would also result in fewer wetlands impacts than all other alternatives described in the SDEIS. Hence, Modified Alternative 4 is a practicable alternative with fewer environmentally damaging impacts than those alternatives considered in SDEIS, and consequently should be evaluated by the Corps in its NEPA and CWA Section 404 analysis. Under NEPA and the CWA, the Corps must take a hard look at this proposed alternative. 40 C.F.R. § 1502.14(a); *id*. at § 230.10(a). The Corps must consider and, if shown to be practicable, choose Modified Alterative 4 as the least damaging practicable alternative. *Id.*

4.1.1 Summary of Alternative 4 in the SDEIS

Alternative 4 features Cactus Hill Reservoir with multiple diversion points. Alternative 4 functions similarly to both Alternatives 2 and 3, except that rather than all diversions occurring at the Poudre Valley Canal headgate upstream of Fort Collins, a portion of diversions are made downstream of Fort Collins at the New Cache Canal headgate. Specifically, Alternative 4 calls for all New Cache direct flow exchange water associated with the South Platte Water Conservation Project ("SPWCP") to be diverted at the New Cache Canal rather than the Poudre Valley Canal as is common in Alternatives 2 and 3. This modification results in more flow maintained in a 23 mile stretch of river, including the reach passing through Fort Collins, than Alternatives 2 and 3. For example, Alternative 4 results in flow reductions in June at the Canyon Gage that are 17% less than Alternative 2 and 31% than Alternative 3. *See* Water Resources Technical Report, Section 8.1.

The SDEIS does not explain why Alternative 4 only considers diversions of New Cache direct flow exchange water to Cactus Hill Reservoir at the New Cache Canal headgate rather than multiple other water sources associated with NISP. SDEIS Section 2.2.7.5 indicates that the SPWCP exchanges using the New Cache Canal and Larimer and Weld Canal were evaluated for downstream diversions in various ratios, and that Alternative 4 was configured after "specialists in fisheries, stream morphology, and water quality … concluded the scenario reflected in Alternative 4 provided the most environmental benefit." The SDEIS does not indicate that either the Grey Mountain Water Right or the SPWCP reservoir exchanges associated with Terry Lake, Big Windsor Reservoir, and Timnath Reservoir were considered for downstream diversion.

Diversions for Alterative 4 under the SPWCP exchanges at the New Cache Canal only represent 20-30% of the total Poudre River diversions for the Project (depending on alternative and run). For example, in Run 5a, such diversions at the New Cache Canal represent some 12,000 acre feet of the 42,000 acre feet of diversions. *See* Run 5a final Post-Poudre Basin Network Processor, file 5aPPP_20121004_FINAL.xls.

4.1.2 Summary of Fort Collins' Proposed Modified Alternative 4

Alternative 4 could be formulated to deplete less flow in the Poudre River through Fort Collins if other sources of water for the Project were delivered to Cactus Hill Reservoir via the New Cache Canal or the Larimer and Weld Canal with pump stations to Cactus Hill Reservoir. The Modified Alternative 4 entails the following concepts as summarized below.

Modified Alternative 4 is proposed to include the same general structural components as Alternative 4 (*i.e.*, Cactus Hill Reservoir, Galeton Reservoir, distribution pipeline network, use of Big Windsor Reservoir as a forebay, etc.), with the following three primary exceptions: (1) expansion and lining of the Poudre Valley Canal would not be needed nor occur; (2) pump stations from the New Cache Canal and Big Windsor Reservoir to Cactus Hill Reservoir would be expanded, and (3) an advanced water treatment plant, as formulated for the No Action Alternative, may be needed.

Under Modified Alternative 4, the Poudre Valley Canal would still be used to fill Cactus Hill Reservoir, but would function similarly to that proposed in the No Action Alternative and would not require expansion or lining. As a result of not lining the Poudre Valley Canal, Modified Alternative 4 would result in 47 fewer acres of wetlands downslope of the Poudre Valley Canal that could suffer permanently altered hydrologic support and 92 fewer acres of other waters that would be permanently filled as compared to Alternative 4. *See* SDEIS Summary, Section S.7.6. As a result, the Modified Alternative 4 would result in fewer wetland effects (34 acres) as opposed to the Alternative 2 (the District's preferred action) (65 acres). *See* SDEIS Summary, Table S-8.

Under the Modified Alternative 4, diversions under the Grey Mountain Water Right to Cactus Hill Reservoir of up to 200 to 250 cfs would occur via the Poudre Valley Canal. This flow rate is proposed as it is the existing capacity of the Poudre Valley Canal and is equivalent to the rate of Poudre Valley Canal diversions proposed for the No Action Alternative. Above this amount, any Grey Mountain Water Right diversions to Cactus Hill Reservoir would be made at the New Cache Canal with the water thereafter pumped to Cactus Hill Reservoir.[2]

[2] Fort Collins acknowledges that this would require approval of a change of water right for the Grey Mountain Water Right by the District Court, Water Division 1. *See, e.g.,* C.R.S. 37-92-305(3)(a). However, Fort Collins notes that the point of diversion for the Grey Mountain Water Right would be moved, in part, downstream (not upstream), and that, based on Fort Collins' current understanding, the contemplated draft of the Grey Mountain Water Right would not be expected to change. *See Twin Lakes Reservoir & Canal Co. v. City of Aspen*, 568 P.2d 45, 193 Colo. 478 (Colo. 1977); *City of Thornton v. Clear Creek Water Users Alliance*, 859 P.2d 1348 (Colo. 1993). Such a change would thus not be anticipated to adversely affect the Grey Mountain Water Right. Provided that such a proposed change of water right

Based on Grey Mountain Water Right yields from Run 5a modeling and assuming a 200 cfs inflow capacity to Cactus Hill Reservoir from the Poudre Valley Canal, Modified Alternative 4 would result in approximately half of Grey Mountain Water Right yields being diverted each at the Poudre Valley Canal and the New Cache Canal. *See* Run 5a final Post-Poudre Basin Network Processor, file 5aPPP_20121004_FINAL.xls. Again using Run 5a modeling, it is estimated that overall, diversions to storage at the Poudre Valley Canal would be approximately 15-20% of the amount anticipated under Alternative 2. Additional modeling would be needed to determine specifics, but it is logical that the reduced Poudre Valley Canal diversions would thus translate to substantially more flow in the Poudre River downstream of the Poudre Valley Canal as compared to Alternative 2. This would substantially reduce the impacts to water quality, riparian health, wetlands and other impacts downstream of the Poudre Valley Canal relative to Alternative 2, as discussed in the 2008 Comments and these comments. It is assumed that diverting some water through the Poudre Valley Canal is needed to improve water quality in Cactus Hill Reservoir, and is reasonable considering that expanding and relining the Poudre Valley Canal would not be necessary for Modified Alternative 4. Additional study by the Corps would be needed on the amount and timing of Poudre Valley Canal diversions under the modified alternative as these diversions would have the benefit of improving water quality in Cactus Hill Reservoir, but the detriment of depleting Poudre River stream flow.

The Modified Alternative 4 further proposes that a majority of Poudre River diversions associated with the SPWCP would be made at the New Cache Canal headgate rather than at the Poudre Valley Canal. The Modified Alternative 4 proposes that all New Cache direct flow exchange water and all exchange water associated with Terry Lake and Timnath Reservoir be diverted at the New Cache headgate for delivery to Cactus Hill Reservoir. In order to reduce pumping and improve water quality in Cactus Hill Reservoir, it is likely desirable to make some diversions under the SPWCP exchanges at the Larimer and Weld Canal headgate for delivery to Big Windsor Reservoir with subsequent pumping to Cactus Hill Reservoir. Therefore, under Modified Alternative 4, it is conceptually assumed that 50% of the Larimer and Weld direct flow exchange water and 50% of Big Windsor Reservoir exchanges under the SPWCP would be diverted at the New Cache Canal headgate. Additional study by the Corps would be needed to determine the exact ratio of Larimer and Weld diversions at each diversion location under the modified alternative weighing improvements to water quality in Cactus Hill Reservoir with the detriments of depleting a longer reach of the Poudre River.

By diverting SPWCP exchange water further downstream at the New Cache Canal, additional flow will be maintained in the Poudre River between the originally proposed diversion point and the New Cache Canal. In the case of Larimer and Weld direct flow exchange water and SPWCP reservoir exchanges associated with Terry Lake, Big Windsor Reservoir, and Timnath Reservoir, by diverting this water further downstream flows would be improved between the current diversion locations and New Cache headgate above baseline conditions. As such, Modified

---

were shown to not adversely affect Fort Collins' water rights, Fort Collins would likely not oppose such a change of the Grey Mountain Water Right.

Alternative 4 could even improve flows in places and times through Fort Collins above what is observed in the current baseline without any mitigation or augmentation flows.

The diversions to Cactus Hill Reservoir detailed above would result in far fewer flow impacts along a 23 mile reach of the Poudre River than any other action alternative examined in the SDEIS. Consequently, the Modified Alternative 4 may not require a flow augmentation program similar to that proposed by the District for Alternative 2.

4.1.3 Other Considerations for Modified Alternative 4

Under the Modified Alternative 4, water quality in Cactus Hill Reservoir is preliminarily predicted to be comparable to the water quality predicted in Cactus Hill Reservoir for the No Action Alternative, but worse than predicted for either Glade Reservoir for Alternative 2 or Cactus Hill Reservoir for Alternatives 3 and 4, especially in terms of total dissolved solids ("TDS"). Using water quality data from the SDEIS (SDEIS Tables 4-32, 4-37, and 4-39) and predicted relative flow contributions by diversion location, the TDS conceptually predicted for Cactus Hill Reservoir in the Modified Alternative 4 is 350-400 mg/L, which is below the 500 mg/L maximum containment limit and the 400 mg/L upper limit goal used for developing the No Action Alternative in the SDEIS. *See* page 4 of Technical Appendix: NISP No Action Alternative Evaluation. However, with such high TDS it is assumed (similarly to the No Action Alternative) that NISP Participants would construct advanced water treatment facilities.

Diversions at the New Cache Canal headgate are downstream of wastewater treatment plant discharges, which raise certain water quality concerns both for users of Cactus Hill Reservoir and wastewater effluent dischargers. It is likely that the Modified Alternative 4 would lead to a Total Maximum Daily Load process and limitations for nutrients associated with wastewater discharges, such as those made by Fort Collins, above diversions to Cactus Hill Reservoir at the New Cache Canal.

Under the Modified Alternative 4, annual pumping inputs would be greater than any other alternative in the SDEIS due to the relatively larger pumping head required to fill Cactus Hill Reservoir from the New Cache Canal. However, pumping costs are not so large as to preclude the viability of Modified Alternative 4. For example, and as a worst case scenario, it is conceptually estimated that if all inflows to Cactus Hill Reservoir were taken at the New Cache Canal the total energy requirement would be roughly 80,000,000 to 85,000,000 KW-hr. This amount may be compared to 64,400,000 KW-hr for Alternative 4 and 48,100,000 KW-hr for Alternative 2 under the Reclamation Action Option or 61,300,000 for Alternative 2 under the No Reclamation Action Option. *See* SDEIS Summary, Table S-10. Diverting all inflows to Cactus Hill Reservoir at the New Cache Canal exceeds that which is proposed for Modified Alternative 4, but was analyzed as a worst case scenario for illustrative purposes. Under this worst case scenario, total annual pumping power costs for Modified Alternative 4 are expected to be, at a maximum, roughly $6,000,000, as opposed to $4,511,000 for Alternative 4, $4,291,000 for Alternative 2 without Reclamation Action, and $2,663,000 for Alternative 2 with Reclamation Action (from SDEIS Table 2-12). Worst case energy and cost estimates for Modified Alternative 4 were developed with available information summarized SDEIS data and are conceptual in nature. Given that Modified Alternative 4 would

likely have significantly less environmental impact than the SDEIS alternatives, including fewer wetlands and streamflow impacts along a vital 23 mile reach of Poudre River, it remains a practicable alternative, even in light of the approximated higher pumping costs. Further, the difference in pumping costs between Modified Alternative 4 and the other alternatives is small relative to the overall costs of the proposed action.

Because of the increased pumping inputs required for Modified Alternative 4, greenhouse gas emissions associated with pumping are anticipated to be greater than any other SDEIS alternative, which may exacerbate NISP's climate change impacts, which are discussed in Section 8 of these comments. Nevertheless, given that the proposed Modified Alternative 4 will have far fewer aquatic impacts than other SDEIS alternatives, including fewer impacted wetlands and fewer streamflow impacts along a vital 23 mile reach of Poudre River, the increased greenhouse gas emissions associated with larger pumping inputs may be justified, especially given that increased greenhouse gas emissions could be avoided, minimized, or mitigated, for example, by the use of renewable energy sources or by employing other climate change mitigation methods.

Total capital costs for Modified Alternative 4 are expected to be comparable to Alternative 4 costs provided in the SDEIS. Although additional costs are required for upgrading the New Cache Canal pumping facilities and potentially for advanced water treatment, large cost savings are realized from not having to expand and line a 30 mile section of the Poudre Valley Canal. Using costs provided in the SDEIS (SDEIS Table 2-12), it is conceptually predicted that the Modified Alternative 4 would have a capital cost of roughly $700,000,000. This amount is 38% more than the Alternative 2 with Reclamation Action, but only 6% more than Alternative 2 without Reclamation Action. Furthermore, mitigation costs will likely be less for Modified Alternative 4 than other alternatives given that the environment impacts will be less. Cost estimates for the Modified Alternative 4 were developed with summarized SDEIS data and are conceptual in nature. Accordingly, Fort Collins urges the Corps to satisfy its legal obligation under NEPA and to take a hard look at Modified Alternative 4.

[Remainder of Page Left Blank Intentionally]

SECTION 5: WATER QUALITY COMMENTS

The SDEIS describes three major water quality impacts of interest to Fort Collins, as discussed in detail below: (1) degradation of raw source water quality delivered to the Fort Collins Water Treatment Facility ("FCWTF"); (2) degraded water quality or flow regime changes on Poudre River Segments 10a, 10b, and 11; and (3) degraded water quality or flow regime changes on the wastewater discharge permits issued for Fort Collins' two water reclamation facilities ("Drake WRF" and "Mulberry WRF").

The SDEIS was also issued without several quantitative analyses that are necessary for the Corps to take a hard look at water quality impacts required NEPA and the CWA. Without this information, the Corps cannot make a "fully informed and well-considered decision." *Vermont Yankee*, 435 U.S. at 558. Also, the lack of analyses prevents Fort Collins from meaningfully understanding the possible effects on its interests. To comply with NEPA, the Corps must analyze the antidegradation regulations for the Drake and Mulberry WRFs and conduct temperature modeling and water quality modeling for the Poudre River.

The FCWTF currently receives water from two sources: Horsetooth Reservoir (by direct connection) and Poudre River water routed through the Fort Collins Pipeline and Pleasant Valley Pipeline ("PVP"). The PVP is a pipeline (separate from the Fort Collins Pipeline) that runs from the Munroe Canal to the FCWTF. Fort Collins also shares use of the PVP with other entities, including the Fort Collins-Loveland Water District, which uses the PVP to deliver water to the Soldier Canyon Treatment Plant. Under Alternative 2 with the Reclamation Action Option, both of Fort Collins' raw water sources would be affected adversely. Residence times in Horsetooth Reservoir would be substantially increased resulting in poorer water quality in Horsetooth Reservoir. As discussed below, Glade Reservoir water may be of lower quality than Poudre River water due to long hydraulic residence times in that reservoir, and would be delivered through the PVP to the Soldier Canyon Treatment Plant, adversely affecting Fort Collins' Poudre River water run through the PVP. It is reasonably foreseeable that both changes would require Fort Collins to perform increased water treatment that will be costly for Fort Collins to install and operate.

Alternative 2 will affect the Poudre River by diversions into Glade Reservoir decreasing flushing flows and Glade Reservoir releases back to the river during the warm months that will impact water quality. Flushing flows remove algal biomass and excess sediment from the river bottom. Reduction of these high flows could lead to development of large algal mats and island formation.

Glade Reservoir water has the potential to be higher in certain water quality constituents (TOC, iron, manganese, nitrogen, phosphorus) than water currently released from Horsetooth Reservoir to the Poudre River. It is reasonably foreseeable that increases in regulated constituents in the river upstream of Fort Collins' permitted discharge points would lead to exceedances of standards in the river and exceedances of effluent limits in the mixed flow downstream of the discharge point. For the downstream mixed flow, reductions in river flow combined with upstream increases in regulated constituents will make exceedances of standards more likely.

5.1 COMMENTS REGARDING INCOMPLETE ANALYSES RELATED TO WATER QUALITY

5.1.1 No Analysis of Antidegradation Regulations and Mulberry and Drake WRFs

SDEIS Section 4.3.10 401, Certification Process and Antidegradation Review

> Statement: *"The WQCC is responsible for issuing Water Quality Certifications under Section 401 of the CWA for projects or actions that are applicable to the provisions of the Colorado 401 Certification Regulation (WQCC Regulation #82: 5 CCR 1002-82). […] The 401 certification process is a permitting requirement separate from NEPA compliance. 401 certification and antidegradation review will be required for any permitted alternative prior to construction. To facilitate the 401 permitting process, additional water quality modeling will be conducted for the FEIS in coordination with the WQCD and the EPA using WQCD protocols. The intent of this effort is to use the results of the water quality analysis conducted for 401 certification in the FEIS and thus, minimize any duplication of effort."*

Comment: The SDEIS does not address the effects of NISP on Mulberry and Drake WRF facilities' compliance with antidegradation regulations, which are based on maintenance of historical water quality and not solely on water quality standards. Fort Collins thus cannot meaningfully analyze NISP's effects in this respect.

NEPA and the CWA require that the Corps address indirect effects of the proposed action. *See* 40 C.F.R. § 1508.8(b). *See also id*. § 230.11(h) (requiring consideration of "secondary effects"). Further, the Corps' guidelines prohibit a discharge that causes or contributes to violations of any state water quality standards. *See* 40 C.F.R. § 230.10(b)(1). Thus, the Corps must conduct additional studies and analyses in these proceedings with respect to the compliance of Mulberry and Drake WRF facilities with antidegradation regulations.

5.1.2 No Analysis of Chlorophyll

SDEIS Section 4.4.3.1.1, Poudre River, Flows and Flooding

> Statement: *"Laporte Reach. Flood flows are predicted to be reduced. […]Fort Collins and Upper Timnath Reaches. There is a predicted 20% to 35% reduction in flow duration at or above 1,000 cfs, as well as a 20% to 40% reduction in the duration of flows in the interval from 140 cfs to 1,000 cfs. […] For the 26-year period of record, 23 flushing events under Current Conditions lasting for 325 days in total would become 16 flushing events under Alternative 2 lasting for 222 days in total."*

Comment: Amounts of attached algae in streams (measured as chlorophyll) are currently regulated by the State of Colorado under Section 31.17 of Regulation 31 of the Water Quality Control Commission, 5 CCR 1002-31, under interim values, and the use of these interim values will be used in the adoption of water quality standards prior to May 31, 2022. Flow velocity exercises strong control over chlorophyll accumulation in stream channels. The SDEIS does not assess the impact of reduction of flow volumes and flow velocities on chlorophyll development. Fort Collins thus cannot judge and meaningfully analyze the effects on Fort Collins.

The Corps must analyze all NISP alternatives' impact on chlorophyll accumulation. This is essential both for NEPA and the CWA prohibition on fills that would cause or exacerbate any violation of water quality standards.

5.1.3 No Quantitative Analysis of Temperature

SDEIS Section S.1.2.2, Planned Activities After SDEIS Issuance

Statement: *"Before FEIS issuance, or issuance of a Record of Decision as noted, the Corps anticipates completing the following activities: […] Complete Phase II water quality and stream temperature modeling in coordination with the WQCD and the EPA using WQCD protocols."*

Comment: The SDEIS states that temperatures within the Poudre River will be higher as a result of the operation of NISP, but does not offer quantitative projections that would allow Fort Collins to meaningfully analyze the likelihood that specific stream sections now in compliance with State standards for temperature for protection of aquatic life will become noncompliant as a result of the project.

As discussed above, an "accurate scientific analysis . . . and public scrutiny are essential to implementing NEPA." 40 C.F.R. § 1500.1. The Corps' deferring analyses violates NEPA's requirement that agencies "will have available, and will carefully consider, detailed information concerning significant environmental impacts, and that the relevant information will be made available to the larger [public] audience." *N. Idaho Cmty. Action Network*, 545 F.3d at 1153. Without temperature data, Fort Collins and other stakeholders cannot meaningfully review temperature impacts. Thus, the Corps must supplement or revise the SDEIS to include a quantitative analysis of temperature for all alternatives, and the Corps must afford Fort Collins and others an opportunity to review and comment on that information. Because this is a critical water quality attribute, appropriate analysis is necessary to comply with the CWA. *See* 40 C.F.R. § 230.10(b).

5.1.4 No Quantitative Analysis of Water Quality Effects Below Glade Reservoir

SDEIS Section S.7.2, Surface Water Quality

Statement: Table S-6. Potential for exceedance of water quality standards.

Parameter	Alternative 2	Alternative 3	Alternative 4
Poudre River above Lincoln Street in Fort Collins (Segment 10)			
Copper	Medium	Medium	Medium
Dissolved Manganese	Medium	Medium	Medium
Poudre River from Lincoln Street to below Boxelder Creek (Segment 11)			
Total Phosphorus	Medium	Medium	Medium
Selenium	High*	High	High
Poudre River from below Boxelder Creek the South Platte River (Segment 12)			
Total Recoverable Iron	High*	High*	High*
Ammonia	High*	High*	High*
Total Phosphorus	High*	High*	High*
Selenium	High*	High*	High*
Segment 1b of the South Platte River			
Total Recoverable Iron	High*	High*	High*
Dissolved Manganese	Medium	Medium	Medium
Ammonia	Medium	Medium	Medium
Total Phosphorus	High*	High*	High*
Sulfate	High*	High*	High*

*Water Quality Standard already being exceeded under current conditions.

SDEIS Appendix F, Section 4.4.1, Glade Reservoir Water Quality Enlargement (FW-06)

Statement: "*Northern Water proposes to evaluate an increase in Glade storage to as much as 192,500 acre-feet to allow for operational flexibility during the late summer period. This would include the following tasks to be completed between the SDEIS and FEIS, so that the Corps permit decision can include a potential water quality enlargement of Glade Reservoir:*

- *Verification through the use of full CTP hydrology and modeling that an increase in storage can off-set the lack of diversion during late summer while still meeting full project yield.*
- *Integration of the detailed water quality modeling with the refined configuration and determination of potential operational strategies for mitigation of effects or environmental enhancement, including the evaluation of temperature thresholds above which NISP diversions may be curtailed.*
- *Validation by the third party contractor that no significant adverse environmental consequences are caused by either the enlargement of Glade or the change in inflow pattern.*"

Comment: The SDEIS forecasts adverse water quality effects of NISP on the Poudre River below the point of diversion for Glade Reservoir but omits quantitative predictions, which are stated to be given only in the FEIS. Therefore, Fort Collins and other affected parties cannot judge or meaningfully analyze whether impairments will lead to new violations of water quality standards as reflected in 303(d) listing of impaired waters by the State of Colorado. Details regarding the proposal to enlarge the capacity of Glade Reservoir to accommodate water quality needs are not given. The changes in stream flows and associated resource impacts from enlarging Glade Reservoir must be fully described and analyzed.

As stated above, NEPA requires that the Corps conduct a quantitative analysis of water quality impacts below Glade Reservoir and provide that information in the SDEIS to Fort Collins and other stakeholders. *See* 40 C.F.R. §§ 1502.22, 1502.9. This analysis is also essential for compliance with the Corps' obligation to avoid causing or exacerbating violations of water quality standards. *See* 40 C.F.R. § 230.10(b).

5.1.5 Water Quality Monitoring Is Not Mitigation

SDEIS Appendix F, Section 4.4.3.2, Water Quality Monitoring

Statement: *"Additional water quality monitoring would be performed to more fully characterize and understand the effects of NISP operations on Poudre River water quality before and after NISP project components are built and implemented, and to meet the water quality commitments of this Conceptual Mitigation Plan. […] Initial data collection […]Long-term monitoring […] The final sites, parameter list, and frequency for the initial data collection effort will be determined between the SDEIS and FEIS based on the analyses and modeling being conducted for the FEIS and State 401 water quality certification process."*

Comment: The only specific action item in the mitigation plan addressing water quality impacts is a water quality monitoring program. Monitoring, without potential actions based on the monitoring, does not compensate for or mitigate unavoidable impacts. The conceptual mitigation plan fails, at this point, to address important water quality issues in Segment 11, where dilution water quantity and quality are critical to compliance with water quality standards and antidegradation rules. Water quality maintenance in this reach requires commitments to minimum flows sufficient to insure adequate dilution of wastewater effluent. Low flow augmentation commitments are based on availability of water at the point of augmentation and not through the downstream reaches. This

problem needs to be addressed explicitly with reference to the two wastewater treatment plants for the City (Mulberry and Drake WRFs).

As stated above, the SDEIS water quality assessment lacks key quantitative analyses. Under NEPA and the CWA, proposed mitigation measures dependent on incomplete environmental impact analyses fail. *Ohio Valley Envtl. Coalition v. United States Army Corps of Eng'rs*, 479 F. Supp. 2d 607, 627 (S.D. W. Va. 2007). Stated another way, the Corps' purported mitigation in the form of monitoring is inherently inadequate because it is based on only a portion of the required water quality analyses. Any mitigation for NISP must directly address the impacts discussed herein.

5.2 COMMENTS REGARDING IMPACTS TO SOURCE WATER QUALITY FOR THE FCWTF

5.2.1 Changes to Hydraulic Residence Time in Horsetooth Reservoir

SDEIS, Sections 2, 3, and 4

Statement: Page 2-41: *"Horsetooth Reservoir releases an average of nearly 60,000 AF to the Poudre River each year."*

Statement: Page 3-27: *"C-BT deliveries to the Poudre River from Horsetooth Reservoir via the Hansen Supply Canal averaged nearly 75,700 AFY for the period including WY 1952-2009 (CDM Smith, DiNatale, and Hydros 2011)."*

Statement: Page 4-41: *"In addition to these releases to the Poudre River and the Poudre Valley Canal, Glade Reservoir under the Reclamation Action Option would release an average of 10,500 AFY for direct delivery to the water treatment facilities for Participants FCLWD, Evans, Eaton, Severance, and Windsor (see the 2014 Operations Report, Section 5.1.1.1). Potential pumping from Glade Reservoir to Horsetooth Reservoir (see Section 4.2.3.3.3) would average about 400 AFY (averaged over 56 years)."*

Statement: Page 4-46: *"Horsetooth Reservoir releases averaged 51,300 AFY, with 49,500 AFY released to the Poudre River and 1,800 AFY delivered to the Poudre Valley Canal via the Windsor Extension. Under NISP Alternative 2 with the Reclamation Action Option, Horsetooth Reservoir releases would be reduced to 21,900 AFY (20,200 AFY to the river and 1,700 AFY via the Windsor Extension)."*

Comment: The planned decreases in the release of water from Horsetooth Reservoir (from 51,300 to 21,900 acre feet per year) will lead to a substantial increase in hydraulic residence time for water in Horsetooth Reservoir. Under operational scenarios proposed in this SDEIS, the historical average residence time of 2-3 years could become about 7 years. Increased residence time for reservoirs in Colorado often is associated with increased algal biomass and change in algal community composition in the upper mixed layer of the reservoir during water column stratification season. *See* Northern Water, 2014 Water Quality Stakeholders Meeting: 2013 Three Lakes Water Quality and Operations, or Why Did Shadow Mountain Turn Green, dated March 4, 2014. An increase in algal production and changes in community composition in Horsetooth Reservoir could potentially result in increases in TOC concentrations, more frequent occurrence of elevated concentrations of taste and odor compounds such as geosmin and 2-methylisoborneol (MIB), as well as an increased likelihood of cyanotoxin production. Each of these issues poses significant concern for the FCWTF and would

potentially require new and/or costly monitoring and treatment solutions that are currently not required, including the use of powdered or granular activated carbon.

As described in Fort Collins' comment regarding SDEIS Section 4.3.4.5 Effects on Water Treatment Plant Operations, the proposed increase in hydraulic residence time in Horsetooth Reservoir was not included in the modeled scenarios for the SDEIS. As such, it is not possible to evaluate the combined effects of increased hydraulic residence time and possible inflows from Glade Reservoir on algal abundance or TOC concentrations, or to estimate the likelihood of algal metabolites production like geosmin, MIB or cyanotoxins. Without this information, the FCWTF remains vulnerable to unexpected and substantial costs associated with new or enhanced treatment costs.

The City has identified ozone/advanced oxidation as the water treatment solution needed to manage regular occurrence of cyanotoxins and/or taste and odor compounds like geosmin and MIB in the Horsetooth raw water supply. *See* CH2M. 2015. Technical Memorandum: Revised Costs for Impacts to Water Treatment Operations Resulting from NISP Operations. August 6, 2015 ("Costs Report"), which is provided with these comments. Capital costs associated with this type of advanced treatment are estimated at $26.9 million, in 2015 dollars, with an annual operating cost of $703,000. Likewise, the ozone/advanced oxidation is the treatment solution proposed for managing persistent taste and odors issues, with the same capital and annual operating costs.

Additionally, the use of granulated activated carbon may be required in the event that concentrations of TOC in Horsetooth Reservoir increase to 5-6 mg/L on a consistent basis and enhanced coagulation fail to reduce TOC to needed levels. The capital costs associated with a new organics removal facility are $72.9 million and annual costs of $2.5 million, in 2015 dollars. *See* Costs Report. Although the application of granular activated carbon is not considered necessary under the scenario of a 0.5 mg/L increase in average TOC concentrations, as reported in the SDEIS, such measures may become necessary in the event that the proposed changes in hydraulic residence time result in TOC concentrations consistently above 5-6 mg/L. As stated previously, the information presented in the SDEIS is not adequate for addressing this likelihood.

Longer hydraulic residence time also can lead to greater extremes of hypolimnetic oxygen loss, which facilitates the release of dissolved iron and manganese from bottom sediments (Dortch 1997). Dissolved iron and manganese precipitate when oxygenated upon release from the hypolimnion. The precipitate forms particles and coatings that interfere with water treatment. Taste and odor problems may also be caused by anoxic water even after aeration. These issues related to prolonged hypolimnetic oxygen depletion would likely result in additional treatment costs from increased chemical usage specifically, pre-oxidation with chlorine dioxide to manage manganese and iron issues at an estimated peak daily cost of $2,109, or a weekly cost of $14,765, and/or the use of powdered activated carbon (PAC) to remove taste and odor compounds. *See* Costs Report.

If, due to NISP, TOC concentrations in Horsetooth Reservoir reach a level that the FCWTF cannot treat without installing additional treatment facilities, Northern must be required to pay for installation and operation of a pretreatment facility to remove some TOC from raw source water before it enters the FCWTF. If taste and odor compounds or cyanotoxin concentrations reach a

problematic level, Northern must deliver treatable water to the FCWTF that can be used until the water quality in Horsetooth Reservoir reaches a treatable status. In addition, if Horsetooth water quality is degraded to the point that it is not usable for more than 6 months, Northern must be required tp pay for constant forced destratification. Mixing could reduce the amount of greenhouse gasses that would normally be released from the reservoir during stratification.

The CWA requires the Corps to take hard look at the potential negative changes in the water quality of Horsetooth Reservoir caused by the proposed action. Specifically, the Section 404(b)(1) Guidelines prohibit any discharge that would cause or contribute to "significant degradation of the waters" or "violations of any applicable State water quality standard . . . ." 40 C.F.R.§ 230.10(b)(1), (c). These impacts include "secondary effects" caused by the project including the impacts discussed above. 40 C.F.R. § 230.10(h). Additionally, NEPA requires the Corps to address "reasonably foreseeable" impacts and emphasizes the importance of taking a hard look at uncertain effects:

> [I]n the ordinary course of business, people do make judgments based upon reasonably foreseeable occurrences. . . . The agency has the responsibility to make an informed judgment, and to estimate future impacts on that basis, especially if trends are ascertainable . . . . The agency cannot ignore these uncertain but probable, effects of its decisions.

46 Fed. Reg. at 18031. Given the potentially significant impacts on water quality in Horsetooth Reservoir, and the potential costs that would be incurred by Fort Collins to address those impacts, the Corps must assess the potential impacts and mitigation measures discussed above.

5.2.2 Hydraulic Residence Time in Glade Reservoir and the PVP

SDEIS Section 2.5.4.1, Glade Reservoir

Statement: *"The modeled hydraulic residence time (the length of time diverted water would remain in the reservoir) would be 4.6 years."*

Comment: Under operating conditions described in the SDEIS, Glade Reservoir will experience long hydraulic residence times. The water quality effects of long residence times in Glade Reservoir are expected to be similar to those described above for Horsetooth Reservoir. As such, Glade Reservoir water has the potential to be higher in certain water quality constituents (TOC, iron, manganese, nitrogen, phosphorus) than water currently released from Horsetooth Reservoir to the Poudre River. Increases in regulated constituents in the river upstream of Fort Collins' permitted discharge points could lead to exceedances of standards in the river and exceedances of effluent limits in the mixed flow downstream of the discharge point. For the downstream mixed flow, reductions in river flow combined with upstream increases in regulated constituents will make exceedances of standards more likely. Furthermore, Glade Reservoir water delivered through the PVP to the Soldier Canyon Treatment Plant may adversely affect Fort Collins' Poudre River water running through the PVP.

Water storage in Glade Reservoir will lead to differential water quality conditions in the upper and lower portions of the water column during the season of water column stratification. A multiple outlet structure will be available for Glade Reservoir so that selective water withdrawal is possible. This measure may not be sufficient, however, to protect the quality of waters released from the reservoir because of the simultaneous occurrence of impairment of the upper water column (high temperature, algae) and lower water column (iron, manganese, organics) during the season of stratification. Release of water from points below the epilimnion of Glade Reservoir during the summer for purposes of maintaining low temperature or avoiding algal biomass in the epilimnion are complicated by the likely presence of substantial concentrations in the release water of dissolved iron and manganese that will precipitate as oxides and hydroxides upon entering the river. (Dortch 1997, Smith 1982). It can be assumed that the engineered release structure will reoxygenate the water, but the problem of chemical precipitation is not dealt with in the mitigation plan.

The mitigation for Alternative 2 must include commitment to and measures ensuring constant destratification of Glade Reservoir in the event that water quality problems resulting from stratification are observed or expected. Mixing could reduce the amount of greenhouse gasses that would normally be released from the reservoir during stratification.

5.2.3 Glade Reservoir Forebay Water Quality Issues

SDEIS Section 2.5.4.1, Glade Reservoir

Statement: "*A forebay and pump station would also be constructed southwest of the reservoir.*"

Comment: The SDEIS describes the building of a forebay in front of the dam, but not the operation of the forebay. Under certain operational scenarios, it is reasonably foreseeable that water could be released directly from the forebay into the PVP and/or the Poudre River. The forebay is a small waterbody that is hydrologically separated from Glade Reservoir. The quality of the water in the forebay will vary greatly based on factors such as hydraulic residence time, degree of drawdown, and quality of source water. Waters of the forebay may be subject to warming, wind generated turbidity, or algal blooms to a degree that would not be expected in Glade Reservoir. As a result, downstream uses could be impaired if water is released directly to the river from the forebay.

If the Corps approves NISP, the Corps must include permit conditions prohibiting any release of forebay water directly into the PVP or the Poudre River under any conditions. If the Corps does not prohibit releases, then it must adequately assess the potential impact releases of the forebay water.

5.2.4 Glade Reservoir Water Quality During the Initial Fill

SDEIS Section 4.3.4.1.1, Projected Reservoir Water Quality, Glade Reservoir

Statement: *"Water quality during initial reservoir filling would be affected by the release of nutrients and organic matter in the soil. During this period water quality may be impaired by high suspended solids, elevated nutrient concentrations, and potentially high concentrations of algae (Lewis 2003)."*

Comment: The SDEIS recognizes that Glade Reservoir, when in the filling phase, may show water quality problems that are associated with early stabilization of the reservoir. The SDEIS commits to withholding water in the reservoir from use for a specific period of time to allow for stabilization of reservoir water quality.

If the Corps approves NISP, it must require as a permit condition that the District commit to measures for extending the withholding period as necessary to prevent impairment of downstream waters to a degree that would not be expected over the long term, i.e., the startup period during which waters are withheld must not be defined by elapsed time, but rather by water quality conditions in the reservoir.

5.2.5 Use of the PVP to Deliver Water From Glade Reservoir

SDEIS Appendix F, Section 3.2.1, Avoid Munroe Canal Diversions (FW-01)

Statement: *"The original Draft EIS considered using the Munroe Canal for two operations associated with NISP. […] The exchange has been eliminated in the SDEIS analysis, and replaced with a new pipeline directly from Glade Reservoir to the Pleasant Valley Pipeline (for Fort Collins-Loveland Water District) and a new pipeline directly from Glade Reservoir to the Soldier Canyon Filter Plant (for Eaton, Severance and Windsor)."*

Comment: The proposed use of the PVP to convey deliveries of water from Glade Reservoir creates potential water quality issues, as described above.

Due to potential degradation of water quality caused by Alternative 2, these releases must be required to be made through a second pipeline rather than through the PVP, so that all water moved through the PVP originates from the Poudre River upstream of the Glade Reservoir release point. This would allow FCWTF to receive raw water supply of appropriate quality for treatment when Horsetooth Reservoir and Glade Reservoir are not a suitable source for drinking water supply. The Corps must also consider the alternative of constructing a pre-treatment facility for releases from Glade Reservoir into the PVP to maintain the existing water quality parameters.

5.2.6 Analysis of TOC Levels in Horsetooth Reservoir

SDEIS Section 4.3.4.5, Effects on Water Treatment Plant Operations, Pages 4-117 and 4-118

Statement: "*The Horsetooth Reservoir water quality model (Hydros 2013) was used to evaluate changes in TOC concentrations for the Reclamation Action Option (ERO and Tetra Tech 2015). The model was used to estimate changes in TOC concentrations in the Soldier Canyon outflow, which would be the raw water supply to the Fort Collins and Tri-Districts WTPs.*"

"The model results for the Reclamation Action Option with and without a pipeline from Glade Reservoir to Horsetooth Reservoir are provided in Table 4-35.

"Table 4-35 shows that for the Soldier Canyon Outflow, which supplies Horsetooth Reservoir water to the Fort Collins and Tri Districts WTPs, average TOC concentrations are predicted to be higher under the Reclamation Action Option for the maximum pipeline volume. However, even for the highest average predicted TOC

concentration of 3.52 mg/L in the Soldier Canyon outflow, this would be only 3.5% higher than the baseline average TOC concentration of 3.40 mg/L."

Hydros Consulting, dated June 4, 2013, "Transmittal of Horsetooth Reservoir Model Simulation Results for NISP

Statement: "*The Horsetooth Reservoir model is a dynamic, two-dimensional hydrodynamic and water-quality model developed in the CE-QUAL-W2 (version 3.6) modeling framework. […] The model was calibrated and validated for the period January 2005 through September 2010.*

"*To allow for simulation of NISP scenarios which include pipeline inflow into Satanka Bay (located at the north end of the reservoir), the original Horsetooth model was modified slightly. Specifically, detail was added to the bathymetric representation of Satanka Bay to create a distinct model branch at this location to allow for inflows. []Bathymetric modifications were purposefully conducted to maintain the area-elevation-volume relationships of the original model. Simulation of observed conditions for the January 2005 through September 2010 period was performed with the modified model and compared to the same-period simulation from the original model. Differences in the water quality and hydrodynamics between the two runs were negligible.*

"*The simulation of observed conditions with the modified model (described above) for the full calibration and validation period (January 2005 through September 2010) served as the 'baseline' run against which all NISP scenario runs are compared in the results files provided to ERO Resources. All NISP scenarios for the Horsetooth Model runs were developed to simulate the same January 2005 through September 2010 time-period with varying inflows, outflows, and Satanka Bay pipeline water-quality assumptions. As such, for all runs, the same meteorology and Hansen Feeder Canal inflow concentrations were applied.*"

Comment: The conceptual approach described within the SDEIS regarding the quantification of the impact on TOC concentrations in Horsetooth Reservoir resulting from the transfer of water from Glade Reservoir is generally sound. However, a review of the modeling and resulting analysis suggest that the presented data and analysis are flawed and misleading, and inappropriately minimize the impact of Glade Reservoir water on expected TOC concentrations in Horsetooth Reservoir, which is a critical source of treated water for Fort Collins.

Per the documentation provided for the SDEIS and referenced as "Hydros, 2013" and "ERO and Tetra Tech 2015," a baseline CE-QUAL-W2 model ("baseline model") of Horsetooth Reservoir was developed and used to determine water quality impacts associated with the possible introduction of water from Glade Reservoir into Horsetooth Reservoir. The documentation of the model (from Hydros, 2013) suggests that the baseline model at times accurately reproduces measured TOC concentrations observed near the surface and reservoir bottom adjacent to the Solider Canyon Dam outlet. There are other times, however, where the baseline model continuously under predicted TOC concentrations at certain locations. Specifically, the baseline model under predicted observations made during the summers of 2005, 2006, and 2007 near the reservoir surface adjacent to Solider Canyon Dam. In 2005, the difference between modeled and observed TOC values appears to exceed 1 mg/L (or nearly 33% of the modeled value). Improved agreement is obtained near the bottom of Solider Canyon Dam (when compared to agreement at the surface). However, the baseline model also under predicts (by 0.5 mg/L or 16% of modeled value) TOC concentrations during the summer of 2005 and 2006. The amount of these under predictions is significant in terms of concentrations and percentages of modeled values.

The magnitude of the under predictions of TOC concentrations in Horsetooth Reservoir range from 0.5 mg/L to 1.0 mg/L. By comparison, the modeled average TOC concentration increase from the introduction of Glade Reservoir water into Horsetooth Reservoir is 3.5% or 0.12 mg/L. Because the modeled average TOC concentration increase is much smaller than the under prediction errors in modeled TOC concentrations, the modeled average TOC concentration increase is not believable or reliable.

In addition, average TOC concentrations should not be utilized to assess the impact of introducing Glade Reservoir water into Horsetooth Reservoir, as doing so masks any large increase event(s) that may occur in the specific water that is introduced into the City's system because such large increase event(s) are not identified in the average value. These large increase events are not evident in the results provided within the SDEIS, and would dictate any alternations needed to water treatment systems before Horsetooth Reservoir water that has been mixed with Glade Reservoir water could be utilized by Fort Collins.

Aside from concerns regarding the accuracy of the baseline model discussed above, Fort Collins has concerns regarding the modified model used to simulate Glade Reservoir inflows into Horsetooth Reservoir. For this discussion, this modified model is referred to as the "proposed-conditions model."

Per the documentation referenced above, the proposed-conditions model is similar to the baseline model discussed above except that it includes model cells representing Satanka Bay, and incorporates inflows from Glade Reservoir into Satanka Bay. Per the proposed-conditions model documentation, the impact of introducing Glade Reservoir water into Horsetooth Reservoir via Satanka Bay was determined by comparing computed Soldier Canyon outflow TOC concentrations from the proposed-conditions and baseline models, using the same January 2005 through September 2010 time period over which the baseline model was calibrated and validated.

This analysis approach is flawed and misleading. It is inappropriate to model the impacts of periodically introducing Glade Reservoir water into Horsetooth Reservoir without also altering the modeled inflows and outflows of water in Horsetooth Reservoir that are expected under Alternative 2, as described in the SDEIS. The results of the comparison of the baseline and proposed-conditions models presented in the SDEIS were generated without reducing the inflows and outflows in Horsetooth Reservoir as expected, but rather, with the exact inflows and outflows observed from 2005 to 2010. As the proposed-conditions model is not fully simulating the conditions to be expected under Alternative 2, the proposed-conditions model results cannot be utilized to assess TOC concentrations to be expected under Alternative 2. The SDEIS does not adequately present results showing how Horsetooth Reservoir TOC concentrations would differ as a result of Alternative 2.

The modeling effort must be revised, as discussed above, to provide sufficient confidence as to the accuracy of the predicted TOC concentrations in Horsetooth Reservoir under the District's preferred alternative (Alternative 2) where water is delivered from Glade Reservoir into Horsetooth Reservoir. Specifically, the under predictions errors in the baseline model must be addressed; average TOC concentrations alone must not be used to evaluate impacts, and instead, event TOC

increases must be considered in evaluating impacts; and the proposed-conditions model must incorporate the modeled inflows and outflows of water in Horsetooth Reservoir that are expected under Alternative 2.

5.3 COMMENTS REGARDING IMPACTS TO THE POUDRE RIVER AND WASTEWATER DISCHARGERS

5.3.1 Augmentation Program and Wastewater Discharges

SDEIS Section 2.5.6, Flow Augmentation

Statement: "*The District proposes to include a flow augmentation program to improve Poudre River streamflows, primarily during winter months when flows are low and NISP would generally not be diverting, in Alternative 2 (both the Reclamation Action Option and the No Reclamation Action Option). […]A method of exchange to return the water to Glade Reservoir would be determined between the SDEIS and FEIS.*"

Comment: Diversions of water under NISP will decrease flows in the Poudre River downstream of the Poudre Valley Canal headgate, including at the permitted points of discharge for the Fort Collins Mulberry WRF and the Drake WRF. The SDEIS offers augmentation of flow just below the Larimer & Weld Canal headgate in cool months (1 November – 30 April) and in September as a means of offsetting decreased flows. Augmentation would extend downstream to the headgate of the Timnath Inlet, including past the location of the Mulberry WRF point of discharge. While the augmentation amount (to maintain a minimum of 10 cfs) is specified for the augmentation point just below the Larimer & Weld Canal, the expected augmentation flows reaching the downstream point of discharge for the Mulberry WRF are not specified, and may be lower than current flows, which would cause increasingly stringent effluent limits for Mulberry WRF, with attendant compliance costs. In addition, termination of augmentation at the Timnath Inlet headgate, which is upstream of the Drake WRF, will reduce the amount of dilution flow available at the Drake WRF. The augmentation is not secure for all months or for dry years and does not have a defined beneficial effect downstream at the discharge points for the wastewater treatment facilities of Fort Collins.

If the Corps approves NISP, it must require as a permit condition a requirement that Northern ensures that river flows immediately above the permitted point of discharge for the Mulberry WRF do not drop below 10 cfs, as measured by a continuous data logger at that location, and ensures that river flows immediately above the permitted point of discharge for the Drake WRF do not drop below 2 cfs, as measured by a continuous data logger at that location.

5.3.2 Use of Cottonwood Trees to Reduce Increase in Water Temperatures

SDEIS Appendix F, Section: 4.3.2, Channel and Habitat Improvements

Statement: "*Channel improvements in this reach would seek to narrow and deepen the current channel to be more consistent with current and future low-flow conditions and increase riparian vegetation, including larger plains cottonwoods that would shade the river channel. The effectiveness of these proposed improvements to cool water temperature would be verified during the detailed water quality modeling."*

Comment: The reach of the Poudre River between the Poudre Valley Canal and the Hansen Supply Canal inflow is identified for mitigation through physical habitat improvement. Temperature, which

is regulated by the State for water quality protection, is one of the objectives for mitigation. As discussed above, water temperature in this cool water reach is expected to increase due to reduced flows, although the extent of temperature changes has not been analyzed by the Corps. The stated mechanism for mitigation of temperature in this cool water reach is the creation of new riparian shading.

There are flaws with this approach. First, this reach of the river is above the natural extent of plains cottonwoods which decrease in frequency as one moves upstream through the Fort Collins reach. Upstream of Fort Collins, the forests are dominated by narrowleaf cottonwood. Second, if part of the mitigation approach is to deepen the current channel, the bank topography will need to be adjusted to maintain river-floodplain connectivity. Without a link between the channel and the floodplain, periodic peak flows cannot support the establishment and survival of cottonwoods. Last, while shading is an important component of maintaining cooler temperatures, there will be a lag time (on the scale of multiple decades) before the trees provide this function. So, at minimum, in the interim, the Corps must require another plan to improve water temperatures. Further, without an assessment of the degree to which water temperature would change, there is no basis for assessing how adequate cottonwood shading would be in mitigating the impact.

The proposal to grow trees and then study the effectiveness through water monitoring *after* permitting represents a flaw prevalent throughout the SDEIS, i.e., inappropriately deferring analysis to a much later date when meaningful consideration should take place now. *See Kern*, 284 F.3d at 1075. NEPA prohibits "postpone[ing] analysis of an environmental consequence to the last possible moment." *Pacific Rivers Council*, 668 F.3d at 623. Further, the proposal to grow trees, without any analysis of the effectiveness of that measure, falls far short of NEPA's requirement that mitigation measures must be "reasonably complete." *See Robertson*, 490 U.S. at 352. It also fails to meet the requirements to avoid violation or exacerbation of water quality standards. *See* 40 C.F.R. § 230.10(b)(1).

The Corps must require a more rigorous and realistic program to reduce increased water temperatures resulting from NISP.

5.3.3 Trichloroethylene Plume at Glade Reservoir Forebay

SDEIS Appendix F, Section 3.4.1, Trichloroethylene Plume at Glade Reservoir Forebay

Statement: *"Trichloroethylene contaminated ground water is present beneath the northwest corner of the proposed forebay …The Corps and Northern Water would develop an agreement prior to construction of the forebay that determines the respective responsibilities of the Corps and Northern Water for implementing these mitigation measures."*

Comment: Since 2008, significant progress has been made in remediating the TCE-contaminated groundwater plume at Missile Site 13. Efforts include installation of six additional monitoring wells, installation of 54 injection wells, subsequent oxidative treatments, and testing groundwater samples for the chemicals of concern. The Corps and its consultant, Tidewater, Inc., are reporting success with oxidative treatments in reducing contaminant levels in the plume (Corps 2014_a).

If the Corps approves NISP, it must require as conditions of a permit a definite obligation and clear definition of respective responsibilities of the Corps and Northern to the continue remediation efforts at Site 13 until repeat testing of the monitoring wells shows that the chemicals of concern in groundwater do not exceed the federal maximum contaminant level.

[Remainder of Page Left Blank Intentionally]

SECTION 6: OPERATIONAL COMMENTS

The SDEIS's description of Alternative 2 includes a proposed flow augmentation program ("Augmentation Program") and certain descriptions of other operations, such as deliveries to NISP Participants. However, the Augmentation Program is flawed, includes incorrect assumptions, and raises significant concerns regarding its operations that preclude the ability to rely on the use of the Augmentation Program as minimization or mitigation. The SDEIS also lacks needed analysis and specificity on various aspects of the proposed operations regarding Alternative 2.

6.1 INCLUSION OF THE AUGMENTATION PROGRAM IN ALTERNATIVE 2 ONLY

SDEIS Section 2.5.1, Introduction/Abstract

Statement: "*Augmenting flows in the Poudre River by releases from a designated 3,600-AF release pool in Glade Reservoir with a target of maintaining a 10-cfs flow below the Larimer-Weld Canal headgate in November through April and September 1 through September 30.*"

SDEIS Section 2.5.6, Flow Augmentation

Statement: "*The District proposes to include a flow augmentation program to improve Poudre River streamflows, primarily during winter months when flows are low and NISP would generally not be diverting, in Alternative 2 (both the Reclamation Action Option and the No Reclamation Action Option).*"

SDEIS Section 2.2.7.4, Winter Flow Augmentation in Alternatives 3 and 4

Statement: "*Infrastructure associated with a Reclamation Action Option was eliminated for Alternatives 3 and 4. There would be no pipeline to deliver water from Cactus Hill Reservoir to an upstream location near the diversion for Greeley's Bellvue Filter Plant or the Hansen Supply Canal outlet. Therefore, Alternatives 3 and 4 would not include a flow augmentation program analogous to the proposed for Alternative 2…"*

SDEIS Appendix F, Section 3.2.4, Low Flow Augmentation Release (FW-04)

Statement: "*To further improve the cold water fishery on the Poudre River from the canyon mouth through Fort Collins, Northern Water would integrate a flow augmentation program that would release water from Glade Reservoir to improve Poudre River streamflow from the canyon mouth through Fort Collins.*"

Comment: Alternative 2 (the District's preferred alternative) includes the Augmentation Program, which includes fall and winter releases from Glade Reservoir. No alternative other than Alternative 2 includes proposals analogous or similar to the Augmentation Program. The alternatives other than Alternative 2 thus lack the proposed avoidance and minimization enjoyed by Alternative 2. The SDEIS contains no analysis to explain why the other alternatives cannot contain proposals analogous or similar to the Augmentation Program. When impacts among alternatives are compared in the SDEIS, Alternative 2 consequently shows fewer negative impacts than other alternatives. This skews the analysis of impacts in favor of Alternative 2. Due to the selective inclusion of the Augmentation Program in Alternative 2, the SDEIS thus fails to properly analyze the various alternatives. In violation of NEPA and the CWA, the Corps has not "objectively evaluate[d] [the] reasonable alternatives" to the proposed action. 40 C.F.R. § 1502.14(a).

The SDEIS justifies the omission of an Augmentation Program for Alternatives 3 and 4 by pointing to the lack of a pipeline between the proposed Cactus Hill Reservoir and the Poudre River.

The SDEIS is unclear as to why such a pipeline could not be constructed to allow augmentation releases. Moreover, the Alternatives 3 and 4 could be formulated to include a Reclamation Action Option, which would then necessitate inclusion of a pipeline between Cactus Hill Reservoir and the Poudre River. As further explained in the comment on SDEIS Section 2.2.7.3 below, including a Reclamation Action Option as part of Alternatives 3 and 4 is reasonable considering the large amount of infrastructure required to deliver water from Cactus Hill Reservoir to Participants under a No Reclamation Action Option. Were a pipeline constructed between Cactus Hill Reservoir and the Poudre River pursuant to a Reclamation Action Option, augmentation releases could be provided by the alternative. To the extent that the Augmentation Program is avoidance and minimization, such proposals are necessary.

The Corps inclusion of the Augmentation Program in Alternative 2 only is arbitrary and demands further explanation. To comply with NEPA's requirement that it "rigorously explore and objectively" evaluate all alternatives, the Corps must assess Alternatives 3 and 4 with proposals analogous or similar to the Augmentation Program. *See* 40 C.F.R. § 1502.14(a).

6.2 INCLUSION OF RECLAMATION OPTION IN ALTERNATIVE 2 ONLY

SDEIS Section 2.2.7.3, Reclamation Action Option in Alternatives 3 and 4

Statement: "*The Corps determined delivery of water by exchange, conveyance and/or storage using C-BT Project infrastructure was not practicable due to the location of the Cactus Hill Reservoir in Alternatives 3 and 4. […] The Corps therefore eliminated the Reclamation Action Option for Alternatives 3 and 4 from detailed analysis in the SDEIS.*"

Comment: The SDEIS eliminates a Reclamation Action Option from Alternatives 3 and 4 citing the difficulties in conveying water from Cactus Hill Reservoir at a distance of 30 miles back to Poudre River. No other justification for eliminating a Reclamation Action Option from Alternatives 3 and 4 is provided. In eliminating the Reclamation Action Option from Alternatives 3 and 4, the SDEIS does not provide a proper comparison of the two action alternatives with the proposed action (Alternative 2), particularly on the basis of project cost.

Despite dismissing the Reclamation Action Option out of concerns with pipeline distance and pumping inputs, Alternatives 3 and 4 propose pipeline routes in excess of 30 miles with multiple pumping stations to deliver water from Cactus Hill Reservoir to Participants, at a cost of $144,536,000 (SDEIS Table 2-12). As proposed in the comment above regarding SDEIS Appendix F, Section 3.2.4, constructing a pipeline between Cactus Hill Reservoir and the Poudre River would allow for releases from Cactus Hill Reservoir to be made back to the Poudre River, and would make practicable the Reclamation Action Option as well as the proposed Augmentation Program. Extending such a pipeline to Horsetooth Reservoir, similar to that proposed for Alternative 2, may be necessary to fully execute the Reclamation Action Option. Such a pipeline would raise water quality issues as discussed elsewhere in Fort Collins' comments. A Reclamation Action Option made available by constructing a pipeline between Cactus Hill Reservoir and the Poudre River would eliminate the need to construct the expansive distribution network proposed in Alternatives 3 and 4. As a result, it is possible that the Reclamation Action Option for Alternatives 3 and 4 would not result in a substantial capital cost relative to the total capital cost for the alternatives.

However, in order to properly compare costs between the Reclamation Action and No Reclamation Action Options for Alternatives 3 and 4, the Corps should disclose a comparative cost analysis.

As stated above, to comply with NEPA's requirement that it "rigorously explore and objectively" evaluate all alternatives, the Corps must assess Alternatives 3 and 4 with a Reclamation Action Option. The Corps must also conduct comparative cost analyses, as discussed above.

6.3 AUGMENTATION PROGRAM CONCERNS

SDEIS Section 2.5.6, Flow Augmentation

Statement: "*Water that is reduced to storage becomes the personal property of the District. The District intends to exercise its statutory right to release stored water for delivery downstream for a decreed beneficial use and to inform the state and division engineers that the water released from storage is to be shepherded downstream to a specified diversion point without being diverted by others, as required by Colorado law (Colorado Revised Status [CRS] 37-87-103)[…] For NEPA analyses, it was assumed that the flows would be re-diverted at the Timnath Reservoir (also known as Cache la Poudre Reservoir) inlet canal headgate […] A method of exchange to return the water to Glade Reservoir would be determined between the SDEIS and FEIS.*"

SDEIS Section 2.5.9.1, Sources of Water for Initial Fill of NISP Storage Reservoirs

Statement: "*Until operations of the SPWCP commenced, Glade Reservoir would be wholly dependent on the Grey Mountain water right.*"

SDEIS Appendix F, Section 3.2.4, Low Flow Augmentation Release (FW-04)

Statement: "*The following provides information on the low flow augmentation release program: … the average annual release to maintain this flow is not increased, and the other aspects of the program are not materially different from those proposed herein.*"

Comment: The Augmentation Program lacks the certainty needed to ensure that it will operate as claimed to achieve its goals, and that the intended avoidance and minimization will be accomplished. As discussed below, this lack of certainty creates the likelihood of legal challenges to the Augmentation Program, and/or a determination by the Colorado State and Division Engineers that Augmentation Program cannot be administered and/or is not lawful. Because of these uncertainties, the Corps cannot rely on the Augmentation Program as currently proposed to make the required findings under Section 404(b)(1) Guidelines. Problems with the Augmentation Program would cause Fort Collins to bear more impacts than determined by the Corps in the SDEIS, with limited recourse to resolve such issues. The following are specific issues regarding the Augmentation Program and proposals to address such issues.

6.3.1 Use of Water that Has Been Diverted to Storage

Comment: The SDEIS statements that "[w]ater that is reduced to storage becomes the personal property of the District" and that "[w]ater which is stored in Glade Reservoir would become the property of Northern Water" are not correct under Colorado law, as the Colorado Supreme Court explained in *Bijou Irrigation Dist. v. Empire Club*, 804 P.2d 175, 184 & n.15 (Colo. 1991). The Court explained that "[a]lthough we have stated that water once diverted becomes the personal

property of the appropriator … this somewhat overstates the scope of the right." *Id*. (citation omitted). "[W]ater diverted by exercise of a storage right must ultimately be applied to the beneficial use for which the water was appropriated." *Id*. at 184 n.15 (citations omitted).

Under Colorado law, the District only has the right to use the water it has diverted, into storage or otherwise, pursuant to the terms and conditions of its water rights. *Id*. *See also, e.g., Santa Fe Trail Ranches Prop. Owners Ass'n v. Simpson*, 990 P.2d 46, 54 (Colo. 1999). This legal error renders invalid the SDEIS analysis of the Augmentation Program, as discussed further below.

If NISP is approved, the Corps must require as a condition of the permit that all water rights proposed for use in the Augmentation Program be confirmed to be lawfully available for such proposed use pursuant to the terms and conditions of the subject water right decrees, Colorado law, and current administrative practices of the Colorado State and Division Engineers.

6.3.2 Proposed Use of the Grey Mountain Water Right for Replacement and/or Recreational Uses

Comment: The District proposes in the SDEIS to use water attributable to its Grey Mountain Water Right in the Augmentation Program by delivering water attributable to that water right to the Poudre River and re-diverting the water at the Timnath Inlet Canal headgate for further use. The Grey Mountain Water Right was originally confirmed as a conditional water right in the decree entered in Case No. 1980CW355, District Court, Water Division 1, with the decreed uses being irrigation, municipal, domestic, industrial, and production of electrical power and energy. *See* 80CW335 Decree at ¶3.I.

A decree continuing the conditional Grey Mountain Water Right was entered in Case No. 1989CW122, District Court, Water Division 1 (which had been consolidated with Case Nos. 1985CW206, 1985CW207, 1985CW208, 1985CW209, and 1985CW210). 85CW206 et al. Decree at ¶4 (identifying Case No. 1989CW122 and the Grey Mountain Water Right) and ¶18 (diligence finding). The decreed uses in that case are the same as stated in Case No. 1980CW355. *Id*. at ¶4.C. A decree continuing the conditional Grey Mountain Water Right was entered in Case No. 2001CW197, District Court, Water Division 1. The decreed uses in that case are the same as stated in Case No. 1980CW355 and Case No. 1989CW122. 01CW197 Decree at ¶7.F.

The Grey Mountain Water Right was changed in Case No. 2003CW405, District Court, Water Division 1, to add Glade Reservoir as an alternate place of storage and to add three alternate points of diversion; no changes to the decreed uses of the Grey Mountain Water Right were approved in that case. 03CW405 Decree at ¶¶4, 7.A. The decreed uses in that case are the same as stated in Case No. 1980CW355, Case No. 1989CW122, and Case No. 2001CW197. 03CW405 Decree at ¶6.b.e. There have been no other changes of the Grey Mountain Water Right. The Grey Mountain Water Right has not been decreed for reuse or successive use.

The most recent decree continuing the conditional Grey Mountain Water Right was entered in Case No. 2011CW242, District Court, Water Division 1, and identifies the decreed uses of the water right as irrigation, municipal, domestic, replacement, recreation, industrial, and production of

electrical power and energy. 11CW242 Decree at ¶7.1.7. In that case as in previous diligence cases (Case No. 89CW122 and Case No. 2001CW197), the District only invoked the Court's jurisdiction to seek findings of reasonable diligence and to continue the conditional Grey Mountain Water Right for another diligence period. *See* C.R.S. §37-92-301(4)(a)(I); *Dallas Creek Water Co. v. Huey*, 933 P.2d 27, 36-37 (Colo. 1997). The Court had no jurisdiction in Case No. 2011CW242to change the uses of the Grey Mountain Water Right, including no jurisdiction to add new uses to the Grey Mountain Water Right. *See* C.R.S. 37-92-302; *Matter of Application for Water Rights v. Columbine Assoc.*, 993 P.2d 483, 489 (Colo. 2000).

The only currently decreed uses of the Grey Mountain Water Right that could potentially relate to the Augmentation Program are replacement and recreation. However, as discussed above, any replacement or recreation use of the Grey Mountain Water Right is not a lawful use of that water right because the Court had no jurisdiction to add such new uses. Such jurisdictional defects can be raised at any time. *E.g., id*. at 488. To the extent that the use of the Grey Mountain Water Right's proposed use in the Augmentation Program is replacement or recreation use, such proposed use may not be administered by the Colorado State and Division Engineers and is vulnerable to a legal challenge, unless the water right is changed in proceedings before the District Court, Water Division 1. C.R.S. §37-92-305(3)(a).

If the Corps approves NISP, it must require as a condition of the permit that the Grey Mountain Water Right may not be included in the Augmentation Program unless and until the District receives judicial approval for a change of use of the Grey Mountain Water Right pursuant to C.R.S. §37-92-305(3)(a), or temporary approval from the State Engineer for a change of use of the Grey Mountain Water Right pursuant to C.R.S. §37-92-308 or successor statutes, such that the Grey Mountain Water Right can be used in the Augmentation Program. Provided that such a proposed change of water right were shown to not adversely affect Fort Collins' water rights, Fort Collins would likely not oppose such a change of the Grey Mountain Water Right. If the Corps must rely on the Augmentation Program to make its LEDPA and other findings, then no action under a permit shall be allowed unless and until the District receives such approvals.

The District could also include other water rights in the Augmentation Program that are currently legally available for the appropriate uses. The District's water rights decreed in Case No. 1992CW130, District Court, Water Division 1, may be such water rights. However, to the extent that such water rights are not or will not be available when needed under the Augmentation Program, any approval of NISP must require the District to acquire ownership of, or the right to use other water rights and to dedicate them to the Augmentation Program. For instance, various senior water rights have been previously changed for various new uses and decreed for storage in Glade Reservoir, which may be a source of water rights for the Augmentation Program. Other water rights are used to import water into the Poudre River Basin, which may be a source of water rights for the Augmentation Program. Further, water diverted during "free river" conditions, when there is no downstream call, could be attributed to a junior and undecreed "free river" water right (and not the Grey Mountain Water Right) and may be available for use in the Augmentation Program.

The above concerns regarding the uses of the Grey Mountain Water Right would also be addressed if the District were simply relinquishing water from storage to the stream or if the water

were being delivered in the Poudre River stream channel for re-diversion (directly or by exchange) for a decreed beneficial use downstream, both assuming that the water so relinquished would reach the desired location(s), as discussed further below.

Whichever other water rights are used, or however the Augmentation Program may be re-formulated, any approval of NISP must require the District to identify and substantiate the legal and physical availability of water under such water rights for use in the Augmentation Program to guarantee that the proposed Augmentation Program will be achievable.

6.3.3 Proposed Re-Use and Successive Use of Water Attributable to the Grey Mountain Water Right

Comment: Even if the Grey Mountain Water Right can be used for replacement or recreation use in the Augmentation Program, its proposed reuse and successive use, as described in the SDEIS, is in violation of the decrees confirming the water right. Water attributable to a tributary water right, like the Grey Mountain Water Right, that has not been delivered into an unconnected stream system can only be used once, unless it is decreed for reuse and successive use. *WSSC v. Curtis*, 733 P.2d 680 (Colo. 1987). *See also Denver v. Fulton Irrigating Ditch Co.*, 506 P.2d 144, 146-47, 179 Colo. 47, 52 (1972) (defining reuse and successive use). If not decreed for reuse or successive use and not delivered into an unconnected stream system, the return flows from the first use of the water can only be re-diverted under a separate water right. *Santa Fe Trail*, 990 P.2d at 54.

The Grey Mountain Water Right is not decreed for reuse or successive use and water attributable to the water right will only be used within the South Platte River basin, which includes the Poudre River basin. Therefore, once water attributable to the Grey Mountain Water Right is used the first time, such as delivering it to the Poudre River for replacement or recreation use in the Augmentation Program, the District has no right to reuse and re-divert it under the Grey Mountain Water Right. The District can instead only re-divert the water under a separate water right. However, no such other water right is identified in the SDEIS.

If the Corps approves NISP, it must require as a permit condition that water attributable to the Grey Mountain Water Right may not be reused or successively used under the Augmentation Program, or otherwise, unless and until the District receives judicial approval for a change of use of the Grey Mountain Water Right pursuant to C.R.S. §37-92-305(3)(a), or temporary approval from the State Engineer for a change of use of the Grey Mountain Water Right pursuant to C.R.S. §37-92-308 or successor statutes, such that water attributable to the Grey Mountain Water Right can be reused and successively used. Provided that such a proposed change of water right were shown to not adversely affect Fort Collins' water rights, Fort Collins would likely not oppose such a change of the Grey Mountain Water Right.

To the extent that the District intends to re-divert water used in the Augmentation Program, the District could include other water rights in the Augmentation Program that are legally available for reuse and successive use. The District's water rights decreed in Case No. 1992CW130, District Court, Water Division 1, may be such water rights. However, to the extent that such water rights are not or will not be available when needed under the Augmentation Program, any approval of NISP

must require the District to acquire ownership of, or the right to use other water rights and to dedicate them to the Augmentation Program. For instance, various senior water rights have been previously changed for reuse. Other water rights are used to import water into the Poudre River Basin, which may be a source of reusable water. Further, water diverted during "free river" conditions when there is no downstream call could be attributed to a junior "free river" water right (and not the Grey Mountain Water Right) and may be available for reuse and successive use.

Whichever other water rights are used or however the Augmentation Program may be re-formulated, the Corps must require the District to identify and substantiate the legal and physical availability of water under such water rights for reuse and successive use in the Augmentation Program to guarantee that the proposed Augmentation Program will be achievable.

6.3.4 No Analysis of Substitutions and Exchanges on Augmentation Program Flows

Comment: The SDEIS statements that CRS §37-87-103 entitles the District to use the natural stream for the delivery of water without others using such water are incorrect. Other water users may divert such water provided that they deliver a substitute supply above the point of re-diversion. *E.g.,* C.R.S. §37-92-305(5); *Empire Lodge Homeowners' Ass'n v. Moyer*, 39 P.3d 1139, 1153-55 (Colo. 2001). As described in the SDEIS, the District currently lacks a legal mechanism to ensure that water proposed to be delivered from Glade Reservoir to the Timnath Inlet Canal headgate is protected from intervening diversions, substitutions, and exchanges. Section 3.2.5 of Appendix F of the SDEIS confirms the District's current inability to protect such flows. The SDEIS contains no analysis of how the District will ensure that such deliveries of water will actually remain in the Poudre River to avoid and minimize the reduction of flows.

To comply with NEPA and the CWA, the Corps must require an analysis be performed to demonstrate that deliveries of water under the Augmentation Program will actually remain in the Poudre River to avoid and minimize the reduction of flows. The Corps must require additional measuring stations to establish that deliveries of water under the Augmentation Program are not diverted and substituted. To the extent that the Augmentation Program constitutes mitigation, under the Section 404(b)(1) Guidelines, the Corps' mitigation must "have been demonstrated to be effective in circumstances similar to those under consideration." 40 C.F.R. § 230.75(d). *See Kentucky Riverkeeper v. Rowlette*, 714 F.3d 402, 412 (6th Cir. 2013) (The Corps' "mere listing of mitigation measures and processes, without any analysis, cannot support a cumulative impacts determination."). Any approval of NISP must require a high level of certainty that the water delivered to the stream under the Augmentation Program will actually reach its intended destination so as to guarantee that the proposed Augmentation Program will be achievable. In violation of NEPA and the CWA, the SDEIS fails to demonstrate that the Augmentation Program would be viable and effective to meet its goals. *See Robertson*, 490 U.S. at 352.

6.3.5 No Analysis of the Ability of the District to Deliver Flows in the Augmentation Program Past All Intervening Headgates

Comment: The SDEIS indicates that water in the Augmentation Program would be delivered to the Poudre River "via a pipeline to the river upstream of the Larimer County Canal headgate." This

would mean that the Colorado State and Division Engineers would need to shepherd such water past the following diversion structures to reach the Timnath Inlet Canal headgate: (1) the diversion structures for the Larimer County Canal headgate; (2) the diversion structures for Watson Lake; (3) the diversion structures for the Jackson Ditch (a.k.a Dry Creek Ditch); (4) the shared the diversion structures for the New Mercer Ditch, Larimer County No. 2 Ditch, Little Cache la Poudre Ditch, and Taylor and Gill Ditch; (5) the diversion structures for the Arthur Ditch; (6) the diversion structures for the Larimer and Weld Canal; and (7) the diversion structures for the Lake Canal. The majority of these diversion structures lack necessary measurement structures to ensure that water can be shepherded past them, especially during periods of low flow or when the ditch is diverting the entire flow of the river.

While the NISP Proposed Conceptual Mitigation Plan (Appendix F, Section 4.4.3) provides for multi-objective retrofits for three of the above diversion structures (the Watson Lake, Terry Lake, and Larimer and Weld diversions) that may allow for streamflow monitoring, other diversions listed above will not have associated streamflow monitoring, and thus cannot be ensured to bypass flows attributable to the Augmentation Program. The SDEIS contains no analysis of how the District will ensure that such deliveries of water in the Poudre River will actually reach the desired downstream location.

To comply with NEPA and the CWA, an analysis must be performed to establish that deliveries of water under the Augmentation Program will be delivered past all intervening headgates so as to guarantee that the proposed Augmentation Program will be achievable.

6.3.6 Augmentation Program During Times of Drought

Comment: The SDEIS indicates that releases of water under the Augmentation Program may not occur under extreme drought conditions when Glade Reservoir storage contents are less than 30% of capacity. According to Figure 3.15 of the SDEIS Operations Plan Report, Glade Reservoir would drop below 30 percent of capacity (or 51,000 acre-feet of the proposed 170,000 acre-feet) in the late 1950s, the mid-1990s and the mid-2000s conditions– indicating that the Augmentation Program may not occur three times during the study period of 1950 through 2005. However, a comparison of pre- and post-augmentation flows (assessed through PPP and final flow data provided by the Corps) indicates the augmentation flows occurred during these same years and were thus included in the impacts analysis, which therefore improved environmental outcomes. It is likely that such drought conditions will coincide with low flows in the Poudre River, including flows less than 10 cfs below the Larimer and Weld Canal headgate. However, by its own proposed terms and conditions the Augmentation Program would not operate when most needed. The failure of the Augmentation Program to address the effects of diversions to Glade Reservoir when the effects are being most intensely experienced undermines the purposes of the Augmentation Program. The impacts from the Augmentation Program must be specifically addressed.

The Corps must require that the Augmentation Program operate at all times, including during extreme drought years when augmentation flows are needed the most, in order to address impacts, as claimed.

6.3.7 No Analysis of Subsequent Exchanges Using Augmentation Program Flows

Comment: The SDEIS states that water released from Glade Reservoir for the Augmentation Program will be returned to Glade Reservoir, possibly through the use of exchanges. However, the actual method of exchange to return the water to Glade Reservoir is not specified in the SDEIS.

The SDEIS fails to explain how such exchanges would occur under the subject water right decrees. For example, the decree entered in Case No. 1992CW130, District Court, Water Division 1, approved certain conditional appropriative rights of exchange, with findings of diligence for those conditional exchanges having been entered in Case No. 2011CW241, District Court, Water Division 1. The sources of water for those exchanges are (1) water diverted under the SPWCP water rights confirmed in Case No. 1992CW130 and (2) water from other reusable sources, provided that such use is allowed by another decree and is agreed to by the sources' owners. As discussed above, water attributable to the Grey Mountain Water Right is not currently legally available for use as a source of water for these exchanges. The SDEIS contains no analysis of these aspects of these unspecified exchanges.

Exchanging augmentation releases back to Glade Reservoir has the potential to reduce Poudre River streamflows along the 12 mile reach through Fort Collins between the proposed augmentation release point and the Timnath Inlet Canal headgate, and may result in impacts to the Poudre River's aquatic environment, which are discussed elsewhere in these comments.

To comply with NEPA and the CWA, the SDEIS must clearly describe the method and frequency of which these exchanges will be conducted, and must consider and quantify the environmental impacts with associated streamflow depletions from all exchanges.

6.4 IMPACTS ON THE PVP

SDEIS Section 2.5.5.2.1, Deliveries to Participants / Reclamation Action Option

Statement: "*Fort-Collins-Loveland Water District (3,000 AFY) would use its own capacity in the existing Pleasant Valley Pipeline by direct connection from Glade Reservoir.*"

Comment: Alternative 2 (the District's preferred alternative) includes a direct connection between Glade Reservoir and the PVP. Fort Collins and the Tri-Districts (the East Larimer County Water District, the Fort-Collins-Loveland Water District, and the North Weld County Water District) share use of the PVP to deliver water to Fort Collins' and the Tri-Districts' respective water treatment facilities. As discussed in other sections of these comments, the water released from Glade Reservoir will be of a lower quality than other water that has historically been delivered through the PVP. As one example, water released from Glade Reservoir may have high levels of TOC. Releases high in TOC from Glade Reservoir to the PVP will degrade the quality of raw water to Fort Collins treatment plant and necessitate more intensive treatment, as discussed below.

Unless the quality of water released from Glade Reservoir and delivered to the PVP is acceptable to Fort Collins, Fort Collins may exercise its rights to withhold approval of such use of the PVP pursuant to Paragraph 3.a of the Allotment Contract with the Northern Colorado Water

Conservancy District, acting by and Through the Pleasant Valley Pipeline Water Activity Enterprise and the City of Fort Collins Water Utility Enterprise for Capacity in the Pleasant Valley Pipeline, dated February 28, 2003.

The measures and alternative analysis required in Section 5.2.5 of these comments apply here as well. The Corps must also analyze how Alternative 2 would work without this connection.

6.5 HOW DELIVERIES TO NISP PARTICIPANTS ARE TO BE MADE

SDEIS Section 2.5.5.2.1. Deliveries to Participants / Reclamation Action Option

Statement: "*Eaton, Severance, and Windsor (5,900 AFY) would be by direct pipeline connection from Glade Reservoir to the Soldier Canyon Filter Plant.*"

SDEIS Appendix F, Section 3.2.1, Avoid Munroe Canal Diversions (FW-01)

Statement: *"The original Draft EIS considered using the Munroe Canal for two operations associated with NISP. […] The exchange has been eliminated in the SDEIS analysis, and replaced with a new pipeline directly from Glade Reservoir to the Pleasant Valley Pipeline (for Fort Collins-Loveland Water District) and a new pipeline directly from Glade Reservoir to the Soldier Canyon Filter Plant (for Eaton, Severance and Windsor)."*

Comment: The SDEIS mentions that the NISP participants of Eaton, Severance, and Windsor would receive water via a direct connection between Glade Reservoir to Soldier Canyon Filter Plant. However, the Corps must provide additional information regarding the pipeline(s), including, but not limited to, its route(s), what land(s) would be disturbed by its construction and use, how the proposed pipeline(s) would be constructed and operated, the socioeconomic impacts of such pipeline(s), and whether environmentally sensitive or affected areas would be involved. To comply with NEPA and the CWA, the SDEIS must evaluate the impacts of any delivery pipeline(s). If the deliveries are proposed to be made through the PVP, Fort Collins' comments above regarding the PVP apply.

6.6 RESOURCES FOR SECTION 6

- Decrees, District Court, Water Division 1: Case No. 1980CW335; Consol. Case Nos. 1985CW206, 1985CW207, 1985CW208, 1985CW209, 1985CW210, 1989CW122; Case No. 2001CW197; Case No. 1992CW130; Case No. 2003CW405; Case No. 2011CW242.

[Remainder of Page Left Blank Intentionally]

SECTION 7: CHANNEL STRUCTURE, STORM WATER, FLOODPLAIN, AND HYDRAULIC COMMENTS

Fort Collins is located in the Poudre River basin, and thus, the Poudre River is the primary conduit for drainage, storm water, flood waters, and other flows. As discussed herein, NISP's alterations to, among other things, stream morphology and sediment transport, will adversely affect Fort Collins' use of the Poudre River for these services.

The City of Fort Collins' Strategic Plan recognizes the importance of the Poudre River to environmental health, community safety, recreation and economic health. Strategic Objective 4.1 call for Fort Collins to improve and protect wildlife habitat and the ecosystems of the Poudre River and other urban streams. This plan also recognizes that the Poudre River has multiple and, at times, competing demands from various users, while at the same time being a natural amenity and ecosystem to be carefully nurtured and maintained. The plan thus directs that, given multiple stresses on the ecology of the Poudre River, there will be a need for local and regional investments if river health is to be maintained and/or improved. The plan also identifies that a healthy Poudre River supports the economy of downtown Fort Collins.

The stream morphology and sediment transport analysis in the SDEIS contain some important analyses that were originally omitted from the DEIS. However, these analyses and the conclusions drawn from them are fundamentally flawed because the sediment transport modeling underpinning the new analyses is incorrect, as discussed below. Thus, without further and independent evaluation of hydraulic modeling by the Corps, the impacts of the proposed action cannot be determined.

In addition to errors in the modeling, the SDEIS fails to properly analyze likely extent of channel changes, sediment deposition, and other impacts to habitat quality that are not well supported by the analyses and evidence provided in the SDEIS. These fundamental flaws in the sediment transport analyses result in underestimation of NISP impacts to various river characteristics including channel capacity to convey floods, aesthetics, and physical habitat for aquatic life.

7.1 NO ANALYSIS OF COSTS AND FLOODING RISKS IN FORT COLLINS

SDEIS Section 3.4.2.4, Morphologic and Sediment Transport Conditions Upstream of I-25

Statement: "*Stream morphology in the upstream reaches from the canyon through Fort Collins to the vicinity of I-25 is flood-dominated morphology. […] Deposition and vegetation encroachment will continue in discrete areas – probably at a similar rate to the current unless some unpredicted intrinsic threshold is reached or some other change occurs such as an invasion of reed canary grass or a substantial increase in sediment supply from upstream sources.*"

Comment: The SDEIS fails to address how much additional sediment is expected to accumulate in the Fort Collins reach of the Poudre River following construction of NISP. This information is needed to assess the cost of damages and other impacts to Fort Collins on an annual basis to determine proper compensatory mitigation. Based on historic sediment removal projects in Fort Collins, the cost to remove sediment from the river can vary from $20 to $80 per ton depending on

location, hauling distance, equipment used, and type of material. These efforts also have environmental impacts that must be considered when evaluating the impacts of NISP.

The SDEIS geomorphic analysis fails to properly assess the potential for decreased flood conveyance capacity and increased flood depths associated with channel aggradation, narrowing, and vegetation encroachment within Fort Collins. This is a point that must be addressed with regard to public safety and potential costs to Fort Collins. Fort Collins has an interest in maintaining a healthy and functional river system which retains an open channel capable of transporting storm water and flood flows. The process of sediment deposition without the process of sediment flushing through scouring and erosion will lead to vegetation encroachment and subsequent channel constriction. These changes will significantly change the Poudre River's function as a conveyor of flood water and result in flow obstruction, increased flood stages and possibly greater flood damage in the future.

The SDEIS's characterization that the Poudre River transitions from a sediment "supply limited" to sediment "transport limited" system at its crossing of I-25 is a generalization that fails to address the impacts of NISP on specific reaches of the Poudre River throughout Fort Collins. More detailed analysis and mitigation actions for specific reaches within Fort Collins must be developed prior to approval of NISP. Reduction of runoff peak flows will likely increase sedimentation within Fort Collins, thereby exacerbating flooding risk.

Under NEPA and the CWA, the Corps must take a hard look at the additional sediment accumulation and associated impacts in the Fort Collins reach of the Poudre River that may be caused by the proposed action. It must also determine and document the mitigation measures that would adequately address those impacts. *See* 40 C.F.R. § 230.11. As stated above, unless these measures are properly identified and addressed, the Corps "has not met its legal obligation and any proposed mitigation measures dependent upon an incomplete environmental impact analysis necessarily fail . . . ." *Ohio Valley Envtl. Coalition*, 479 F.Supp.2d at 627.

7.2 LACK OF SUPPORT FOR CONCLUSIONS OF MINOR IMPACTS

SDEIS Section 4.4.3.1.1, Poudre River Flows and Flooding

Statement: "*Widespread 20% to 35% predicted reductions in flows around the 1% to 5% flow range may have an impact on channel forming discharges and channel morphology.*"

SDEIS Section 4.4.3.1.1, Poudre River Sediment Transport

Statement: "*Under Alternative 2, it is possible that the reduced incidence of flows around the current 1- and 2-year flood level would increase the likelihood that colonizing vegetation can become established before it is scoured out by subsequent high flows. Channel contraction can then be driven by vegetation in the absence of abundant sediment.*"

SDEIS Section 4.4.7.1, Impact Summary Poudre River, Table 4-53, Page 4-173

Statement: "*Effects of Alternative 2 on geomorphology and sediment transport may result in a detectable change that is considered to be minor in the reaches upstream of I-25. Downstream of I-25 Alternative 2 effects may result in a clear detectable change that is considered to be moderate.*"

Stream Morphology and Sediment Transport Cache La Poudre River Mainstem, Final Project Effects Report, Section 1.5.1, Trajectory Upstream of I-25, Page 1-8

Statement: "*Despite the relative stability of the existing condition, there is still a propensity to aggradation, constrained in the current condition by the limited availability of incoming sediment compared to the ability of the channel to transport it. Deposition and vegetation encroachment will continue in discrete areas – probably at a similar rate to the current…*"

Comment: The SDEIS generally underestimates the likelihood of sediment deposition, vegetation encroachment, channel shrinking, and lost flood conveyance through Fort Collins. On this issue, the SDEIS contains numerous examples of conclusions that run contrary to presented data and analyses with respect to the current trajectory and likely response of the river channel in Fort Collins. There also are numerous examples of the SDEIS contradicting itself. Under NEPA and the CWA, the Corps' explanation is not "satisfactory" if the "explanation for its decision . . . runs counter to the evidence before" it. *Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43 (1983).

As one example, the Stream Morphology and Sediment Transport Cache La Poudre River Mainstem, Final Project Effects Report, dated August 15, 2014 ("Effects Report"), at pages 1-7, states that "[u]pstream of I-25 the river channel is larger and steeper but there is also a strong aggradational tendency associated with reduced flows." Yet the Effects Report ultimately concludes that the river through Fort Collins will remain "supply limited" and unresponsive relative to downstream reaches because there is not enough sediment supply to cause any more than "minor" aggradation. In contrast, the Poudre River downstream of I-25 is deemed "transport limited" and more at risk, owing to its relatively high sediment supply (e.g., Table 4-53, p. 4-172 of main SDEIS document).

As another example, the SDEIS identifies widespread 20% to 35% reductions in flows, as quoted above, early in Section 4 of the SDEIS. SDEIS, Section 4.4.3.1.1 at 4-157. However, by the end of Section 4 in the SDEIS, this impact is marginalized on the basis of a supply limited condition upstream of I-25. A supply limited condition does exist upstream of I-25 that does not preclude episodes of high sediment loading, such as after a wildfire or slope instability somewhere in the watershed. Nevertheless, the reduction of high flows by NISP will clearly impact the ability of the channel to flush excess sediment through Fort Collins when these events do occur. More specifically, the SDEIS concluded that "[f]or the 26-year period of record, 23 flushing events under Current Conditions lasting for 325 days in total would become 16 flushing events under Alternative 2 lasting for 222 days in total." SDEIS, Section 4.4.3, page 4-158. This reduced flushing potential under NISP will impact channel conditions, particularly after high sediment producing events, resulting in changes in channel morphology. And yet the discussion in this section concludes with a statement that the effects of Alternative 2 on geomorphology and sediment transport is "minor in the reaches upstream of I-25." (Table 4-53, page 4-173).

As one further example, the SDEIS identifies the possibility that reduced flows will increase vegetation and channel contraction, as quote above, early in Section 4. SDEIS, Section 4.4.3.1.2 at 4-160. However, by the end of Section 4 this possible impact is largely overlooked given the conclusion of "minor" impacts (Table 4-53, page 4-173). With the substantially reduced flow

conditions under NISP, vegetation encroachment will occur on sand and gravel bars that were previously more frequently inundated. The supply limited condition upstream of I-25 may reduce the potential of fluvial sediment deposits on exposed bars that would facilitate vegetation encroachment, however, some sediments will still accumulate (including Aeolian sediment) and vegetation encroachment will occur in the Fort Collins reach under NISP.

The above conclusions from the SDEIS are not supported by evidence and are in conflict with general principles of stream morphology. First, aggradation or deposition of sand and fine sediment depends on the supply of sediment relative to the capacity of the river to transport the supplied sediment, not just the supply of sediment. If capacity to move sediment is sufficiently reduced, a "supply limited" channel will shift to transport limitation and sediment accumulation will accelerate. Second, the vast majority of the sand and coarse sediment load that is supplied to the Timnath and Windsor reaches of the Poudre first flows through Fort Collins. Third, Alternative 2 would decrease the sediment transport capacity of the river through Fort Collins to a level below that currently found in the Timnath reach that extends four miles downstream of I-25. The tables below summarize modeling results compiled from the Effects Report to compare current conditions in Timnath and Windsor with Alternative 2 conditions in Fort Collins.

Excerpt from Table 3.2 Exceedance Probability Discharge, Alternative 2 vs Current Conditions (Effects Report p 3-5):

Location	Node	CTP Scenario	Exceedance	Flow (cfs)
Fort Collins	17	Alt 2	1% flow	2023
Fort Collins	20	Alt 2	1% flow	2037
Fort Collins	23	Alt 2	1% flow	2089
Timnath	32	Current	1% flow	2200
Timnath	34	Current	1% flow	2297
Windsor	35	Current	1% flow	2358
Fort Collins	17	Alt 2	2% flow	1348
Fort Collins	20	Alt 2	2% flow	1316
Fort Collins	23	Alt 2	2% flow	1285
Timnath	32	Current	2% flow	1603
Timnath	34	Current	2% flow	1674
Windsor	35	Current	2% flow	1711

Excerpt from Table 3.11 Reach Averaged Sediment Transport Potential using SIAM – Alternative 2 vs Current Conditions (Effects Report p 3-32):

Difference between Current average transport of sand and gravel in Fort Collins as compared to Current in Timnath	15%
Difference between Current average sand transport in Fort Collins as compared to Current in Timnath	18%
Difference between Alt 2 average transport of sand and gravel in Fort Collins as compared to Current in Timnath	-10%
Difference between Alt 2 average sand transport in Fort Collins as compared to Current in Timnath	-12%

Note: Data in the table above compares 6 out of 7 SIAM reaches in Fort Collins (omitted outlier reach FC 3) with Timnath A reach which extends 4 miles below I-25.

These SIAM modeling results indicate that Alternative 2 would reduce sediment transport capacity of the Poudre River in Fort Collins to levels below the transport capacity currently witnessed in Timnath. The Poudre River in Timnath immediately below I-25 is described in the Stream Morphology and Sediment Transport Cache la Poudre River Mainstem Baseline Report, dated May 2013 ("Baseline Report"), as being dominated by fine sediment deposition which reinforces vegetation encroachment and loss of channel flood conveyance. (Note that the SIAM analysis still uses the Meyer-Peter Mueller transport equation which underestimates differences in sediment transport capacity for river bed particles near the threshold of motion). Ultimately, the SDEIS presents no meaningful evidence to support the conjecture that the Poudre River in Fort Collins will sustain only "minor" aggradation, and remain supply limited given reductions of sediment transport capacity of approximately 30-35% in some reaches (Table 7.12 on p. 7-33 in the Effects Report). Instead, the SIAM hydraulic modeling results indicate that the Poudre River in Fort Collins is on the cusp of shifting to a flow and sediment regime similar to current conditions in Timnath downstream of I-25.

The SDEIS only addresses the risk of lost flood conveyance downstream of I-25 (SDEIS main report p. 4-159). This implies that effects in Fort Collins will be negligible despite increased risk of sediment accumulation, channel shrinking, woody vegetation encroachment, and increased potential of debris impacts to flood conveyance at bridges and other hydraulic structures. This implicit conclusion is not supported with any empirical or modeling evidence in the SDEIS documentation. Although Alternative 2 will likely result in increased vegetation encroachment and reduce channel conveyance capacity in the absence of periodic channel maintenance flows, it would not reduce the magnitude of the most extreme flow events delivered to the Fort Collins river segment (e.g., 50-100+ year floods). This means that 100 year and larger flood stages could appreciably increase and create a public safety and cost issue for Fort Collins. Additional analysis is needed to address the risk of lost flood conveyance in Fort Collins.

NEPA requires an "accurate scientific analysis." 40 C.F.R. § 1500.1. "For this reason, agencies are under an affirmative mandate to 'insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements …" *Envtl. Defense v. Corps of Engineers*, 515 F. Supp. 2d 69, 78 (D.D.C. 2007). To address these deficiencies, the Corps must conduct further analyses in a revised DEIS or supplement to the SDEIS. Under NEPA and the CWA, the Corps "must articulate why it has made its decision with sufficient clarity that others affected by the decision and the Courts can understand it." *Crutchfield v. United States Army Corps of Engineers*, 154 F. Supp. 2d 878, 899 (E.D. Va. 2001).

7.3 INCORRECT ANALYSIS OF STREAM MORPHOLOGY AND SEDIMENT TRANSPORT

Effects Report, Section 3.6.2, Spells Analysis at Representative Cross Sections for Flows that Initiate Motion of Bed Material, Page 3-9

Statement: "*The spells analysis suggests that the time between occurrences of bed material motion is not generally increased under Alternative 2, so to the extent that colonization of vegetation is dependent on the existence of a stable substrate, no significant change in the rate or extent of new colonization is expected.*"

Comment: SDEIS analyses of sediment mobilization use inappropriate methods to estimate the flows at which river bed flushing and rejuvenation occur. The equation from Ackers and White (1973; p.6-10 of Baseline Report) was not intended for this application nor calibrated for the prevailing grain sizes in the Poudre River in Fort Collins. The equation is used to adjust shear stress output from HEC-RAS modeling. This erroneous application of shear stress "partitioning" biases the results such that it appears that there is little sediment flushing occurring under baseline conditions, and ultimately masks the net reduction in sediment flushing that occurs under Alternative 2.

To investigate this bias, Fort Collins re-ran the HEC-RAS model used in the SDEIS analyses and computed four standard estimates of shear stress using main channel shear, hydraulic depth and friction slope, maximum depth and friction slope, and a well-known standard relationship for estimating grain shear in gravel bed rivers. All these accepted methods result in significantly greater sediment flushing and mobilization potential compared to values reported in the SDEIS. *See* Bledsoe, B. (2015). Technical Memorandum: Northern Integrated Supply Project - Supplemental Draft EIS Flushing Flow Analysis.

This one source of bias in shear stress estimates produces errors averaging 52% with some errors exceeding 80% at the SDEIS "representative" cross-sections that were selected in the Fort Collins reach. Furthermore, the selection of single "representative" cross-sections to represent several thousand feet of river channel in the SDEIS is not explained and justified. Based on analysis of HEC-RAS model outputs, some of these sections appear to not be representative of reach wide conditions due to their hydraulic characteristics proximity hydraulics structures (see for example the "representative" cross-section at station 231,351 which is located immediately upstream of a bridge in Fort Collins).

The Corps must conduct additional studies using appropriate methodologies to address the deficiencies described above, specifically with respect to using standard estimates of shear stress using main channel shear, hydraulic depth and friction slope, maximum depth and friction slope, and a well-known standard relationship for estimating grain shear in gravel bed rivers, as opposed to using the equation from Ackers and White identified above.

7.4 INCORRECT DATA ON GRAIN SIZE

Effects Report, Section 3.6.2, Spells Analysis at Representative Cross Sections for Flows that Initiate Motion of Bed Material,Ppage 3-9

> Statement: "*The spells analysis suggests that the time between occurrences of bed material motion is not generally increased under Alternative 2, so to the extent that colonization of vegetation is dependent on the existence of a stable substrate, no significant change in the rate or extent of new colonization is expected.*"

Comment: The grain size data that were chosen to estimate NISP effects on river bed flushing and mobility are biased toward the coarsest material relative to data obtained through more intensive substrate monitoring conducted by Colorado State University ("CSU"). By utilizing the coarsest available grain size data (collected using sampling methods that yield less accurate estimates than

the CSU samples), the SDEIS analyses are further biased (in conjunction with the first point in the paragraph above) toward underestimation of differences in how often and effectively the river bed is cleaned by current flows versus Alternative 2 flows.

The CSU grain size data were provided to the Corps and NISP consultants and are acknowledged and reported in the Baseline Report (Figure 3.8, p. 3-13 of Baseline Report). However, these data do not appear in subsequent grain size plots and analyses. As a result of the combined influence of underestimated shear stresses and selection of very coarse grain sizes, as described in the previous comment, the SDEIS generally contends that extreme flows are required for river bed cleaning in Fort Collins. By contrast, standard methods indicate that sediment can be flushed and the river bed rejuvenated with flows of 2,000 to 3,500 cfs at most locations. Bledsoe, B. (2015). Technical Memorandum: Northern Integrated Supply Project - Supplemental Draft EIS Flushing Flow Analysis. This is important because Alterative 2 can divert 1,000 cfs. This amount of flow diversion would be the difference between flushing and not flushing the river bed in many years. These errors propagate through all the other analyses of physical-biological linkages (e.g., modeling future trout habitat or the risk of algae proliferations). The lack of bed mobility has broad implications to the Poudre River ecosystem as discussed throughout the comments herein.

NEPA requires that the Corps conduct additional studies using appropriate methodologies to address the deficiencies described above, specifically with respect to the use of CSU grain size data and the determination of flushing flows.

7.5 AUGMENTATION PROGRAM'S ABILITY TO MAINTAIN THE ENVIRONMENT

SDEIS Appendix F, Section 3.2.4, Low Flow Augmentation Release (FW-04)

Statement: "*To further improve the cold water fishery on the Poudre River from the canyon mouth through Fort Collins, Northern Water would integrate a flow augmentation program that would release water from Glade Reservoir to improve Poudre River streamflow from the canyon mouth through Fort Collins.*"

Comment: The Augmentation Program is narrowly conceived. An extensive body of science is clear that a range of flows from low to high is necessary for maintenance of the environment. At present, the plan only proposes the maintenance (at most times) of 10 cfs.

There is no proposal for impacts to flushing flows, which might include periodic larger flow releases, and/or releases after a major sediment producing event in the watershed such as wildfire or landslide activity. High flows are essential to reduce adverse impacts that will occur from sediment deposition, channel narrowing from vegetation encroachment, and reduced biological functioning of the river through Fort Collins.

Although the proposed Augmentation Program is welcome, 10 cfs is not sufficient for its purposes. According to widely accepted instream flow methods such as Colorado Water Conservation Board's R2CROSS approach, 10 cfs is substantially below flow levels required to maintain the environment to a reasonable degree. Dr. Kevin Bestgen, a fisheries expert at CSU, has several years of trout monitoring data collected from the Poudre River in Fort Collins that support at least a 20 to 30 cfs base flow in fall/winter. (Fort Collins' Ecological Response Model (as discussed

in Section 10 of these comments) is informed with this information, and its purpose is to identify probable ecological responses to a range of potential future changing conditions related to streamflows and important secondary factors affecting the river system. It defines clear quantitative targets for low and high flows that are a necessary part of the conversation on mitigation.)

Flushing/bypass flows for mobilizing coarse substrates would reduce the extent of fine sediment deposition and accumulated algae, as well as decrease the likelihood that physical habitat will continue to degrade to a level that produces additional, detectable biological impacts. In the absence of flushing flows, existing physical habitat will be negatively affected in the future as the river channel and its substrate characteristics (e.g., extent of interstices clogged with fine sediment, amount of algae) evolve with ongoing changes in water management.

The Augmentation Program ignores the fact that the above-described response will occur irrespective of base flows because such low flows are incapable of rejuvenating the river bed to maintain habitats required by trout and aquatic insects.

As currently formulated, the Augmentation Program would not avoid or minimize the diversions under the Project which occur during periods of high flows thereby reducing flushing flows. The Augmentation Program would instead maintain certain flows during periods of low flows. It appears that the Augmentation Program was conceived to mitigate and compensate for certain effects of NISP at low flow, and not to avoid and minimize its critical effects on flushing flows.

NEPA requires that the Corps conduct further analyses to address the deficiencies described above, specifically with respect to the ability of the Augmentation Program to maintain the environment with only the maintenance of 10 cfs (at mot times) and no flushing flows. Further, under NEPA and the CWA, the Corps must require measures to minimize the impacts to flushing flows. *See* 40 C.F.R. § 1508.20. *See also* 40 C.F.R. § 230.10. The Corps must require clarification and substantiation of the assertion that the Augmentation Program is avoidance and minimization, as opposed to mitigation.

7.6 NEED TO ADDRESS FLOODING AND STORM WATER ISSUES

SDEIS Appendix F, Section 4.3.1, Stream Channel and Habitat Improvement Plan (AG-01)

Statement: "*Northern Water would provide funding for a stream channel and habitat improvement plan for the Poudre River from the Poudre Valley Canal to its mouth at the South Platte River. The stream channel and habitat improvement plan would address and mitigate Poudre River water related resources, including aquatic, stream morphology, water quality, riparian and special status species. […] NISP commits to spending up to $1.0 million to develop the stream channel habitat and improvement plan. This funding is in addition to other commitment made in this Conceptual Mitigation Plan.*"

SDEIS Appendix F, Appendix A, Table A-1

Statement: "*Item No. AG-03 Implement and fund Poudre River Adaptive Management Program ($5 million + $50,000/yr for 20 years).*"

Comment: Channel contraction and vegetation encroachment from NISP will likely have significant adverse effects on base flood elevations and the resulting extent of flood inundations during large recurrence interval floods such as, the 100- and 500-year flood events. Fort Collins review of the SDEIS indicates a high probability that the capacity of the Poudre River channel to convey floodwater will be materially reduced under the NISP proposed action; therefore, new river modeling, planning and prevention measures will need to be put in place to ensure the safety of the citizens of Fort Collins. Unless addressed at this time, subsequent costs of designing, constructing and maintaining additional flood protection facilities or modifying existing structures would be borne by the citizens of Fort Collins. The mitigation plan states that NISP commits to spending up to $1.0 million to develop the stream channel and habitat improvement plan. As noted above, additional evaluation is needed before approval of the Project in order to better understand possible impacts to the floodplain and determine mitigation alternatives as well as costs and funding for the mitigation.

The District proposes to develop the stream channel habitat and improvement plan. The adequacy of such a plan is speculative at this time because it has not been developed. Because the Corps has not adequately addressed the effects of sedimentation in Fort Collins, the extent of the need for mitigation is uncertain. Further, details of that plan are unknown at this time and the $1.0 million budget's adequacy is arbitrary and capricious without further information. Further, there is no certainty that the any of the recommendations from that plan will be funded and implemented.

With the actual mitigation activities being uncertain, the proposed mitigation activity of funding the "Poudre River Adaptive Management Program" for an amount ranging from $5-6 million ignores the potential need for more significant mitigation actions and caps the amount provided and the time frame for the mitigation program.

In the SDEIS, the Corps must ensure that environmental effects will not be "overlooked or underestimated only to be discovered after resources have been committed or the die otherwise cast." *Skinner*, 903 F.2d at 1540. As discussed above, NEPA and the CWA require that the Corps provide in the SDEIS additional information on the stream channel habitat and improvement plan. If the Corps approves NISP, it must require as condition of the permit that the District fund any recommendations from the plan and adequate mitigation.

[Remainder of Page Left Blank Intentionally]

SECTION 8: AIR QUALITY AND CLIMATE CHANGE COMMENTS

Fort Collins has various concerns related to air quality and climate change impacts and issues in the SDEIS. Climate change is of significant importance to Fort Collins, as noted in Fort Collins Climate Action Plan. *See* http://www.fcgov.com/climateprotection. As discussed in detail below, the SDEIS does not include all sources of air pollution or greenhouse gases ("GHGs") and does not evaluate whether all federal, state, and local air quality regulations and rules will be met as a result of implementation of the Project. The Corps' assessment of the air quality and climate change impacts is not a mere formality. The SDEIS must provide a "full and fair discussion" of those indirect impacts. 40 C.F.R. § 1502.1. This "comprehensive 'hard look' mandated by Congress and required by statute must be timely, and it must be taken objectively and in good faith, not as a exercise in form over substance, and not as a subterfuge designed to rationalize a decision already made." *Metcalf v. Daley*, 214 F.3d 1135, 1142 (9th Cir. 2000). Further, the conformity regulations promulgated pursuant to the Clean Air Act create separate procedural and substantive requirements that the Corps must meet. *See* 40 C.F.R. Part 93 (conformity regulations). However, the SDEIS defers such analysis to an uncertain point in the future.

In violation of NEPA and the Clean Air Act, the SDEIS does not fully analyze these impacts. Because of the Corps' inadequate assessment, the air quality and climate change impacts are understated. Additionally, Fort Collins and other stakeholders cannot fully or meaningfully analyze these impacts and their effects. Revised and additional analyses are required.

8.1 COMMENTS REGARDING INCOMPLETE ANALYSIS RELATED TO AIR QUALITY

8.1.1 No Analysis of Impacts from Increased Traffic

SDEIS Section 3.14.4.1, North Front Range Transportation and Air Quality Planning Council, Page 3-177

> Statement: "*A project must come from a conforming transportation plan and improvement program (40 CFR 93.115) before a conformity determination can be made for it. The design and concept for the proposed project must be adequately defined and must remain consistent with the project's definition in the conforming RTP and TIP. If the project changes in concept or design during the planning process, or if it was not originally included in the RTP and TIP, the regional conformity analysis would need to be revisited before the project can proceed.*"

Comment: The air quality analysis for the realignment of U.S. 287 did not account for the estimated 439,300 annual visitor day increase for recreational use at Glade Reservoir and its long-term impact on vehicle miles travelled ("VMT") in the ozone nonattainment area. It is important that this traffic volume increase be communicated to the North Front Range Metropolitan Planning Organization, the Air Pollution Control Division of the Colorado Department of Public Health and the Environment, the Colorado Department of Transportation, and the Upper Front Range Transportation Planning Region because it will alter the results of the air quality evaluation and the regional ozone conformity analysis.

NFRMPO's conformity analysis depends on a detailed traffic analysis conducted for the entire area covered by the MPO. This includes assigning employment and traffic generators to each of the traffic analysis zones ("TAZs") covered by the model, including the TAZ in which the proposed Glade Reservoir is located. There is no indication in NFRMPO's RTP and conformity analyses for 2035 or 2040 that any of the recreational traffic for the proposed Glade Reservoir has been included. *See e.g.,* NFRMPO, Upper Front Range 2035 Regional Transportation Plan (2008); North Front Range Land Use Allocation Model (June 17, 2015).

The modeling of emissons associated with the recreational VMT should also make adjustments to the vehicle mix to reflect the trucks hauling boats and campers which will increase future air emissions and further impact ozone level predictions. If the assumption is that this represents a shift of visitor days from Horsetooth Reservoir or other reservoir/lakes, then the annual economic benefit from recreation at Glade Reservoir of $13.2 million in SDEIS Section 5.20.2.3.1 needs to be modified. Further, the analysis should also account for increased VMT associated with longer trip lengths to Glade. Per 40 C.F.R. § 93.156(b), the ozone conformity determination must be prepared and made available to the public for review and comment before it is finalized.

The VMT estimates need to be revised to include increased traffic to Glade Reservoir and this information should be transmitted to all appropriate agencies listed above. Fort Collins and other stakeholders must be afforded the opportunity to review and comment on this information. 40 C.F.R. § 93.156(b). A regional ozone conformity determination needs to be conducted only after all air quality impacts from this project have been quantified and included in the conformity determination, and this information must be provided to Fort Collins pursuant to the Clean Air Act.

SDEIS Section 4.13.3.1.1, Glade Reservoir, Page 4-331

Statement: "*Changes in traffic volumes from reservoir construction would be similar to the effects of constructing the Cactus Hill Reservoir described in the No Action Alternative.*"

Comment: The description of construction traffic for the Cactus Hill Reservoir in Section 4.13.2.1 for the No Action Alternative states that construction traffic and heavy vehicles necessary for site development would likely remain on-site for the duration of construction and would not contribute to daily traffic. The construction phase of Glade Reservoir is estimated to be 5 years, and during this time, movement of heavy vehicles for removal of construction and demolition waste would be expected. These activities were not included in the 2013 Air Quality Analysis Memo (GEI 2013) as part of the modeling effort although these emissions will likely contribute to increases in ozone in the nonattainment area.

The Corps must revise or supplement the SDEIS to include additional analyses of the priority pollutants for movement of construction and demolition waste to address the deficiencies described above.

SDEIS Section 4.14.1, Methods, Page 4-337

Statement: "*The realignment of U.S. 287 was included in the STIP for regional ozone conformity determinations by NFRMPO as discussed in Section 3.14.4.1.*"

Comment: The estimated 439,300 annual visitor day increase for recreation at Glade Reservoir and its long-term impact on VMT in the region have not been considered in the conformity analyses for any conforming Regional Transportation Plan (RTP) or the Transportation Improvement Program (TIP) by NFRMPO. As a result, the emissions associated with these vehicle trips must be included in the general conformity analysis.

The RTP and TIP must include increased vehicle traffic and the regional ozone conformity determination by NFRMPO should be revisited due to the absence of this data. Further, the general conformity analysis to be developed by the Corps must include the emissions from these vehicle trips if they have not been modeled in the NFRMPO conformity analysis approved by FHWA.

SDEIS Section 4.14.3.1.1, Glade Reservoir, Page 4-339

Statement: "*The reduced vehicle emissions from a shorter U.S. 287 may be somewhat tempered by steeper grades associated with a portion of the proposed realignment.*"

Comment: The increased traffic associated with recreational use at Glade Reservoir will include trucks, hauling boats, and campers, that when considered in VMT modeling, will increase, not decrease, vehicle emissions. Vehicle emissions would significantly increase resulting from the large VMT increase for recreation; the resulting air quality impacts will include long-term direct and indirect effects; and impact is expected to be at least moderate because the effects would result in clearly detectable change with measurable effects.

The Corps must account for all of the vehicle emissions associated with new recreational trips in its general conformity analysis. The modeling to support this general conformity analysis must include appropriate emissions factors to reflect the vehicle mix associated with boat hauling, campers and other recreational vehicles. Aside from the general conformity analysis, the Corps must disclose the traffic and emissions impacts of this recreational traffic in a revised SDEIS to comply with NEPA.

8.1.2 Analysis Missing Numerous Air Pollution Sources

SDEIS Section 4.14.1, Methods, Page 4-336

Statement: "*Air quality can potentially be affected by short-term direct effects associated with construction of the alternatives (e.g., emissions from construction equipment, workers' vehicles, delivery vehicles, and fugitive dust) or by long-term indirect effects such as changes to transportation (e.g., the realignment of U.S. 287) or from project operations (e.g., emissions associated with pumping).*"

Comment: The SDEIS air quality analysis, including the supporting analysis (2013 GEI), omitted numerous long-term sources of emissions of criteria pollutants and particulates and did not consider any human health or environmental impacts from air toxics. The following significant sources of air emissions were missing from the air quality analysis, such that the analysis underestimates emissions and air quality impacts:

- Criteria pollutant and particulate emissions associated with large VMT increases for recreation at Glade Reservoir.

- Criteria pollutant emissions associated with the new recreational activities at Glade the Corps seeks to claim credit for in its recreational and economic analyses, including boats, jet skis, generators and other sources of non-road mobile source emissions. The emissions of these off-road sources can often be quite high, because they have not been subject to as stringent emissions regulations as on-road vehicles.
- Criteria pollutant emissions associated with pumping during long-term Project operations (e.g., NO_x ozone precursors).
- Air toxics sources:
  - VMT increase for recreation to Glade Reservoir and potential for long-term human health impacts.
  - Construction emissions direct health impacts on local residents.
  - Construction emissions indirect impacts such as deposition of air toxics onto soils and surface waters where they are taken up by plants and ingested by animals and eventually magnified up through the food chain.
- Emissions from vehicle exhaust and fugitive dust emissions from proposed mitigation plan activities such as:
  - Channel and habitat improvements (Appendix F, Section 4.3.2, Page 68).
  - Revegetation efforts to support establishment of native wetland and riparian species on exposed sediment (Appendix F, Section 4.3.4, Page 79).

The Corps must include in a revised or supplement to the SDEIS, as well as its draft and final general conformity analyses, additional quantitative analyses of air quality sources to address the deficiencies described above. The conformity analysis must account for the criteria pollutant emissions identified in the first three bullets above.

SDEIS Section 4.14.1, Methods, Page 4-336

Statement: "*The assessment of predicted effects on air quality is presented in detail in the 2013 Air Quality Analysis Memo (GEI 2013).*"

Comment: The Air Quality Analysis Memo (GEI 2013) presents an incomplete analysis of air quality impacts from NISP for the following reasons:

- The evaluation does not look at the total of all direct and indirect emissions to determine exceedance of the general conformity de minimis thresholds in 40 CFR § 93.153.
  - Only short-term emissions from construction activities were considered for compliance with National Ambient Air Quality Standards ("NAAQS").
- The evaluation of air quality impacts from U.S. 287 realignment does not consider the significant long-term change in VMT expected due to travel to access the new recreation at Glade Reservoir.
- It does not include emissions associated with recreational sources at Glade Reservoir and emissions associated with the electricity necessary for pumping in all alternatives.
- A comprehensive air quality analysis would quantify and evaluate the impacts of additional pollutants beyond the six criteria air pollutants addressed in the SDEIS. The Clean Air Act also regulates hazardous and other air pollutants that can impact human health and the environment.

The Corps must include in a revised or supplement to the SDEIS, and the general conformity analyses, additional evaluations of these air quality impacts to address the deficiencies described above.

SDEIS Section 4.14.6, Unavoidable Adverse Impacts, Page 4-342

Statement: "*During the general conformity process, the CDPHE Air Pollution Control Division (APCD) would review NISP to determine if NISP conformed to the SIP for NO_x. During its conformity analysis, the APCD would determine if the Project's estimated emissions are included in the state's emission inventory.*"

Comment: The analysis of air quality impacts (GEI 2013) did not consider long-term emissions of NO_x, SO2, CO, and particulates associated with the annual electricity requirement of 61,302,050 kWh for pumping for Alternative 2 with no reclamation and 48,135,987 kWh annually for pumping for Alternative 2 with reclamation in determining NAAQS compliance.

Estimated NO_x emissions for pumping would be 74 tons/year for pumping for Alternative 2 with no reclamation and 58 tons/year for pumping for Alternative 2 with the Reclamation Option. These estimates were calculated using the 2014 regional marginal emissions factors and need to be included during the ozone conformity analysis to determine compliance with NAAQS.

Additional analyses of priority pollutants from these vehicle emissions should be completed to address the deficiencies described above.

SDEIS Section 4.14.6, Unavoidable Adverse Impacts, Page 4-342

Statement: "*Unavoidable long-term non-construction related impacts on air quality may occur periodically associated with the exposed shorelines of reservoirs that may cause fugitive dust emissions.*"

Comment: The SDEIS and supporting air quality analysis (GEIS 2013) only estimate fugitive dust emissions from construction activities and do not attempt to estimate fugitive dust emissions from exposed shorelines at Glade Reservoir. NISP hydrologic modeling on Glade Reservoir water levels and is available to estimate frequency and extent of reservoir draw down from which an estimate of fugitive dust emissions can and must be developed. These data are needed to determine the significance of impacts from fugitive dust.

The Corps must include in a revised or supplement to the SDEIS, and its general conformity analysis, additional analyses of priority pollutants from these missions to address the deficiencies described above.

SDEIS Section 5.14.2, District's Preferred Alternative (Alternative 2), Page 5-237

Statement: "*Most direct effects on air quality would occur with the construction of Glade and Galeton Reservoirs and associated facilities and the realignment of U.S. 287.*"

Comment: Long-term direct impacts from NO_x from increased VMT and a shift in vehicle mix resulting from recreation at Glade Reservoir, as well as the emissions from boats, jet skis and other recreational equipment, were not evaluated. Also missing was a quantitative analysis of long-term

direct effects of fugitive dust resulting from low water levels in Glade Reservoir during drought periods, and an analysis of direct impacts from air toxics. These are considered direct effects according to Section 4.1.1.1 Direct and Indirect Effects, of the SDEIS because they occur at the same time and place as the activity and impact a large number of recreational users. The Corps must include in a revised or supplement to the SDEIS additional analyses to address the deficiencies described above.

8.1.3 Inadequate Air Quality Analysis May Lead to Violation of NAAQS For Ozone

SDEIS Section 4.14, Air Quality, Page 4-336

Statement: "*The marginal nonattainment designation does not impose any new planning requirements on Colorado at this time; however, the nonattainment area must meet the standard before 2015 or new requirements may be imposed.*"

Comment: The Environmental Protection Agency ("EPA") lowered the 8-hour ozone standard from 0.084 ppm to 0.075 ppm in 2008. In 2010, EPA reconsidered the 2008 standard and proposed a further tightening of this standard to a range between 0.060-0.070 ppm with several subsequent delays in implementation to date. Regardless of where within the range EPA sets the new ozone standard, meeting it will require unprecedented efforts for Colorado according to the Ozone State Implementation Planning 2010 Progress Report to the Governor. This report also states that ozone State Implementation Plan (SIP) planning is presently the Regional Air Quality Council's highest priority. Stringent requirements from stationary sources, transportation, and other source categories are expected and should be considered likely requirements for implementation of NISP.

The Corps must include in a revised or supplement to the SDEIS a regional ozone conformity analysis taking into account the lowering of ozone standards since the original NAAQS analysis. A lower ozone standard will increase the chances of NAAQS noncompliance.

SDEIS Section 4.14.3.1.1, Glade Reservoir, Page 4-339

Statement: "*NFRMPO determined that a regional ozone conformity analysis was not needed because the new route would be shorter than the existing alignment.*"

Comment: The impact of increased VMT and changes in the vehicle mix from Glade Reservoir recreational users were not included in any regional ozone conformity determination by the North Front Range Metropolitan Planning Organization. Therefore, the realignment of U.S. 287 was not adequately defined. 40 C.F.R. § 93.115 requires the regional conformity analysis to be revisited before the Project can proceed. The regional ozone conformity analysis needs to be revised to include all air pollutant sources.

SDEIS Section 5.14.5, Climate Change, Page 5-238

Statement: "*Given the predictions of increased levels of ground-level ozone in already-polluted areas due to climate change, short-term construction emissions from any of the alternatives could contribute to short-term ozone exceedances when combined with other emissions in the area. This would be a moderate cumulative effect because the effect would be short-term associated with construction and short-term meteorological events.*"

Comment: This analysis did not factor in the long-term increases in VOCs and NO_x associated with increased VMT for recreation at Glade Reservoir, emissions from recreational equipment, and for operational pumping of water. These emissions would occur throughout the life of the Project and thus would be long-term. Frequent exceedances of ozone standards are anticipated when long-term NISP emissions are combined with other regional emissions, higher ozone levels from increased temperatures due to climate change, and expected lowered ozone standards. The cumulative impacts likely qualify as major impacts defined as effects that would be readily apparent with substantial consequences (e.g., frequent ozone exceedances in the nonattainment area).

Further, the conformity rules prohibit even short-term violations or exacerbation of the conformity rules. The Corps will need to demonstrate conformity consistent with the criteria of the general conformity rule. The SDEIS defers this analysis to some unknown point in the future. The regional ozone conformity analysis needs to be revised to include all air pollutant sources.

8.1.4 Determination of Air Quality Impacts and Their Significance Did Not Consider Requirements of All Air Quality Regulations

SDEIS Section 4.14.7, Impact Summary, Page 4-344

Statement: "*During construction, all alternatives would have estimated average annual emissions of NO_x greater than the conformity de minimis level of 100 tons/year for the ozone nonattainment area.*"

Comment: An evaluation of air quality impacts should be based on meeting all regulatory requirements of the Clean Air Act, not just meeting NAAQS. The Corps must consider the following factors to ensure compliance with all federal, state, and local air quality regulations:

1) If the effects would cause an air quality standard to be violated;
2) Activities or emissions that would result in a cumulatively considerable net increase of O_3 in the nonattainment area;
3) Activities that expose sensitive receptors to substantial pollutant concentrations;
4) Fugitive dust emissions from demolition activities that could impair visibility in a Federal Class I area located within 100 km of the proposed activities such as Rocky Mountain National Park (Clean Air Act, Section 169A); and
5) Activities or emissions that would be inconsistent with Colorado's Revised Regional Haze Plan (Colorado Department of Public Health and Environment ("CDPHE") 2011).

The Corps must include in a revised or supplement to the SDEIS additional analyses to address the deficiencies described above. Specifically, the above criteria must be added to the SDEIS for determining air quality impacts and their significance.

SDEIS Section 5.14.2, District's Preferred Alternative (Alternative 2), Page 5-237

Statement: "*The increases in emissions are considered a minor cumulative effect because they would be short-term and the alternative would need to undergo a general conformity analysis that would consider other regional contributions to ensure that the region remains in compliance with NAAQs.*"

Comment: The air quality analysis failed to consider all long-term sources of NO_x emissions (e.g., travel for recreation at Glade Reservoir, recreation at the Reservoir, and operational water pumping). The direct and indirect effects of the short-term and long-term NO_x were therefore not quantified. A comprehensive analysis would likely result in at least moderate effects (e.g., clearly detectable change with measurable effect as defined in Section 4.1.1.3, Intensity and Magnitude of Effect of the SDEIS). Between an insufficient analysis of all emission sources and with the recent tightening of ozone standards, the Corps must require a regional ozone conformity analysis. The Corps must include in a revised or supplement to the SDEIS additional analyses to address the deficiencies described above.

8.2 COMMENTS REGARDING INCOMPLETE ANALYSIS RELATED TO GREENHOUSE GAS EMISSIONS

8.2.1 Analysis Missing Numerous Greenhouse Gas Emission Sources

SDEIS Section 4.14.1, Methods, Page 4-337

Statement: "*The estimated long-term greenhouse gas (carbon dioxide) emissions that could result under each alternative were based on the projected energy requirements for pumping for the alternatives (BBC 2014).*"

Comment: The methods used for estimating greenhouse gas ("GHG") emissions are inadequate for determining NISP GHG increases or impacts for the following reasons:

- All GHGs are referred to as CO_2 emissions. This indicates that additional GHGs with higher global warming potentials such as CH_4, and hydrofluorocarbons ("HFCs") were omitted, and as a result, total GHG emissions are underestimated.
- Significant sources of GHGs from the large VMT increase to and from Glade Reservoir for recreation were omitted.
- The Alternative 2 evaluation must include increases in GHG emissions from boats, jet skis, and other equipment used in the reservoir.
- Increases in emissions associated with waste disposal from recreational users were not included in the analysis.
- There is a requirement for additional wastewater treatment associated with several proposed alternatives that would result in increased emissions of GHGs (CO_2, CH_4, and N_2O) for new and existing wastewater treatment facilities. These have also been omitted from the analysis.

The long-term effects from all the GHG sources that were omitted from this analysis should have been included in the analysis because they can be determined using existing national and international GHG methods and protocols and because they would significantly change the conclusion of the analysis.

The Corps must include in a revised or supplement to the SDEIS additional analyses to address the deficiencies described above. Specifically, the SDEIS must include a more detailed inventory of all GHG sources and a description of methods and calculations is needed to determine GHG impacts.

SDEIS Section 5.14.2.1, Long-Term Emissions of Carbon, Page 5-237

Statement: "*The cumulative effects of the carbon dioxide emissions on climate change are unknown.*"

Comment: The physical link between increasing temperatures and increasing concentrations of GHGs has been documented by a large body of research.[3] The U.S. National Climate Assessment,[4] a report compiled by a team of over 300 experts who collected, evaluated and integrated observations and research on climate change in the U.S., is available to estimate impacts to human health and the environment. Hence, there is no basis for claiming that the cumulative impacts of GHG emissions are unknown. Although a detailed, quantitative evaluation of the cumulative impacts of increased GHG emissions from NISP on the various resources considered in the SDEIS may be premature, the Corps needs to acknowledge the potential for impacts such as increased global temperatures resulting from NISP's GHG emissions. The Corps must include in a revised or supplement to the SDEIS additional analyses to address the deficiencies described above.

SDEIS Section 5.14.6, Impact Summary, Page 5-239

Statement: "*The estimated electrical energy used by the alternatives would be about 0.1% of the energy used in Colorado in 2012 (Section 4.22). This contribution to climate change would be a minor cumulative effect because the effect would be relatively small compared with the regional total annual emissions of GHGs.*"

Comment: The estimation of GHG emissions in the SDEIS only quantifies one source of GHG emissions–from CO2 emissions from electrical energy use for pumping water. This is an incomplete estimate of total GHG emissions for the Project alternatives and leaves out:

- The CO_2, N_2O, CH_4, and HFC emission contributions from increased ground transportation for recreational use at Glade Reservoir;
- Emissions of other GHGs (N_2O) from electricity use for pumping;
- The CO_2, N_2O, and CH4 emissions from disposal of short-term construction and demolition wastes
- The CO_2, N_2O, and CH4 emissions from long-term solid waste disposal from recreational users at Glade Reservoir; and
- The increases in CO_2, N_2O, and CH_4 emissions associated with increased wastewater treatment for several alternatives.

There are numerous national and international protocols (e.g., ICLEI Community Protocol, World Resources Institute (WRI) GHG Protocol, etc.) for estimating GHG emissions from multiple emission sources. Furthermore, it is not valid to compare electrical energy use for pumping for NISP to that of the electricity use of the entire state of Colorado during 2012 and then extrapolate impact on climate change based on this comparison. There are local and regional differences in the

[3] 2007. IPCC WGI Fourth Report: Climate Change 2007: The Physical Science Basis, Contribution of Working Group I to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change, Summary for Policymakers, http://www.offnews.info/downloads/SPM2feb07.pdf.

[4] Mellilo, Jerry M., Terese (T.C.) Richmond, and Gary W. Yohe, Eds., 2014: *Climate Change Impacts in the United States: The Third National Climate Assessment.* U.S. Global Change Research Program, 841 pp. doi:10.7930/JoZ31WJ2.

GHG emissions from electricity depending on if the source is clean (e.g., renewable energy). There is a state-level GHG emissions estimate (not provided in the SDEIS), but there is no known "regional total annual emissions of GHGs." This determination of a minor cumulative effect is not based on valid or transparent data.

The Corps must include in a revised or supplement to the SDEIS an analysis of the total GHG emissions that includes all major GHG sources and uses valid comparisons. Additionally, the Corps must provide an adequate factual basis for its determination of minor cumulative effect. The Corps cannot rely on "conclusory assertions that an activity will have only an insignificant impact on the environment." *Ocean Advocates v. U.S. Army Corps of Eng'rs*, 402 F.3d 846, 864 (9th Cir. 2004).

8.2.2 Claimed Minor Impacts on Greenhouse Gas Emissions

SDEIS Section 4.14.7, Impact Summary, Table 4-96. Impacts to air quality, Column Predicted Annual Carbon Dioxide Emissions for Project Operation at Full Utilization, Page 4-343

Statement: "*Alternative 2 Reclamation Action Option: Construction over an estimated 9.1 years would have a short-term minor impact on air quality.*"

Comment: Annual carbon dioxide emissions for Project operation at full utilization of 37,259 metric tons for Alternative 2 with Reclamation Action Option do not constitute a minor impact on air quality from a climate change perspective. Moderate effects are defined in Section 4.1.1.3 Intensity and Magnitude of Effect in the SDEIS as effects that would result in clearly detectable change with measurable effects. This amount represents 70% of the 2014 GHG emissions from Fort Collins' entire municipal operations (2014 Comparative Municipal GHG Report) and 80% of the 2013 GHG emissions from Colorado State University (one of the 3 top GHG sources within Fort Collins city limits (see reporting via EPA map located at: http://www.epa.gov/ghgreporting/). For comparison, under the EPA's Mandatory GHG Reporting Rules, this level of emissions constitutes a major source. The Corps' characterization of these emissions as "minor" when the EPA characterizes lower levels to be "major" is arbitrary and capricious. The Corps must include in a supplement to the SDEIS additional analyses to address the deficiencies described above.

8.3 CUMULATIVE EFFECTS

SDEIS Section 5.14.6, Impact Summary, Table 5-54, Page 240

Statement: "*When combined with RFFAs and climate change, construction would have a short-term minor impact on air quality. Exposed reservoir shorelines could periodically contribute to local fugitive dust. Operations would contribute to the increase in the regional emissions of carbon dioxide. The cumulative effects on air quality would be minor because the incremental increase in carbon dioxide emissions would be relatively minor compared with the regional total annual emissions of GHGs*."

Comment: This summary is missing a comprehensive evaluation of the cumulative impacts of criteria air pollutants, air toxics, particulates, and all the relevant greenhouse gases over the lifetime of the Project. It fails to consider the residence time of any of these pollutants in the atmosphere and the full range of impacts on human health and the environment. This section and table is missing

numerous emission sources detailed in other comments by Fort Collins. The incomplete assessment is not adequate to make a determination of air quality. A more comprehensive set of air quality criteria should also be evaluated to determine the significance of impacts. Additionally, it is not valid to compare a partial Project GHG emissions inventory to a "regional total annual emissions of GHGs" that does not exist nor is referenced in the document. The Corps must include in a revised or supplement to the SDEIS additional analyses to address the deficiencies described above.

8.4 FUGITIVE DUST EMISSION CONTROL PLAN AND ADDITIONAL MITIGATION MEASURES FOR VEHICLE EMISSIONS

SDEIS Appendix F, Section 3.3.4, Air Quality (AQ-01), Page 50

Statement: "*To minimize and control fugitive dust, Northern Water would develop and implement fugitive particulate emission control plan that identifies specific steps that would be taken to minimize fugitive dust generation.*"

Comment: Additional mitigation measures must be implemented to control criteria and other air pollutants including:

- The fugitive particulate emission control plan should incorporate the following to the maximum extent feasible:
  - All haul roads would be covered in gravel with minimal silt content.
  - High winds restrictions to involve no earthmoving activities performed when local winds speeds exceed 30 miles per hour.
  - Implement engineering controls to prevent off-property transport.
  - Reduce vehicle speeds by establishing a maximum speed limit or install traffic calming devices to reduce speeds to a rate that prevents off-property transport of dust entrained by vehicles.
  - Unload truck beds and loader or excavator buckets slowly and at the lowest height possible.
  - Dust control measures should be incorporated to the maximum extent feasible during blasting operations. The following measures should be used during blasting activities:
  - Conduct blasting on calm days to the extent feasible. Wind direction with respect to nearby residences and sensitive environmental receptors should be considered.
  - Design blast stemmings to minimize dust and to control fly rock.
  - Install wind fence for control of windblown dust.
- If one or more of the suggested air quality significance criteria are met (proposed by the Fort Collins in the Comment to SDEIS Section 4.14.7 Impact Summary, Page 4-344), the following mitigation measures for mobile sources should be implemented:
  - Any off-road construction equipment (e.g., loaders, excavators, etc.) must be equipped with engines that meet the model year (MY) 2015 emission standards for off-road compression-ignition (diesel) engines. Older model year engines may also be used if they are retrofit with control devices to reduce emissions to the applicable emission standards.
  - Any on-road construction equipment (e.g., pick-up trucks at the construction sites) must be equipped with engines that meet the MY 2000 or on-road emission standards.
  - Any trucks used to transport materials to or from the construction sites must be equipped with engines that meet the MY 2010 or later emission standards for on-road heavy-duty

engines and vehicles. Older model engines may also be used if they are retrofit with control devices to reduce emissions to the applicable emission standards.

Implementation of these various engine control measures would substantially reduce NO_x and PM_{10} emissions; however, the extent of the reduction would vary based on the size (horsepower), age, and type of equipment. Controlling emissions from equipment operating on the construction site, including both off-road construction equipment and on-road pick-up trucks could reduce NO_x and PM_{10} emissions by over 80%. Controlling emissions from on-road heavy-duty diesel trucks could also reduce NO_x emissions by approximately 20% or more.

SECTION 9: RECREATION AND AESTHETICS COMMENTS

The Poudre River is a major recreational attraction in Fort Collins, attracting approximately over 500,000 visitor days a year. (SDEIS at page 3-195). These visitors' fish, hike, bicycle, boat, picnic, and view wildlife. The fishing is so good in the downtown reach of the river that creel counts for Segment B are consistently higher than any other reach on the Poudre River, including the canyon reach (personal communication, Kurt Davies, former Colorado Parks and Wildlife Poudre River fisheries biologist). Over many decades, Fort Collins has spent tens of millions of dollars beautifying, acquiring land, building recreation amenities, and restoration natural habitat. (City of Fort Collins Natural Areas Master Plan and Cache la Poudre River Natural Areas Management Plan Update). Fort Collins owns three parks on the River and over 1,800 acres of natural areas. In 2014, City Council adopted a Downtown Poudre River Master Plan that describes a vision for continuing to improve the most heavily visited reach of the River from Shields Street to Mulberry. This Master Plan describes a proposed whitewater park just below the College Avenue Bridge. The park includes storm water and habitat improvements and is estimated to cost approximately $8.5 million of which $7 million have been secured to date.

9.1 IMPACTS TO BOATING

SDEIS Section 4.16.3.3, Segment B

Statement: "*Segment B is popular for boating (canoeing and kayaking) and is the location of a proposed whitewater park. Target flows for quality boating opportunities are at or above 150 cfs. Compared with Current Conditions, Alternative 2 would result in an average reduction of 3 to 7 boating days per month (a total of 19 fewer days over the May-August period), resulting in a moderate to major adverse effect on boating opportunities in Segment B. Augmented winter flows in Alternative 2 would result in minor beneficial effects on recreational fishing opportunities in Segment B…*"

SDEIS Section 4.16.6, Unavoidable Adverse Impacts

Statement: "*Flow changes in Alternatives 2 and 3 would adversely affect boating and fishing opportunities along the Poudre River through Fort Collins (Segment B).*"

SDEIS Section 4.16.1

Statement: "*The 150 cfs threshold was based on comments on the DEIS from a local boating group on the minimum flows that would be needed to allow reasonable passage by canoe through Fort Collins; a 100 cfs threshold was previously used in the DEIS.*"

SDEIS Appendix F, Section 2.2.1, Summary of Effects

Statement: "*Reduced streamflow during the summer would result in a minor to moderate adverse effect on river-based boating in Segment B…*"

Comment: The SDEIS notes in Section 4 that there will be moderate to major adverse effect on boating opportunities in Segment B associated with Alternative 2. However, in Appendix F, that effect is inconsistently characterized as "minor to moderate." The inconsistency reveals a lack of the meaningful analysis required by NEPA.

Fort Collins does not agree with the characterization of boating impacts to Segment B as only minor or moderate. With boating days reduced by one-third on average, clearly this is a major effect, as described by the SDEIS's own terms. (See page 4-351 "Major effects would result in readily apparent effects with substantial consequences").

Paragraph 4.16.3.3 is unclear as to how many days at 150 cfs will be reduced. The SDEIS states that "Alternative 2 would result in an average reduction of 3 to 7 boating days per month." If this sentence is referring to all months it could be read to mean the loss of 36 to 84 days a year.

The SDEIS describes 150 cfs in Segment B as the minimum flows necessary for "reasonable" passage by canoe. Canoeing at 150 cfs is possible but that is the low end of the threshold (personal communications with local boaters). Between 75 and 100 cfs, the Poudre River through Fort Collins is just passable by inner tubes. The SDEIS should more definitively describe what "reasonable" means with respect to boating in Segment B.

The SDEIS notes minor beneficial effects to fishing due to winter time augmented flows in Segment B, although in a subsequent paragraph (see SDEIS Sections 4.16.3.3 and 4.16.6 respectively) it inconsistently notes that Alternative 2 would adversely affect fishing. However, as noted elsewhere in these comments, the SDEIS has failed to adequately analyze impacts to aquatic biological resources. Therefore, it is not yet possible to accurately characterize the impacts to fishing.

The Corps must include in a revised or supplement to the SDEIS an adequate analysis of the impacts on boating opportunities in Fort Collins, as described above. Further, the Corps must provide factual bases for its conclusions.

9.2 IMPACTS TO RECREATIONAL EXPERIENCES

SDEIS Section 4.16.3.3, Poudre River

Statement: "*Under Alternative 2, changes in streamflows are not expected to result in discernable visual impacts on recreational experiences along the Poudre River, or the availability of land-based recreational activities such as trail use, wildlife viewing, and photography. Likewise, wildlife-related recreation along the mainstem…would be unaffected*"

Comment: As noted elsewhere in these comments, Fort Collins has extensive concerns with the analyses of impacts to riparian and wetland vegetation. Moreover, Fort Collins asserts that the impacts will be greater than those described by the SDEIS, as described above. Over time, it follows that the degradation to the environmental resources of the river are likely to result in degradation to the user experience beyond a negligible or minor impact.

The SDEIS appears to conclude that there will be little to no impact to recreation activities (other than boating) along the Poudre in Fort Collins (SDEIS Table 4-100, page 4-360). However, based on a study commissioned by Fort Collins in 2008 ("Estimating Benefits of Maintaining Peak Instream Flows", Dr. John Loomis) a reduction in peak flow of 50% would reduce visitation to the river by approximately 33%.

The SDEIS describes a very large range of financial value associated with visits to the Poudre River Trail and visits to Natural Areas along the river. Figures for visits to Natural Areas range from approximately $2 million to approximately $14 million annually (SDEIS 3-196). Thus, the median value is $8 million. At approximately 500,000 visitors a year, that works out to $16 per visitor. Although it is not known precisely how many visitors are present in Natural Areas during May, June and July a safe assumption is that at least one-quarter of total annual visitors (approximately 125,000) are present during these months. Thus, a reduction of 33% of these visitors (approximately 42,000) at $16 a visit would represent an approximately $670,000 annual loss. While these figures may contain a margin of error, they are conservative and likely underestimate impacts, and suggest that there would be tangible economic losses related to flow depletions.

The Corps must include in a revised or supplement to the SDEIS additional analyses of the impacts on recreational experiences. Additionally, the Corps must explain its determination in the face of the contradictory evidence offered by Fort Collins. The Corps fails to comply with NEPA if it "offers an explanation which runs counter to the evidence . . . ." *Sierra Club v. U.S. Army Corps of Eng'rs*, 295 F.3d 1209, 1216 (11th Cir. 2002).

9.3 AESTHETIC IMPACTS

SDEIS Section: 4.18.3.3 Poudre River, Pages 4-373 to 374

Statement: "*Alternative 2 is predicted to have weekly average river stage declines of 0.5 foot or greater during the May through September period for 19% of the period of record. The increased frequency of predicted reductions in stage greater than 0.5 feet (almost twice as frequent as the other segments) in a segment of the river that is highly used, would likely be noticeable to many viewers familiar with the river in this segment ....*"

Comment: The SDEIS needs to provide a better assessment of the impacts of NISP on the visual resources of the Poudre River (specifically within Fort Collins), including the river channel, and wetland and riparian vegetation, based on the acknowledged reduced flow levels. However, the Corps must describe specifically how the aesthetics could change, such as the reduction of diversity and density of vegetative cover, reduction of wildlife, exposure of rip-rap and man-made structures and other factors due to the reduction of river flows. Data must be developed. For example, photo simulations and surveys could be conducted to evaluate the public's perception of lower river flows and the effects this could have on the visitor's experience and future urban and recreational development along the river corridor. Under NEPA, the Corps must require additional mitigation measures to address the deficiencies described above.

9.4 MITIGATION OF VISUAL IMPACTS

SDEIS Appendix F, Section 2 Mitigation Goals and Objectives, Page 16

Statement: "*This section provides an overview of effects for the key environmental resources affected by NISP, and a summary of mitigation approaches that were identified by Northern Water.*"

Comment: In violation of NEPA, the Corps has "failed entirely to consider an important aspect of the problem." *State Farm*, 463 U.S. at 43. The Corps cannot ignore visual impacts of the proposed action. Thus, the Corps must include in a revised or supplement to the SDEIS additional analyses of visual impacts and provide adequate mitigation measures to address the deficiencies described above.

9.5 AUGMENTATION PROGRAM AND MITIGATION

SDEIS Section 4.16.6, Unavoidable Adverse Impacts

Statement: "*The District's proposed mitigation will be reviewed by the Corps to determine whether unavoidable adverse impacts would remain with the implementation of the District's proposed mitigation.*"

SDEIS Appendix F, Section 2.1.2, Mitigation Approach

Statement: "*Glade Reservoir provides an opportunity for low-flow aquatic resources mitigation. […] Modification of diversion structures to allow fish migration and enhance channel characteristics would…benefit aquatic resources….*"

Comment: Fort Collins supports efforts to enhance winter base flows, which may provide a minor benefit to the fishery in Segment B. Based on the Poudre River Ecosystem Response Model, 20 to 30 cfs is an optimal base-flow regime for the sport fishery. (As noted elsewhere in these comments, it is not clear that Northern will be able to deliver the proposed augmentation flows due to water rights issues.)

Fort Collins supports efforts to modify intervening diversion structures to improve habitat characteristics. As noted elsewhere in these comments, the Conceptual Mitigation Plan proposes improvements to three structures to bypass flows. There are, however, a number of other structures that lack the infrastructure to bypass flows (See Operational Comments regarding SDEIS Section 7.3.5).

As noted elsewhere in these comments, Fort Collins has concluded that flushing flows of 2,500 to 3,500 cfs increase the likelihood that "multiple factors supporting reproduction of both trout and aquatic insects are…maintained over decadal and longer time scales." (See Fort Collins comments in Section 7 of these comments and the Poudre River Ecosystem Response Model). SDEIS Appendix F, however, does not include any flushing flows.

In general, the SDEIS does not establish that the current mitigation plan will adequately address the negative Poudre River recreation impacts; particularly those impacts to recreation caused by reduced peak flows. Fort Collins has concluded that it will not, based on the data presented. Furthermore, flat water recreation or other forms of recreation located at Glade Reservoir do not compensate for the loss of water-based recreation in Fort Collins because such flat water recreation is of a different nature than recreation on a dynamic, healthy river.

It is also unclear how the Corps derived the flatwater visitation values for the Glade Reservoir and whether these add to visitor numbers that would have already existed elsewhere or

simply shift visitation between lakes. If the latter, it is inappropriate to claim any net recreational or economic benefits.

The SDEIS must include avoidance, minimization, and mitigation measures that address flushing flows. The Corps must also require compensatory mitigation for the major loss of boating days on Segment B.

[Remainder of Page Left Blank Intentionally]

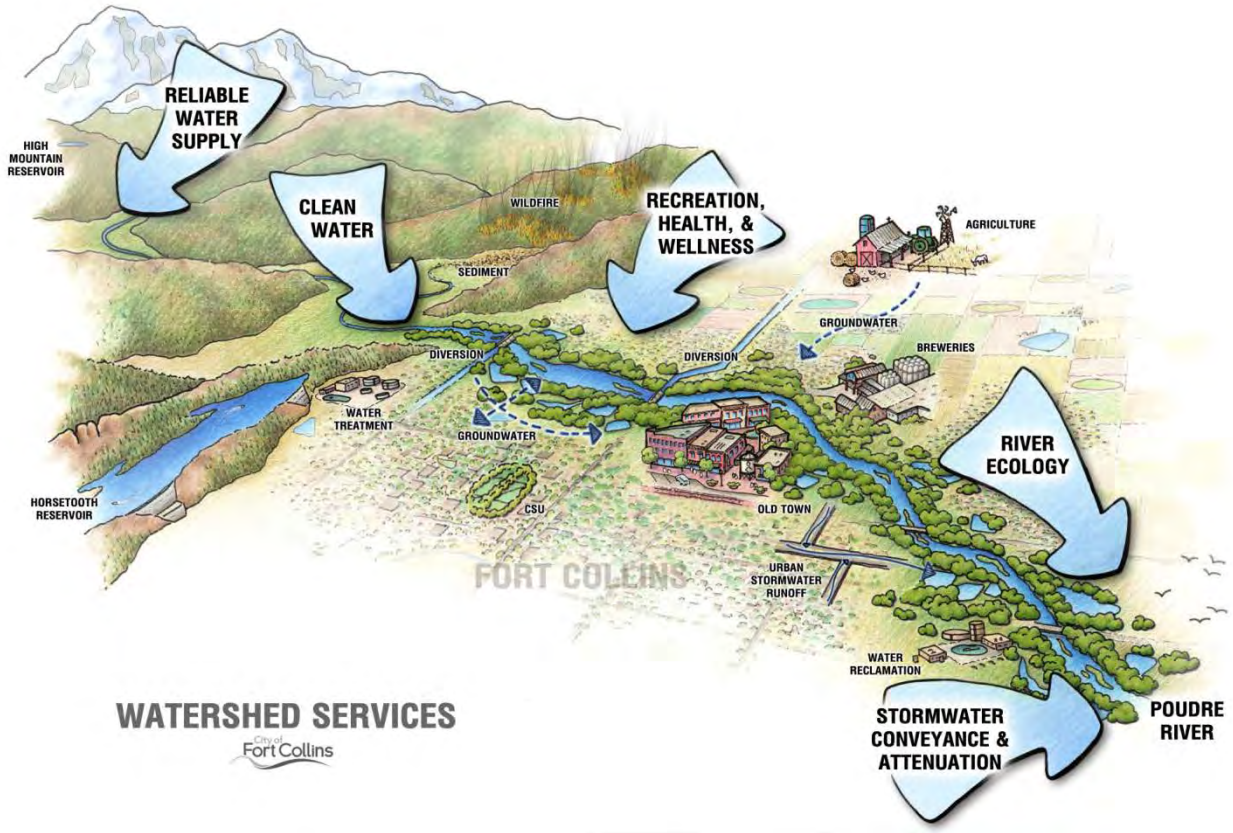
SECTION 10: BIOLOGICAL RESOURCES COMMENTS

Fort Collins has invested substantially in the Poudre River corridor through town, and thereby in its biological resources, which includes aquatics and fisheries, wetlands and riparian areas (including their ground water aspects), and wildlife. Fort Collins (including through its Natural Areas and Parks Departments and Stormwater Utility) owns and manages nearly 75% of the floodplain in town as undeveloped lands. The trout populations within Fort Collins are as high as some of the most productive areas for the river. *See* Fish Survey, Colorado Parks and Wildlife, Cache La Poudre Fish Survey and Management Information. These investments provide extensive recreation and educational opportunities, conservation of natural habitats and species, flood attenuation, pollutant filtration and serve as catchments for urban stormwater catchments (City of Fort Collins, 2011). A degradation of these resources, a likely outcome of NISP, would substantially and negatively affect these valued investments and assets. The SDEIS's analyses of wetlands and riparian areas raise various concerns as discussed in detail in the following subsections.

10.1 THE POUDRE RIVER IS NOT ON AN INEVITABLE DOWNWARD TRAJECTORY AS CLAIMED IN THE SDEIS, AND THE ECOLOGICAL RESPONSE MODEL AND RIVER HEALTH ASSESSMENT FRAMEWORK CAN BE USED AS TOOLS

Comment: Fort Collins has conducted various studies on the Poudre River designed to increase the understanding of current and potential future conditions. As the owner of water, wastewater, and stormwater utilities, Fort Collins is constantly conducting studies related to the functions of these enterprises. As a landowner, municipality, and steward of the land and water for current and future residents, Fort Collins has also sought to better understand the Poudre River beyond the scope of these vital utilities through conducting studies on other aspects of the river. Several of those studies are identified in and provided with these comments. In particular, studies have been designed to further understand site specific issues (such as land use in the floodplain), drivers (such as inundation of the riparian zone) and thresholds (such as sediment mobility flow thresholds) that influence the condition of ecological components and also to understand the system as an integrated sum of its parts.

The future of the Poudre River is of interest to Fort Collins not only for the intrinsic value of a healthy ecosystem, but also for the role a healthy ecosystem plays in the provision of other watershed services such as high quality drinking water, wildlife habitat, the basis of the aquatic ecosystem, recreation opportunities, and protection of public safety and infrastructure, all of which contribute to a healthy Fort Collins economy and livelihood. The condition of these watershed services has a direct financial impact on the City, as well as deeper impacts that are less easily quantified, though no less valuable.



The SDEIS inaccurately describes the Poudre River as having an ecosystem that has already passed a biological threshold and that is on a boundlessly declining trajectory. The SDEIS concludes that important ecological processes such as sediment mobility and support of riparian functions are not currently occurring and therefore additional reductions are "*predicted to reinforce or accelerate the well-established trajectory*" (SDEIS Section 4.9.9 Table 4-69) (emphasis added). Based on this proposition, the SDEIS concludes that any negative impacts from the proposed actions of NISP are minor or imperceptible, and not significant when considered against this supposed inevitable trajectory towards an impoverished system. However, neither NEPA nor the CWA allow agencies to disregard the impacts of proposed actions by assuming that environmental resources will be lost regardless.

Fort Collins disagrees with the notion espoused in the SDEIS that the Poudre River is on a trajectory of inevitable decline. Although many changes have occurred to the Poudre River over the past 150 years since the early days of water development, Fort Collins' perspective, supported by numerous observations and data, is that today's ecosystem still retains many functional elements that are key building blocks of a resilient and healthy system that continues to provide valued services. Moreover, as discussed in this Section 10, Fort Collins believes that a series of flawed analyses in the SDEIS underestimates the impacts of NISP, mischaracterizes the trajectory, and omits an evaluation of the aggregate impacts of the Project. As a consequence, the SDEIS incorrectly concludes that there will be minor or negligible impacts to the biological and watershed services and resources associated with the river.

The following reports and supporting analyses are submitted as evidence further substantiating the concern that the SDEIS mischaracterizes the trajectory.

The **Ecosystem Response Model** ("ERM") is a probability-based integrative ecosystem model developed to show likely changes and trends across various flow scenarios. The original report was produced in 2014 and provides the full project description http://www.fcgov.com/naturalareas/eco-response.php. With the release of the SDEIS and CTP hydrology, the ERM was rerun. New results are provided in the ERM Supplemental Report (City of Fort Collins, 2015). In preparing this work Fort Collins does not intend the ERM or its results to supplant the various in-depth studies undertaken as part of the SDEIS. Nevertheless, results of the ERM provide a meaningful holistic evaluation of the Poudre River ecosystem, an ecosystem which, contrary to conclusions made from various individualized studies in the SDEIS, maintains many key ecologic functions.

The **River Health Assessment Framework** ("Framework") was developed as a tool to clearly define the Fort Collins' vision of a healthy and resilient river through recommended ranges for system metrics (http://www.fcgov.com/naturalareas/riverhealth.php). As with the ERM, the Framework is not intended to supplant the various in-depth studies undertaken as part of the SDEIS. The Framework also sets forth a methodology for assessing and communicating about river conditions and functions. The Framework uses a scholastic A through F grading scale to grade different metrics, which represent various components of the river system. Grades of B and above signify a resilient component of the system. Grades of C identify at risk components, while grades of D and below represent impaired or vulnerable components. The closer any single metric gets to the C- to D+ threshold, the more at-risk it becomes.

Though each component receives a separate grade, these components work synergistically to support a more robust, functional ecosystem with greater resilience to future disturbances, stochastic events, and short-term or localized human-caused impacts. In other words, each metric contributes to an overall system that has good function, or conversely may be at greater risk. Therefore, a grade of a B or an A for one metric supports other metrics. Conversely, a grade of D or F would indicate impairment or imminent vulnerability which may have broad implications for whole system

Even though current conditions have not been fully assessed using this tool, much is known for various metrics through existing datasets and extensive working knowledge of the river. Preliminary evaluations indicate that current conditions generally range from grades of B to C, with a few metrics falling below a C. Given the expected response of the Poudre River to a decline in flows, and if flows are reduced by NISP as indicated in the SDEIS and discussed herein, a number of the metrics are expected to trend downward from their current condition. (Please see the Framework report for the best understanding of current conditions by river segment).

A few important themes emerge from the ERM and the Framework. The Poudre River will show a response to declines in peak flows in particular. Current flows still meet key sediment mobility thresholds which positively influence all aquatic life dependent on clean riverbeds. The preferred alternative decreases the return interval for these flows and will negatively affect overall channel structure, critical aquatic habitat and maintenance of channel capacity. The extent of all

riparian habitat types and ecological processes is directly correlated to peak flows. A measureable narrowing will occur across the riparian landscape.

The SDEIS must not consider the Poudre River as being on an inevitable downward trajectory, as discussed in this Section 10. *See State Farm*, 463 U.S. at 43 (explanation is not "satisfactory" if the "explanation for its decision . . . runs counter to the evidence before" the agency.). Fort Collins has identified that NISP poses significant challenges to the future condition of the Poudre River, with these concerns based, in part, on the ERM and the Framework. These tools also describe various opportunities for maintaining and improving the functions and processes that underpin the Poudre River's biological and healthy conditions. Thus, the ERM and the Framework can serve as effective guideposts and decision support tools as NISP and other consumptive projects are proposed and evaluated in the Poudre River basin.

10.2 COMMENTS REGARDING COTTONWOOD ESTABLISHMENT

10.2.1 Incorrect Assumption that Cottonwood Forests Are in Decline

SDEIS Summary S.6.4.2, Page S-32

Statement: "*flows that are no longer effective in establishing new stands of plains cottonwood*"

SDIES Summary S.7.6, Page S-45

Statement: "*The plains cottonwood woodlands along the Poudre River are on a trajectory of decline. Nonnative woody vegetation (e.g., green ash, Russian olive, and Siberian elm) are predicted to increase as a result of the current trajectory.*"

Comment: The summary for the analysis (Table 4-69) frequently relies on an assertion that the downward trajectory of cottonwood woodlands along the Poudre River will continue with or without Alternative 2. This argument has not been substantiated and directly contrasts evidence from Fort Collins' restoration successes and research projects (Shanahan, 2014, City of Fort Collins, 2015a, City of Fort Collins, 2015b). Moreover, the impacts identified in the SDEIS need to be quantified and not just described qualitatively. A direct response of narrowing (and reduction in the probability for cottonwood recruitment leading to age class distributions skewed toward older forests) is expected when peak flows are chronically reduced as well as a parallel reduction in the probability for cottonwood establishment (Nilsson and Svedmark, 2002). A data-based impacts analysis is possible through spatial comparison of flow events likely to support various ecological processes and habitat types.

Furthermore, it is in the City's interests to work towards restoring the system that supports the keystone native woody species. Forests dominated by native species, as compared to non-native species, are more adapted and therefore more resilient to natural disturbances on this type of system. A particularly unique situation may occur on the Poudre if we accept the premise that green ash will dominate the riparian forests (as described herein). With the arrival of the emerald ash borer to Colorado, the forests along the Poudre River are likely see a significant loss or degradation due to die off the ash (http://www.ext.colostate.edu/pubs/insect/eab_threat_urbanforests.pdf).

Rather than assume that the future decline of cottonwoods is inevitable, the impetus for Fort Collins' research and management has been to better understand the most effective actions for supporting self-sustaining cottonwood populations. Restoration efforts focused on topographical changes have proven highly productive for cottonwood establishment, as discussed in this Section 10. *See State Farm*, 463 U.S. at 43 (explanation is not "satisfactory" if the "explanation for its decision . . . runs counter to the evidence before" the agency.). In particular, the Fort Collins Natural Areas Department staff has found that when excessive shading and steep banks are restored, moderate flood events readily leads to extensive cottonwood recruitment. Hence, these types of efforts and observations made by Fort Collins contradict the SDEIS assertion of a baseline downward trajectory of cottonwood woodlands, indicating an incomplete disclosure of the baseline conditions in the SDEIS.

The analysis must be revised to include a quantitative (and spatial) analysis of the effects of all NISP alternatives on cottonwoods, and consider the role of floodplain topography as well as flows.

10.2.2 Inappropriate Analysis Based on Future Conditions

Wetlands and Riparian Resources Effects Report for the Mainstem of the Cache la Poudre River ("Resources Report"), Section 4.1.1, Trajectory for inundation of Riparian and Wetland Resources, Page 16

Statement: "*Part of the historical and future trajectory for the riparian and wetland resources of the Mainstem includes a continuation of the trend of less frequent inundation of wetland and riparian resources along the Mainstem*."

SDEIS Section 4.9.1.1, Resource Trajectory, Page 4-212

Statement: "*the trajectory of the wetland and riparian resources along the mainstem has been affected by historical and contemporary physical and hydrologic changes that have established a trajectory that is expected to continue under Current Conditions hydrology […] wetland and riparian plant communities along the mainstem will likely gradually shift to plant communities with species adapted to a drier environment and less tolerant of or dependent on flooding or shallow ground water levels…*"

Comment: The characterization of the trajectory of the riparian resource and phrase "trend of less frequent inundation" seems to indicate there will be ongoing hydrologic changes. Whereas other portions of the SDEIS perform analyses based on the current hydrologic conditions, the analysis of the riparian resource seems to be based on assumed future conditions, which are presumed to be worse than current conditions. This is not appropriate and downplays the effects of NISP. The analysis must be revised to base riparian analyses on current hydrologic conditions and not presumed future conditions.

10.2.3 Incorrect Conclusion That Current Flows Are the Primary Limitation

SDEIS Section 4.9.1.1, Resource Trajectory, Page 4-212

Statement: **"***The combination of flood flows that are no longer effective in establishing new stands of plains cottonwood, extensive stands of smooth brome and reed canarygrass that compete with cottonwood seedlings and nonnative woody vegetation that is establishing at rates equal to or greater than plains cottonwood,*

establish a trajectory for a future Poudre River riparian corridor that will likely be very different from the past and current riparian corridor."

Comment: As noted in comments below on the Resources Report, the primary cause for compositional changes to the riparian forest lies in physical constrictions of the river, banks, and floodplain. Nowhere in the SDEIS or supporting documents do data or ecologically-based logic demonstrate that current flows are a limitation. In contrast, as noted elsewhere in these comments, moderate flow events (such as the 5 year flow) can and do support cottonwood recruitment. *See State Farm*, 463 U.S. at 43. Further, intense, high flows cause mortality (through scour and burial) of brome and reed canarygrass in some years.

Furthermore, while this transition may be occurring on the landscape, it is arbitrary and incorrect to detach changes in flows due to NISP from this trajectory. The body of research on riparian ecology consistently relates flow regimes with trends in cottonwood populations. Flooding plays an essential role in the recruitment of cottonwood and a reduction in flooding invariably negatively affects cottonwood recruitment. Such will be the impacts from NISP and those impacts must be identified and analyzed. The analysis should be revised to reflect the impacts described above.

10.2.4 Incorrect Conclusions Regarding the Crossing of a Biologic Threshold

SDEIS Section 4.9.8, Unavoidable Adverse Impacts, Page 4-250

Statement: "*The 2012 Wetlands and Riparian Resources Baseline Report concluded that the mainstem had crossed a biologic threshold that limits the recruitment of plains cottonwood and is in the process of altering the composition of the riparian woodlands.*"

Comment: The data presented in the Resources Report does not support this conclusion, as discussed further below. In fact, the word "threshold" does not appear in the Resources Report. The analysis should be revised to remove references to a biologic threshold.

10.2.5 Incorrect Conclusions Regarding Green Ash

Resources Report, Section 5.3.1, Vegetation Trends, Nonnative Species, Page 26

Statement: "*Table 4. Ranking of Nonnative Species at each Poudre River Riparian Vegetation Study Site.*"

Comment: In the above-referenced table, the green ash species is recorded as a "4," being infrequently observed the lowest category for all six study sites. This data contradicts the oft-repeated conclusion throughout the SDEIS on the trajectory of this resource that the green ash species is likely going to replace cottonwoods and become the dominant species. By contrast, Table 5 (page 28) of the Resources Report reports young green ash (<2 dbh) receiving a ranking of #1 for Watson Lake and Martinez Park. The SDEIS Section 4.9.1, page, 4-212 suggests the upper two sites will continue to be dominated by narrowleaf cottonwood. These findings and inconsistent conclusions must be corrected.

10.2.6 Incorrect Conclusions Regarding Cottonwood Recruitment

Resources Report, Section 5.3.3 Size Class Distribution of Woody Vegetation, Page 29

Statement: "*Only three species, box elder, narrowleaf cottonwood, and plains cottonwood, were recorded in the two largest size classes that included individuals greater than 18 inches dbh. … At Martinez Park, although green ash occurred with the highest frequency, most of the individuals occurred in the smallest size class. … The Archery site had the fewest number of individuals compared to the other five sites. … Green ash was rarely recorded at the Archery site….*"

Comment: This discussion from the SDEIS is linked to the data in Table 6 (page 30) which shows, as the discussion suggests, only cottonwood, boxelder and crack willow species occur in the largest size classes. The data clearly shows that only cottonwoods demonstrate an inverse J-curve distribution of size classes. This type of distribution indicates ongoing recruitment and survival for cottonwoods. The issue with cottonwoods is that in these sites they are not demonstrating large recruitment events, but they are demonstrating continued modest recruitment.

The lack of older/larger green ash may indicate a transition is just beginning whereby green ash will become more dominant but it also may indicate green ash is not surviving past smaller/younger age classes. Ignoring this underlying uncertainty has led to incorrect conclusions**.** The analysis must be revised to properly analyze and acknowledge ongoing recruitment and survival for cottonwoods.

10.2.7 Inaccuracies Regarding Cottonwood Recruitment and Moderate Flow Events

Resources Report, Section 5.8.1, Establishment of Plains Cottonwood, Page 50

Statement: "*Cottonwood seedling recruitment is episodic and relatively rare even along free-flowing streams (Mahoney and Rood 1998)…. If river stages decline too rapidly, drought stress produces substantial seedling mortality (Scott et al. 1993). Along meandering rivers, successful establishment is characteristically associated with medium to large floods. Researchers have also determined that it is moderate and large flood events that directly enable cottonwood recruitment, whereas smaller flood events are often insufficient for cottonwood replenishment.*"

Comment: The use of the term "moderate flood event" is inconsistent and ill-defined throughout the report. It is used in Section 4.2.2 of the 2014 Technical Report (Riparian Effect) as follows: "the moderate flows of 580 to 1900 cfs do not currently inundate riparian and wetland areas with enough frequency to support or renew riparian areas and at most sites NISP will not substantially reduce the frequency of inundation by these moderate flows." The term "moderate flows" must be defined. The analysis must be revised to properly consider cottonwood recruitment and moderate flow events, as described above.

10.2.8 Disregard of Non-Major Recruitment Events

Resources Report, Section 5.8.2, Establishment of Plains Cottonwood Along the Poudre

Statement: "*An examination of cottonwood age classes in the Fort Collins reach of the Poudre River found the last major recruitment year was 1983 (Shanahan 2011a). The lack of natural lateral migration of the*

Poudre River has manifested a riparian forest that is no longer connected to the high flows and flooding with which the forest historically evolved (City of Fort Collins 2011)."

Comment: The SDEIS focuses on the last major recruitment event on the Poudre River in 1983. Fort Collins' experience suggests that armoring, and associated constraints on the channel and banks, as well as an altered species composition, most limits successful regeneration. The widespread recruitment observed at restoration sites following the 2014 spring flows (which peaked at ~6,000 cfs in late May) demonstrates the accuracy of this concept. This contradicts conclusions in the SDEIS, which state that the current flow regime is the major limiting factor.

The above image from McMurry Natural Area provides evidence of the potential for current flows to establish cottonwoods when the right physical conditions are present. 2015 seedlings are smaller (in the foreground) and 2014 saplings are seen on slightly higher ground (in the middle of the picture). *See State Farm*, 463 U.S. at 43 (explanation is not "satisfactory" if the "explanation for its decision . . . runs counter to the evidence before" the agency.). The analysis must be revised to address the role of moderate flood flows as well as topographical limitations to cottonwood recruitment.

10.3 COMMENTS REGARDING AQUATICS AND FISHERIES

10.3.1 Lack of Temperature Analysis

SDEIS Section 4.3.2.2, River Temperature

Statement: "*Thus, all NISP alternatives would be expected to increase stream temperatures at times in some reaches of the Poudre River. Additional detail on the conceptual understanding of the system and qualitative anticipated effects of NISP alternatives on stream temperature are provided in Hydros (2014a).*"

Comment: The SDEIS includes only a qualitative review of water temperature data with a subjective discussion of potential changes with NISP. The lack of a quantitative analysis of change in water temperature does not allow an evaluation of impacts to the aquatic species. The conclusions of "minor or moderate" impacts to aquatic resources and fisheries are not supported without quantification of the amount of change.

The Hydros 2014 Stream Temperature Report ("Hydros Report") is qualitative only with no quantification of change in temperature with the proposed alternatives, which GEI cites for water temperature impacts to fish and macro invertebrates. However, Hydros conducted dynamic water temperature modeling for the Windy Gap Firming Project EIS and CWA Section 401 certification. Miller Ecological also conducted dynamic water temperature modeling for the Moffat Collection System EIS and CWA Section 401 certification. No adequate basis is provided for the lack of such an analysis for NISP.

The change in Daily Maximum ("DM") and Mean Weekly Average Temperate ("MWAT") are derived from an hourly water temperature model. The CDPHE has protocols to determine the antidegradation analysis for the project from the modeled data. The anti-degradation calculation first calculates a Baseline Allowable Increment ("BAI"), which is 15% of the value between the baseline water temperature (current conditions) and the temperature threshold (either DM or MWAT). For example, if the baseline water temperature is 1.0 C away from the threshold then any change in water temperature greater than 0.15 C is considered a significant degradation. The analysis is complex to complete both the modeling and the antidegradation analysis.

The Baseline Allowable Increment ("BAI") for water temperature like other water quality constituents is 15%. The 15% translates to 0.15 C change for every 1.0 C lower than either the DM or MWAT threshold. The incremental change decreases the closer the water temperature gets to the threshold. If NISP results in an increase in water temperature, then the BAI may be smaller for Fort Collins when the Corps completes the analysis for the Halligan Project.

The lack of quantification of water temperature does not allow Fort Collins to meaningfully analyze NISP's impacts to aquatic resources in the Poudre River corridor. The change in water temperature is perceived to be small. However, even a small change in water temperature can result in a significant impact. The impact could be to the aquatic resources or to water treatment facilities in meeting discharge requirement, or both.

The full analysis of water temperature must be completed prior to release of the final EIS. Adequate review of the modeling approach and data sets should be allowed for participants in the Common Technical Platform. For example, Fort Collins should be provided with interim products to review the applicability and adequacy of the analyses. Mitigation for any approved alternative should include a requirement designed to offset any water temperature increase. The mitigation could be release of some amount of cold or cool water to offset the water temperature increase. The current mitigation is conceptual and does not include a sufficient detail and analyses to meet the applicable legal requirements.

10.3.2 Approach to Impacts on Aquatic Biological Resources

SDEIS Section 4.12, Aquatic Biological Resources

Statement: "*This section summarizes the predicted potential aquatic biological resources effects of the NISP alternatives. Fish, benthic invertebrate, periphyton, and aquatic plant communities and their habitat represent the components of the aquatic environment of interest for the project. […]*"

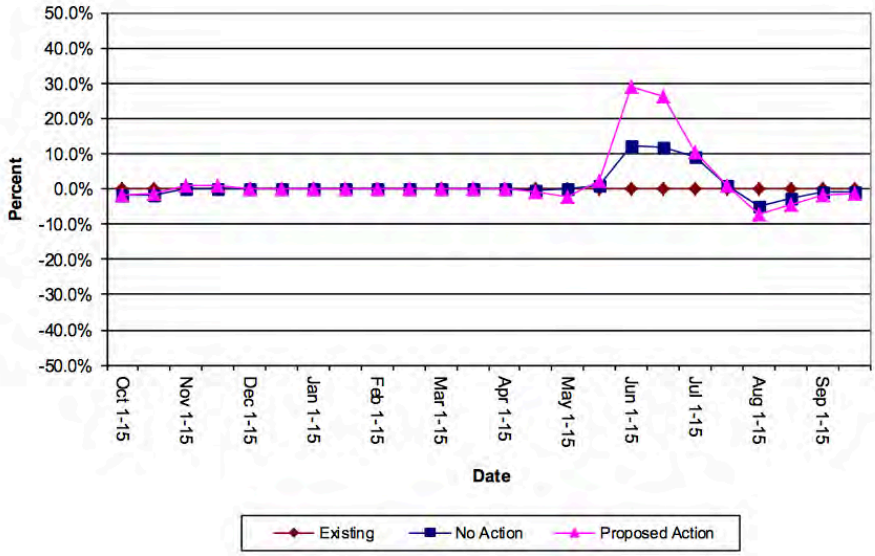
Comment: The conclusions for impacts of the NISP alternatives on aquatic habitat are based on an overly simplistic approach to calculation of changes to aquatic habitat. The change in fish habitat is based on synthetic graphs of 20%, median and 80% habitat constructed from a 25 year daily habitat time series. The annual graphs are then summarized into minimum, maximum and average habitat values. The percent change between the single average value derived from a 25 year daily simulation is used to determine the level of impact. This oversimplification of a detailed analysis does not allow the evaluation of inter- and intra-annual changes in habitat, which affect the fish species. (Annear et al. 2004). Further, there is no means to directly compare a habitat value with a specific discharge.

Page 4-314 of the SDEIS discusses changes in habitat with changes in flow. However, there is no means to verify any of the statements since computational data for habitat-flow time series is not presented in the supporting aquatic resource technical documents. For example, the recent EIS for the Windy Gap firming project included the basic habitat time series data by water year type as part of the technical supporting documentation (see following example Figure 3-101, Windy Gap Firming Project FEIS). The display of habitat by water year type or actual year allow the reader to make a direct comparison of habitat change between alternatives.

The aquatic habitat analysis up through the development of habitat versus flow determinations follows the standard approach used in instream flow studies. (Bovee et al. 1998, USGS 2001). The divergence from the standard approach is in the calculation of habitat over time. The use of a synthesized habitat values based on recurrence and then a single average value derived from the synthesized data masks the relationship of habitat over time. This approach does not allow a full analysis of impacts to the aquatic resources within Fort Collins, especially in the downtown corridor, which is highly valued.

The analyses and conclusions must be revised in these proceedings to address the deficiencies described above

Figure 3-101. Percent change in adult brown trout habitat from existing conditions on the Colorado River below Windy Gap for an average water year.



10.4 COMMENTS REGARDING ANALYSES OF WETLANDS AND RIPARIAN AREAS

10.4.1 Lack of Defined and Objective Standards

SDEIS Section 4.9.2, Methods, Page 4-213

Statement: "*Moderate effects would result in a clearly detectable change, with measureable effects. Moderate is used when beneficial or adverse effects would be noticeable, and the existing wetlands, riparian resources, or other waters would likely be lost. Moderate effects typically are long-term. Major effects would result in readily apparent effects with substantial consequences. Major is used when permanent impacts on large areas (10 acres) of wetlands, riparian areas, or other waters would occur.*"

SDEIS Section 4.12, Aquatic Biological Resources Methods

Statement: "*The overall impact was categorized as negligible, minor, moderate, or major according to professional judgment by taking into account the individual impacts to the components of the aquatic environment based on the magnitude of the changes, the risk of crossing an ecological threshold, the changes in habitat availability for other species and life stages in that segment, and the predicted changes to other relevant aspects such as water quality, temperature, channel geomorphology, sedimentation, and riparian vegetation.*"

Comment: The reliance on professional judgment without distinct metrics defined to determine the relative change between alternatives precludes replication of the conclusions in the SDEIS regarding of the level of effect. The subjective determination of impact makes it difficult to determine if any proposed mitigation is adequate to minimize the impact from an alternative. The above are

examples of the vague, qualitative language and standards used throughout the SDEIS. The SDEIS does not identify solid, scientific basis or objective standards for the proffered definitions.

For instance, regarding the statement from SDEIS Section 4.9.2 above, the permanent loss of wetlands is considered only a "moderate" effect despite its permanent nature. Also, the determination of "major" effect as one greater than 10 acres of permanent loss appears arbitrary without any reference to a reason for this delineation. In this arid region, riparian habitats and wetlands represent a small portion of the arid landscape and yet provide critical support for a majority of wildlife and increase overall richness in the region (Merritt et al. 2010, Naiman et al. 1993, Webb and Leake, 2006). Given the importance of these habitats, a reference or explanation for these definitions is required.

The analyses must clearly set forth all definitions and standards and the bases therefore. To the extent that this has not been completed in the SDEIS, the subject analyses must be revised accordingly.

10.4.2 Inconsistent Identification of Acres of Effected Wetlands

SDEIS Section 4.9.9, Impact Summary, Page 4-250

Statement: "Table 4-68 *Summary of unmitigated effects on wetlands and waters. 9 acres permanent impacts under Alternative 2.*"

2014 Riparian Effects Technical Report, Section 4.3.3, Page 41

Statement: "*The mapped potentially sensitive vegetation classes for Segments A through F are presented for varying distances from riverbanks in Table 14. For the entire length of the Mainstem there are about 220 acres of the potentially sensitive vegetation classes. Segment B is about 6 miles long and has about 10 acres of potentially sensitive vegetation within 100 feet of the river.*"

Comment: The SDEIS and its supporting reports appear to inconsistently quantify the number of effected wetlands, specifically for Alternative 2 in Segment B and with the result of reducing the number below the potentially-arbitrary threshold of 10 acres. This value is presented as 10 acres (a major effect) in the Resources Report and as 9 acres (a moderate effect for Segment B) in the SDEIS and summaries.

The analyses must correct or explain this discrepancy and the reasons therefore. The analyses must also apply all thresholds and standards in a consistent and objective manner. To the extent that this has not been completed in the SDEIS, the subject analyses must be revised accordingly.

10.4.3 Inconsistencies in the Riparian and Wetland Analyses

SDEIS Section 4.23, Summary, Page 4-415

Statement: "Table 4-109 *Wetlands from Poudre River flow changes (indirect effects).*"

Comment: Background on this analysis is provided in the Resources Report. On page 25 of that report, it states "the repeated stress of numerous years with prolonged groundwater declines could lead to loss of wetlands; however, most herbaceous wetlands would recover in subsequent years when the hydrologic support returns." If wetland hydrology is lost for a prolonged period of time, but returns occasionally (and infrequently such as during wet years or precipitation driven flood flows), this should be considered a permanent impact.

The summary table provided at the end of Section 4 of the SDEIS is the most succinct and comprehensive presentation of impacts of the alternatives in the SDEIS. However, this table omits the riparian areas despite having identified minor to moderate impacts throughout Table 4-69. Without explanation, this is arbitrary and suggests that the impacts from Alternative 2 are fewer and less severe that the underlying analyses indicate.

Table 4-69 also summarizes conclusions on river stage, alluvial groundwater, inundation, and other flood related functions analyses which are all linked to groundwater and soil saturation in the riparian zone. They should, at a minimum show common trends and scale of responses. However, Table 4-69 presents inconsistent and sometimes opposing results. For example, the results for Alternative 2 for "River Stage" are a moderate effect on Segment B whereas for "Alluvial Groundwater" a negligible effect is anticipated. Similarly, regarding "Inundation" there will be negligible impacts whereas for "Other Flood-Related Functions" (directly related to inundation) moderate effects are predicted. It is confusing for these pairs of analyses to show results that span from imperceptible to long term loss of resources.

Additionally, the last line on Table 4-109 describes "Other Flood-Related Functions." A determination of moderate effect is made for Alternative 2. However, the only reference to this conclusion comes from a single sentence on p. 4-218 (Indirect Effects Common to all Alternatives): "Reductions in inundation would potentially have some level of effect on these functions or the frequency at which these functions are provided." The conclusion lacks a basis. It is important as these processes support critical resilience factors such as pollutant filtration and floodwater attenuation. It msu be supported by something more than a single, conclusory sentence that is apparently without basis.

These contrasts and vacillations over the impacts to wetlands and riparian areas do not enable Fort Collins, other stakeholders, and ultimately, the Corps, to meaningfully analyze the impacts to these resources.

The analyses must consistently treat all alternatives. To the extent that this has not been completed in the SDEIS, the subject analyses should be revised accordingly. This confusion over the timing of impact of Alternative 2 persists throughout the Riparian and Wetland Conclusions, as discussed elsewhere in these comments.

10.4.4 Failure to Adequately Consider Long-Term Changes Resulting from NISP

Resources Report, Section 3.4, Wetland Functions, Page 12

Statement: "*Of the nine fundamental variables, only water source, water distribution, water outflow, chemical environment, and geomorphology are expected to potentially change in the short term for riverine wetlands as a result of the NISP alternatives*."

Comment: It is not clear why the above-referenced analysis only considers short-term changes. NISP would cause a permanent change in the flow regime of the Poudre River that will affect wetland conditions and related functions. Long-term changes to hydrology and vegetation variables, and the related changes in functions, must be fully analyzed.

10.5 COMMENTS REGARDING GROUND WATER ANALYSES AND ISSUES

10.5.1 Inaccurate Assumptions about Ground and Surface Water Interactions

SDEIS Section 3.5.3, Poudre River, Page 3-85

Statement: "*The river loses water to alluvial groundwater where the river crosses very permeable former channels and regains water when the river crosses former channels farther downstream. (ERO 2012b).*"

SDEIS Section 3.5.3.4, Poudre River Study Sites, Page 3-89

Statement: "*Water level observations at the six transects show a range of relationships between the alluvial ground water and river stage. […] In these areas, if alluvium receives recharge from a rising river stage, the alluvium discharge this water back to the river within a very short period.*"

SDEIS Section 4.5.1, Methods, Page 4-177

Statement: "*Using the largest predicted stage reduction at each study site for each of the action alternatives, and river stage-ground water relationships developed for each monitoring well, graphs were constructed with predicted reduction in depth to ground water as a function of distance from the river for the action alternatives (ERO 2013b).*"

Comment: The description of river losses on the Poudre River in the SDEIS oversimplifies such patterns and establishes inaccurate assumptions for the subsequent impact analysis of Fort Collins' wetlands and riparian resources.

The analysis disregards key aspects of the alluvial exchange processes, it should be revised, e.g., to consider:

- The alluvium throughout the river corridor is quite permeable, and alluvial recharge is more widespread and complex than flow through "former channels" implies.
- River gain-loss patterns are influenced by streambed heterogeneity, variations in streambank material, channel geometry, saturation, evapotranspiration, and local groundwater and surface water elevation. As a result, the volume of water recharging the alluvium and its residence time will vary depending on differences in hydraulic head between the river and surrounding aquifer (per Darcy's Law). These head differences are in turn influenced by

numerous local factors such as ditch diversions, supplemental recharge, etc. which vary on subreach and site-specific scales.

- Even brief transient recharge is important for ecosystem processes, such as nutrient processing, and should not be discounted.

10.5.2 Shortcomings in the Data Used for the Ground Water Analysis

SDEIS Section 4.5.1 Methods, Pages 4-176 to 4-177

Statement: "*As part of additional studies performed for the SDEIS, a hydrologic investigation of the mainstem of the Poudre River was conducted from 2009 through 2011. […] The 2012 Ground Water Report (ERO 2012b) provides details for the six transects that were established along the Poudre River, data collection methods, and discussion and interpretation of the results. […] Using the largest predicted stage reduction at each study site for each of the action alternatives, and river stage-ground water relationships developed for each monitoring well, graphs were constructed with predicted reduction in depth to ground water as a function of distance from the river for the action alternatives (ERO 2013b).*"

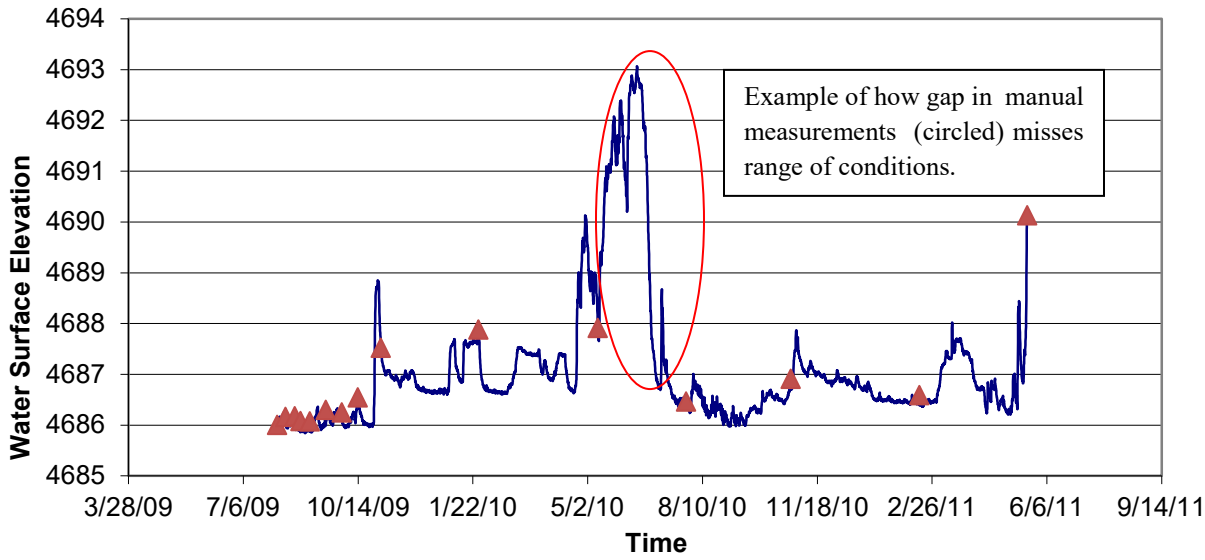
Comment: Data used to establish the river stage-ground water relationships appear not to be representative, complete, or consistently interpreted as described below.

As identified in Fort Collins' comments to the Draft Baseline Ground Water Technical Report in August 24, 2011, which are part of the administrative record in these proceedings, ground water wells at Lee Martinez Park may not be representative of the segment because they are located in areas that are supported by supplemental ground water recharge due to their proximity to a flooded gravel pit having a water surface that is maintained at an elevation about 10 feet higher than the river due to the inflow of "salvaged water." The SDEIS and the 2013 Ground Water Effects Analysis support the City's concerns from 2011. While it is true that upgradient groundwater recharge may occur in numerous other places along the river, the magnitude of these influences on the water table varies. For example, variation in groundwater levels is evident within the Martinez transect itself, where piezometers located at similar distances from the river but on opposite sides respond quite differently. During the EIS study, for example, the differences in reported ground water elevations for L3 and L4 – which are relatively equidistant and across the river from each other – was an average of 0.87 foot and ranged from 0.27 foot (9/16/09) up to 6.21 foot (5/11/09). These local variations in the aquifer make it questionable to apply relationships established based on distance from the river in one location to another location, even in the same segment.

The SDEIS is inconsistent by first stating that groundwater monitoring at the study sites should be considered "as a whole," but then eliminating data from two of the six transects because the observed measurements did not fit the anticipated patterns for distance from the river relationships. According to the Wetlands and Riparian Effects Technical Report, page 8, "Because a clear relationship of change in ground water levels and river stage with distance was not apparent at Eastman park and 59th Avenue, an average of the four other sites was calculated to estimate the percent change of ground water based on stage changes at various distances." The rationale for applying transect data from one location to another is not sufficiently justified, and if one-third of the study results do not fit within the hydrogeologic conceptual model and analysis method, it suggests the model and method need to be refined.

The datasets used to establish the river stage-ground water level relationships are incomplete because continuously recorded data from loggers were not available for all wells or river stage locations. Widely-spaced, manual readings (and weekly average readings) do not capture the full range of relationship between river and groundwater. This is an important consideration because Lee Martinez Park did not have a river logger, so the river stage-ground water relationship was based on sporadic manual readings that cannot accurately reflect the relationship. To demonstrate the type of data that can be missed see the figure below (Modified Figure 13 from the ground water technical report) which compares manual readings (red triangles) to continuous logger readings. The circled period of record demonstrates how the entire groundwater peak was missed by the manual readings in spring 2010.

Figure 13. 59th Street - Well 59-3



It is also unclear how accurate river stage-groundwater relationships could have been established for "each monitoring well," when half (14) of the 28 wells and two of the six surface water stations were not equipped with continuous data loggers. Additionally, for two of the reaches, piezometer data were not used and instead averages from the other four sites were applied, and by definition using an average will not show maximum effects.

Rather than discount or replace site-specific data with averages from other segments, river subreaches could be characterized based on hydromorphic classifications (e.g., based on similar geometry, boundaries, upgradient influences) and relationships could be developed and applied based on their classifications. Site-specific data could be used, at a minimum for comparison, with each pieziometer having its own water table fluctuation relationship, despite the fact it may not be linear.

SDEIS Section 4.9.4, Indirect Effects Common to Action Alternatives, Page 4-219

Statement: "*The effects of decline in river stage on alluvial ground water levels greater than about 100 ft from the river are predicted to be generally less than the 0.5 ft impact threshold.*"

SDEIS Section 4.5.7, Impact Summary, Page 4-187

Statement: "*As discussed above, reductions in alluvial ground water levels were used to predict resource effects and are addressed in those sections of the SDEIS. The predicted reductions to ground water levels in the alluvium would be similar for all action alternatives. Within 50 ft of the river, ground water level differences between the alternatives would be a maximum of about 0.5 ft. The difference in predicted reductions in ground water levels between alternatives would decrease as a function of distance from the river (4-59).*"

Comment: The basis for the statement in Section 4.9.4 is unclear. According to Figure 4-59, changes in depth to ground water greater than one foot were predicted at each of the graphed sites beyond the 100 foot distance from the river. Therefore, the 100 foot distance from the river appears to be unfounded, and groundwater impacts occur at further distances.

Furthermore, based on the data collection and analysis methods that were used, it is unknown if impacts greater than 0.5 foot and/or beyond 50 foot from the river may occur. The impact analysis using the distance from the river function does not address times and locations where the river influence extends further out due to factors such as river configuration and more permeable alluvial deposits. Impacts at greater than 100 feet from the river in some segments should be more fully evaluated.

10.5.3 Misinterpretation of Data

SDEIS Section 4.5.3.2, Poudre River Segments, Page 4-182

Statement: "*…The effect of these buried channels can be seen on Figure 4-59 where predicted ground water level reductions are out of character with distance from the river and neighboring monitoring wells.*"

Comment: The observed influence of the river at greater distance from the river is not "out of character" but rather reflects the character of many places along the river. The alluvium is very heterogeneous with permeable pockets of material, not just channels, known to occur throughout the deposits. It is not surprising for river influence to occur at greater distances from the river than the analysis expected, and it is not out of character. These observations demonstrate the limitations of assessing impacts to wetlands and riparian areas based on the distance from the river approach. This interpretation should be re-evaluated.

SDEIS 4.5.3.2.1 Poudre River Segments, Segment C, Page 4-183

Statement: *"Similar to Segment B, the reductions in ground water levels decrease in a relatively short distance from the river."*

Comment: The reduction in groundwater levels in this segment is not similar to Segment B, so this statement appears to under report the effects. At 200 feet from the river in Segment C, there is still a 1-ft decline in ground water for the three alternatives, which is twice the impact observed in Segment B at the same distance (where only 0.5 foot decline is observed, probably due in part to the upgradient recharge as previously discussed). This interpretation should be re-evaluated.

SDEIS Section 4.9.4, Indirect Effects Common to Action Alternatives, Page 4-219

Statement: "Table 4-70 in Section 4.9.9 summarizes the predicted depths to the alluvial ground water level for the action alternatives. None of the declines in groundwater levels within the cottonwood woodlands are predicted to be greater than 2.5 ft below the deepest annual water table depth during the growing season. Effects on the cottonwoods associated with declines in river stage of 2 feet or greater are predicted to be limited to periodic short-lived stresses because the estimated declines in alluvial ground water levels are predicted to occur infrequently (i.e. not predicted to be sustained) and are generally predicted to occur in May at the beginning of the growing season when soil moisture conditions are typically favorable for supporting cottonwoods without dependence on shallow ground water levels."

Comment: Impacts of ground water declines in riparian areas appear to be underestimated for multiple reasons. There appears to be insufficient basis to claim that the maximum declines will be limited to periodic short-lived stress. The frequency, duration, and impact of declines will be influenced by the change in the volume of water storage and availability in the riparian zone (e.g., which could be done using a daily water budget approach). There is no discussion of the effects of change in the volume of riparian water storage over time, e.g., to address impacts when there is already a groundwater deficit due to drought years or extended incremental declines in recharge. Reliance on May precipitation and soil moisture to offset impacts is inherently uncertain and should not be justification for discounting negative effects. Further, May precipitation already affects the system and is not a new measure to offset NISP diversions. The ecological significance of some key exchange processes between rivers and ground water are not evaluated. For example, saturated soils during alluvial recharge play an important role in nitrogen processing (and can provide a nitrogen pulse at a critical time in the growing season) when e.g., anaerobic conditions trigger microbial denitrification. This interpretation should be re-evaluated.

10.6 COMMENTS REGARDING ANALYSES OF POUDRE RIVER WETLANDS

10.6.1 Inappropriate Assumption of Changes in River Stage of 0.5 Feet or Less

SDEIS Section 4.5.1 Methods, Pages 4-176 to 4-177

Statement: "*This approach was taken because most of the reductions in river stage are predicted to be 0.5 ft or less (Appendix A of the 2014 Wetland and Riparian Effects Report) and therefore would have had only minor reductions on associated alluvial groundwater levels. A maximum effect scenario was of interest because alluvial ground water levels can influence cottonwood woodlands and reductions in ground water levels below the annual water table low (Section 4.3.1 of the 2014 Wetland and Riparian Effects Report.)*"

Resources Report, Section 4.2.2, River Stage, Page 21

Statement: "*Changes of 0.5 foot or greater in river stage during the growing season was selected as the threshold for potential impacts because herbaceous wetlands would likely start being affected by groundwater declines of greater than 0.5 foot. Declines in ground water elevations during the growing season of less than 0.5 foot are well within the range of normal fluctuations that are already occurring as observed in monitoring wells at the riparian vegetation study sites (ERO 2012a).*"

SDEIS Section 4.9.2.1.1, Impact Thresholds, Poudre River Stage, Page 4-214

Statement: "*....were reviewed for changes in river stage of 0.5 foot or greater during the growing season... A threshold of 0.5-foot decline in river stage was used to determine potential effects on herbaceous and shrub wetlands. Herbaceous wetlands are potentially the most sensitive communities to declines in alluvial ground*

water levels. The Corps' technical standard for wetland hydrology is that the wetland site is inundated (flooded or ponded) or the water table is 12 inches or less below the soil surface for 14 or more consecutive days during the growing season at a minimum frequency of 5 years in 10 (50% or higher probability) (Corps 2005). Assuming an average midpoint of 0.5 foot for ground water levels for wetlands, a decline of less than 0.5 foot in ground water levels would still meet the threshold for wetland hydrology."

Comment: Using the 0.5 foot decline combined with a mid-point of 0.5 foot ground water level below ground surface is an inappropriate threshold for assessing wetland impacts for a maximum effects analysis, and the basis for this approach is neither justified nor logical. A wetland with an initial water table near the 1 ft depth would be impacted by declines of less than 0.5 ft. If, for example, a wetland has a water table depth of 11.9," then a decline of less than 0.2 foot could cause a shift from wetland to non-wetland hydrology. Therefore, a maximum effects analysis should evaluate impacts from a lower starting elevation in herbaceous wetland areas (especially based on the assumption that in a dry year the water table will likely be starting out at a worst case scenario).

Section 4.2.2 is the first location in the SDEIS that this threshold is identified. However, no basis for this threshold is provided; and such a threshold is not a convention in wetland science. The response of vegetation and soil microbiota to changes in ground water levels and fluctuations is different in different textured soils, on sites with stable versus variable water tables, and on plants with different root morphologies and physiological responses. The SDEIS ignores the context and range of possible responses for the Poudre River. The statement that the 0.5 foot of fluctuation and decline falls within normal ranges of fluctuations is not relevant since the alternatives do not affect these short-term fluctuations, but rather, they compound them and cause a long-term decline of average ground water depths amidst ongoing smaller fluctuations. This will cause significant and long-term changes in wetland hydrology, which will cause changes in vegetation composition and structure, soil microbial processes, and habitat quality.

The assumption that river stage declines exceeding 0.5 foot for greater than 10% of the period of record may adversely impact wetlands is flawed as discussed above. It would be more realistic and less arbitrary to base the approximate average depth of groundwater for wetlands on the type of wetland plant community present along the corridor. For example, *Typha* (cattail) and *Scirpus* (bulrush) would have groundwater at approximately ground level (fully saturated soil column and possibly standing water), a community dominated by *Carex nebrascensis* would have groundwater at approximately six inches to one foot, and a *Salix exigua* dominated system may have ground water at depths of greater than one foot (Henszey et. al., 2004). Thus, certain communities are more vulnerable to changes in depth to ground water and seasonal fluctuations in ground water.

Any wetland community with the average groundwater table deeper than six inches may no longer be able to support wetland plant communities and wetland functions with a reduction in groundwater less than 0.5 foot. For example, cattail marshes would likely see a shift in species composition whereas drier wetlands like those dominated by *Carex nebrascensis* may be completely lost (Henszey et. al., 2004).

The analysis should be revised and corrected so as not to include the assumption of uniform response to altered wetland hydrology as discussed above. If no alternate approach is applied,

examples of other federal permits or peer reviewed research that has used this approach should be provided to help the reader understand the basis for the conclusions reached.

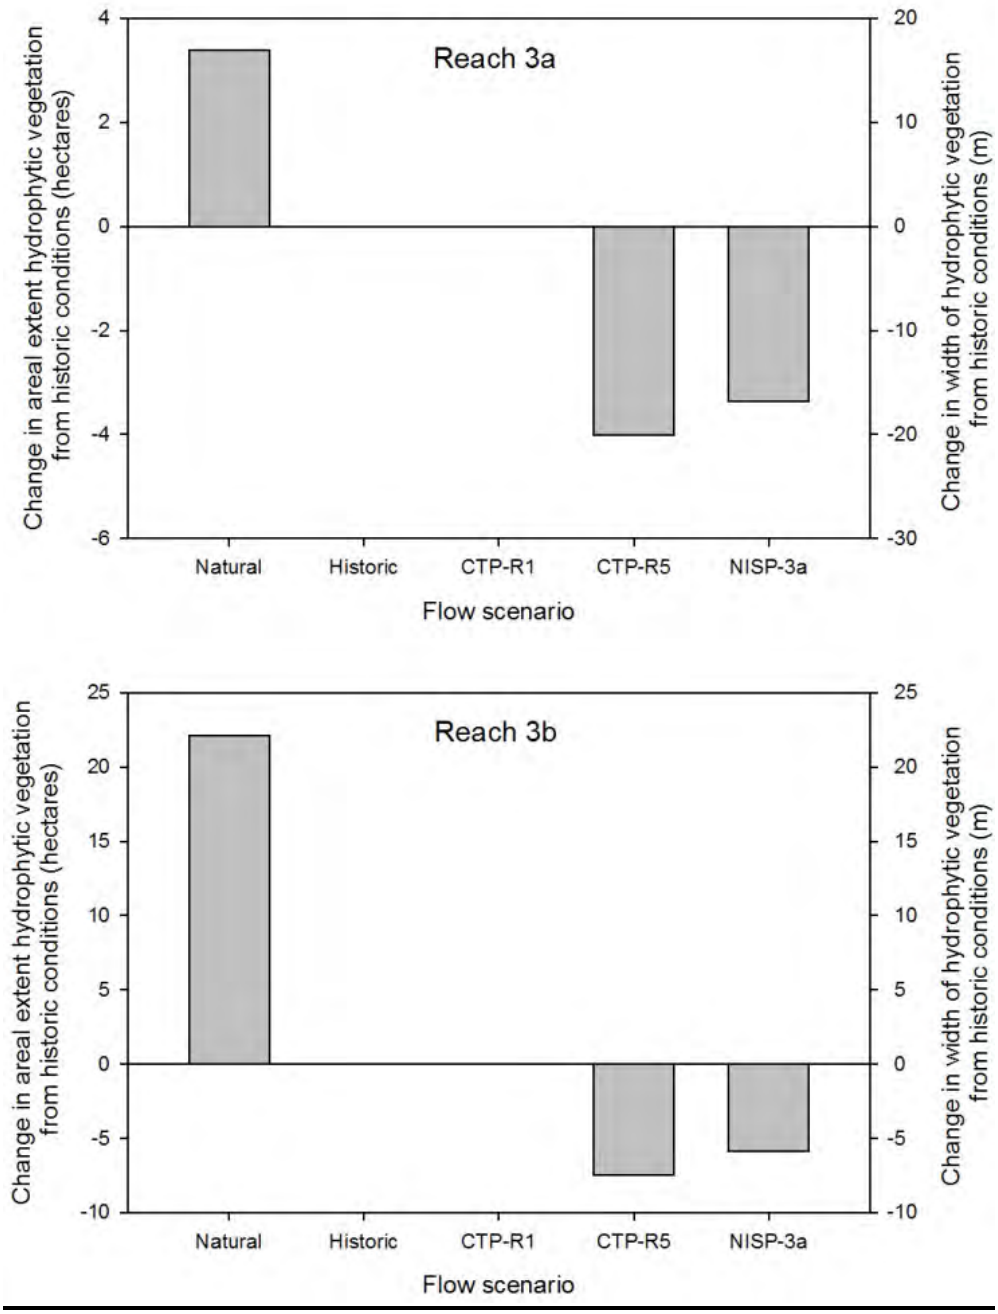
10.6.2 Inappropriate Assumption of Changes of a Duration of 10% or Less

SDEIS Section 4.9.2.1.1, Impact Thresholds, Poudre River Stage, Page 4-214

Statement: "*At 10% or less the effect would be negligible because 10% represents an average of 2 weeks during each year of the growing season and the Corps' technical standard for wetland hydrology is that the wetland is inundated…for 14 or more consecutive days…..*"

Comment: If a site currently has wetland hydrology for two weeks per year (thereby just marginally meeting the USCOE standard for jurisdicaitonal wetland), then a shift of less than 10% of the period (such as one week per year) will cause the site to be inundated less than the two-week criteria in the USCOE definition. Altering hydrology, by definition, will indeed cause changes in the inundation duration. This is a cause and effect linkage that cannot be contested. The changes will effect wetlands acorss the entire gradient, but more so for those wetlands just inside the two week of inundation criteria.Such an averaging approach misses a considerable area of wetlands that will be affected and results in an underestimation of impacts. Hydrology is what distinguishes wetlands and riparian areas from adjacent uplands. The effects of altered flows well established in the literature (e.g., Merritt et al. 2010). Reduced peak flow, and reductions in inundation duration will cause narrowing and decreased extent of riparian areas and areal loss of wetlands.

Further, Fort Collins has run the CTP hydrology through its ERM vegetation model and has made the following findings. (Please see Appendix B5 Riparian Vegetation of the Poudre River Ecosystem Response Model for methods.) The results of this modeling are shown in the following graphic. The graphic illustrates the expected reduction in the width of hydrophytic vegetation in two reaches of the river from about the Larimer and Weld diversion to the Lake Canal in Martinez Park. Clearly the preferred alternative would have substantial long-term impacts to this band of vegetation. The analysis should be revised to not include the subject assumption as discussed above.



10.6.3 Inappropriate Assumption Regarding a Shift in Wetland Vegetation

SDEIS Section 4.9.2.1.1, Impact Thresholds, Poudre River Stage, Page 4-215

Statement: "*Stage declines of this magnitude during the growing season are predicted to results in a shift in species at wetlands dominated by obligate wetland species (i.e. cattail and threesquare bulrush) to those that tolerate greater fluctuations in river stage such as reed canarygrass. Since most wetlands along the banks of*

the mainstem are dominated by reed canarygrass and sandbar willow, two species that can tolerate greater range of groundwater levels effects are predicted to be minor and likely not perceptible along Segment B."

Comment: The overall basis of the wetlands analyses lies in whether any given wetland is going to shift from a wetland supporting hydrology that meets the definition of a wetland given the Corps' standards. The argument in the SDEIS shifts here, as cited above, to explain any potential impact to focus on species. However, this shift in focus does not change the fact that the subject wetlands will be lost as a result of NISP. Further, shifts in hydrology that favor generalist and stress tolerant species like reed canary grass is undesirable as this is a non native species that is persistent and competes for resources and space with desirable native riparian species.

Further, the statements made about shifts in species are based upon speculation rather than data and information. The SDEIS cites no analyses, no species distribution modeling, or other objective assessment to support the statements. There has been no consideration of context. For instance, species distributions might shift toward the channel. No evidence is provided to support the statement that most wetlands are reed canarygrass and sandbar willow.

The analysis should not include the above statements unless they are supported by an analysis, modeling, or other objective assessment. To the extent that this is not completed, such statements should not be included in the analysis.

10.6.4 Failure to Consider Permanent Shift in Poudre River Flows

Resources Report, Section 4.2.2, Stage Effects on Herbaceous and Shrub Wetlands, Page 24

Statement: "*Many types of wetlands in the West experience periods of drought and water stress each growing season but are resilient when supportive hydrologic conditions return. The repeated stress of numerous consecutive years with prolonged ground water declines could lead to the loss of wetlands; however, most herbaceous wetlands would recover in subsequent years when the hydrologic support returns.*"

Comment: The preferred alternative causes an absolute shift (decline) in groundwater levels. Even if wetlands in the western United States experience periods of drought and could recover, there is a quantifiable change that would occur under the preferred alternative. This explanation seems to be excusing the impacts rather than identifying them. A longer period of drought to a wetland can lead to a reduction in wetland condition (loss of functions, shifts in species composition) and/or a change or loss of the wetland plant species (often resulting in noxious weed invasion) Occasional return of the hydrology does not enable the plants to spontaneously return and favors non-native, weedy, ruderal plant species over native, perennial species.

The analysis should be based on the correct assumption that the changes to the Poudre River flow regime from NISP are permanent, and use this information to accurately describe and analyze wetland impacts. The analyses and interpretations should be revised accordingly.

10.6.5 Inappropriate Reliance on CDOW Mapping

Resources Report, Section 5, Existing Conditions Methods, Page 17

Statement: "*About 53 percent of the CDOW mapping within the area defined as the riparian corridor was field reviewed from publicly accessible sites or by remote sensing, and inaccuracies were changed to the appropriate category. Of the areas reviewed, about 49 percent of the CDOW-mapped areas were changed to another category.*"

Comment: The analysis and conclusions depends on the CDOW riparian mapping dataset. The fact that field verification of this data set reports only 51% accuracy is of significant concern and undermines its use in the SDEIS and supporting reports. This is not a scientifically defensible level of confidence. Furthermore, the minimum mapping unit for this methodology is 0.5 acre which would indicate small patches of wetlands, as expected in northern Colorado, may be missed or mischaracterized.

In 2011/2012 the Environment Protection Agency and Fort Collins provided comments on the initial draft of this technical report. Both sets of comments expressed concern regarding the high level of inaccuracy and uncertainty found during field review. The other option suggested was to rely instead on the U.S. Fish and Wildlife National Wetlands Inventory ("NWI") mapping data set.

The Corps responded that the CDOW mapping "will be used to describe the general extent, distribution, and composition of riparian vegetation along the mainstem of the Poudre River." Instead, the CDOW mapping seems to be the source of data for quantifying potentially impacted wetlands along the Poudre River. The NWI dataset recently completed along the Poudre River is the best data available for the subject wetlands. Additionally, Fort Collins Natural Areas has ongoing updated habitat mapping for restoration planning

10.6.6 Failure to Identify the Data Source for the Acres of Wetlands Impacted

Resources Report, Section 3, Methods, Page 4

Statement: "*Mapping of the vegetation was conducted on two levels: detailed mapping at the six riparian vegetation study sites …and broader vegetation mapping along the Mainstem from Colorado Parks and Wildlife…to describe general habitat types along the Mainstem*"

Comment: The purpose of the above-identified analysis is to provide a prediction of the acreage of wetlands impacted. It is unclear which data source was used to extrapolate the final conclusions of the acres of wetlands impacted. Indirectly, it seems the Colorado Department of Wildlife ("CDOW") mapping project was the source. However, this is not expressly stated anywhere in the SDEIS or the technical reports. Furthermore, as noted above, Fort Collins requested the GIS files for wetlands and riparian areas impacted for all alternatives from the Corps. The dataset provided by the Corps includes no wetland polygons along the Poudre River adding to the confusion.

The analysis should clearly and expressly identify the data source and analysis used to identify the acres of wetlands impacted by NISP. The analysis should be revised to use the NWI dataset.

10.7 COMMENTS REGARDING EFFECTS TO RIPARIAN HABITATS AND ECOLOGICAL PROCESSES

10.7.1 *Inappropriate Application of the Definition of Wetlands to Cottonwood Woodlands*

SDEIS Section 4.9.2.1.3, Inundation, Page 4-216

Statement: "*For the purposes of the effects analysis, cottonwood woodland sites predicted to be inundated in at least 13 years (half of the years of the period of record) under Current Conditions were assumed to receive some amount of hydrological support from inundation based on the Corps' technical standard for wetland hydrology that the site is inundated (flooded or ponded) or the water table is 12 inches or less below the soil surface for 14 or more consecutive days during the growing season at a minimum frequency of 5 years in 10 (>50% probability) (Corps 2005).*"

Comment: The application of Corps definition of wetland hydrology to analysis of impacts to riparian habitats (non-wetlands) is incorrect and inappropriate. No explanation is provided in the SDEIS for the use of wetlands hydrology in this context. The impact assessment methodology and analyses should be revised to more accurately reflect the hydrology of riparian woodlands, as discussed above.

10.7.2 Inappropriate Exclusion of Certain Riparian Forests

SDEIS Section 4.9.2.1.2, Alluvial Groundwater, Page 4-220

Statement: "*Inundation has the potential to provide supportive hydrology for wetland and riparian vegetation; however, inundation of many of the locations within the Poudre River study sites under Current Conditions occurs infrequently. […] For all action alternatives, the riparian and wetland locations inundated in more than half of the years under Current Conditions hydrology, and thus potentially more dependent on frequent inundation, are not predicted to have a substantial decrease in the number of years in which inundation occurs.*"

Comment: Periodic inundation is precisely what makes a riparian forest unique from an upland forest and other types of wetted habitats. (Naiman and Decamps, 1997). To suggest that sites that receive inundation less than 50% of the years will not experience an effect underestimates the extent of important, functioning riparian areas.

For those sites that are inundated "frequently," which would more accurately be referred to as wetlands, a significant reduction in peak flows caused by Alternative 2 would also be expected to cause a shift (narrowing) of riparian vegetation on the landscape. Table 4-71 indicates 8 data points were used to assess a 2,500 acre study area. This is an insufficient sample size for extrapolating such a conclusion. The SDEIS does not address this result. The analysis should be revised to include all riparian forests, as described above.

10.7.3 Incorrect Conclusions of Impacts to Riparian Forests

SDEIS Section 4.9.5.3.3, Preferred Alternative, Inundation, Page 4-229

Statement: "*Segment B. The plains cottonwood woodland locations within the Martinez Park study site, representative of Segment B, have minimum inundation flows of about 2,000 to 3,200 cfs (Table 4-71). Under Current Conditions, these locations would be inundated in about 4 to 11 years of the period of record. The*

number of years in which inundation would occur is predicted to be reduced by 1 to 5 years at these locations. None of these locations would be inundated in more than half of the years of the period of record under Current Conditions. Under Alternative 2, the estimated reduction in inundation is predicted to have a negligible effect on cottonwood woodlands in Segment B because under Current Conditions, the cottonwood woodlands are not inundated with enough frequency to provide consistent hydrologic support."

Comment: For those sites that are inundated "frequently," a significant reduction in peak flows a caused by Alternative 2 would also be expected to cause a shift (narrowing) on the landscape and all the complex functions and vegetation types supported by the peak flows. (City of Fort Collins, 2015a, City of Fort Collins, 2015b, Shanahan et al., 2014). In contrast to this expected result, all narratives related to this inundation analysis for Segment B conclude the effects will be negligible. An example in central Fort Collins: The quote above for the impacts of Alternative 2 references Table 4-71. This table shows three points (LMT2.1-3) will have reduced frequencies of inundation from 42% of the years to 23% of the years. This will have an impact on the probabilities for many of the aforementioned processes to occur. Please see the 5 year flow -analysis (please refer to Section 10.7.6) and the plant guilds analysis (presented in Section 10.6.2) as evidence substantiating the importance of "infrequent" flows and the likely narrowing of all processes and habitat types reliant on moderate flows. The analysis should be revised to include all riparian forests, as described above.

10.7.4 Incorrect Conclusions Regarding Impacts of Recent Flooding on Riparian Forests

SDEIS Section 4.9.4, Indirect Effects Common to Action Alternatives, Page 4-217

Statement: "*Flooding on the Poudre River mainstem in 2010, 2011, and 2013 provided the opportunity to review how flood flows and inundation affect wetland and riparian resources. Post-flood reviews of the mainstem determined that most of the vegetation and riverbanks of the reaches reviewed appeared to be unaffected by the floods. […] There were no observable effects on vegetation from the inundation outside of the active channel or stream banks other than the flattening of herbaceous vegetation and the accumulation and piling of woody debris. […]*

"*Flows of this magnitude did not create substantial areas of either newly deposited sediments or eroded areas beyond the active channel and riverbanks that could provide potential suitable substrate for colonization by riparian vegetation. The floods in early June of 2010 and 2011 occurred during the normal time for peak flows that can facilitate the establishment of new cottonwood stands. Very few areas of post-flood cottonwood seedlings were observed and the few areas of cottonwood seedlings that were observed occurred within and adjacent to the active channel where the cottonwood seedlings are vulnerable to inundation, channel erosion, and aggradation.*"

Comment: Fort Collins Natural Areas Department staff's observations contradict the above statements presented in the SDEIS. For example, Sterling, Homestead, and McMurry Natural Areas have all experienced substantial deposition of fine-grained materials in much of the riparian habitat as a result of high flow events between 2010 and 2014. Furthermore, not all floodplain functions associated with inundation are readily observable and the observations from a sample of sites and years should not overrule well established and accepted riparian scientific principles. Even the SDEIS outlines the processes known to occur with inundation, yet the narrative uses field review exclusively for ignoring these readily acknowledged ecological processes (See SDEIS Section 4.9.4).

In areas undergoing restoration where shading and thatch is not a limitation, extensive and significant establishment of new cohorts of native woody vegetation is occurring regularly and in direct response to flood flows. These areas include Sterling, McMurry, and Homestead Natural Areas. The following three photos show natural establishment and recruitment of native vegetation (specifically cottonwood and coyote willow) following recent high flow years at the McMurry Natural Area along the Poudre River. Following the wetter springs of the past few years (2010 through 2014), Fort Collins Natural Areas Department staff has observed an increase in several uncommon and desirable plants. For example, clammyweed (*Polanisia dodecandra*) was established at Springer Natural Area, more goldensmoke (*Corydalis curvisiliqua subsp. occidentalis*) and an increase in violas, which support rare butterflies have also been observed in response to the wet years. At the same time dieback of smooth brome close the river's edge and generally an overall robust growth for all riparian vegetation was observed each of the wet years that have occurred between 2010 and 2015.

Another high prolonged flow year occurred in the spring of 2014. The previous two photos show observations by Fort Collins Natural Areas Department staff from the air in June, 2014. The first photo above shows the Sterling Natural Area and the second photo shows the McMurry Natural Area. Each identify depositional zones (pockets of fine material seen throughout the riparian areas), with the red circles identifying areas of significant fine sediment movement and deposition.

Inundation even for brief periods drives numerous functions that distinguish riparian habitat from upland terrestrial habitats. Some of the ecological and hydrological functions and processes can be difficult to observe and the observations from a sample of sites and years should not overrule well established riparian processes. Even the SDEIS outlines the processes known to occur with inundation yet the narrative uses field review exclusively ignoring the readily acknowledged ecological processes (See SDEIS Section 4.9.4).

The analysis should be revised to include the observations described above and to include a more in-depth analysis of impacts to the other floodplain processes associated with inundation.

10.7.5 Incorrect Conclusions Regarding the Response of Cottonwoods to the Diversion of Peak Flows

Resources Report, Section 4.3.1 Changes in Ground Water Levels for Cottonwood Woodlands, Page 35-38

Statement: "*Scott et al. (1999) noted that over a three-year period in medium-grained alluvial sands, sustained declines in the water table of greater than 3.1 feet resulted in 88 percent mortality of plains cottonwood. […]*

"*Effects to the cottonwoods associated with declines in river stage of 2 feet or greater are predicted to be limited to periodic short-lived stresses because these estimated declines in alluvial ground water levels are predicted to occur infrequently (i.e., not predicted to be sustained) and are generally predicted to occur in May*

at the beginning of the growing season. […] Most of the declines in ground water levels are predicted to occur in May when soil moisture conditions are typically favorable for supporting cottonwoods without dependence on shallow ground water levels. May in Fort Collins is typically the wettest month of the growing season with an average of 2.74 inches of precipitation (18 percent of the annual average) […] The combinations of relatively high precipitation and low temperatures at the beginning of the growing season provide soil moisture levels that could support cottonwoods without shallow ground levels compared to the rest of the growing season […] Some or all of the following effects may occur infrequently to cottonwoods […] when ground water levels temporarily decline below the estimated deepest annual water table depth of 6.85 feet for the cottonwood woodlands:

- *Delayed leaf out (lengthened dormancy at beginning of growing season)*
- *Yellowing and loss (abscission) of leaves*
- *Reduced branch growth*
- *Branch die-back*

"*Effects from the 1-2 ft stage declines and subsequent ground water level declines are predicted to be negligible.*"

Comment: The SDEIS states that Scott et al. (1999) concludes that a sustained decline in ground water levels of 3.1 feet results in 88% cottonwood mortality whereas the declines as a result of NISP can be as much as 2.5 feet and equate to no mortality, only "short-lived stresses." This conclusion is not valid.

This conclusion is explained by saying that "most" of the declines would be in the wettest month, May. However, there is no evidence to suggest that reducing the peak flow would have no adverse effect on cottonwood woodlands. It is true that cottonwood trees are more vulnerable to water stress when temperatures are higher, when the canopy if fully leaved-out, and when less of the root system is in contact with the water table, all of which occur late in the growing season. Depending on position in the riparian zone, trees positioned at higher and drier sites will be more vulnerable to a 2.5 foot decline in peak streamflow than those nearer to the river and at a lower elevation. The vegetation is distributed along a gradient; the gradient is driven by the hydroperiod, inundation frequency, and depth to groundwater (as well as variability in these factors). Reducing the peak flow by diverting large volumes of water in the spring will have an effect on riparian vegetation. (Poff et al., 1997). Unequivocal statements about the cottonwood forests responding in a unified and single way to flows result in incorrect and arbitrary conclusions. The analysis should be revised to more accurately reflect the effects of the removal of peak flows, as described above.

10.7.6 Failure to Analyze Ecological Services

Resources Report, Section 5.8.9, Other Ecological Functions Associated with Flooding

Statement: "[T]*he degree to which the ecological services are provided vary with frequency, duration, and extent of flooding and are not discussed in this technical report because they have not been the focus of scoping or comments on the NISP DEIS and can vary greatly from site to site.*"

Comment: The evaluation of environmental impacts includes any changes to the natural environment as a result of the Project. The reduction of peak flows in the Poudre River will diminish the provision of valued ecological services. The statement in the SDEIS that these processes can vary greatly from site to site is precisely why it is important to analyze them. SDEIS

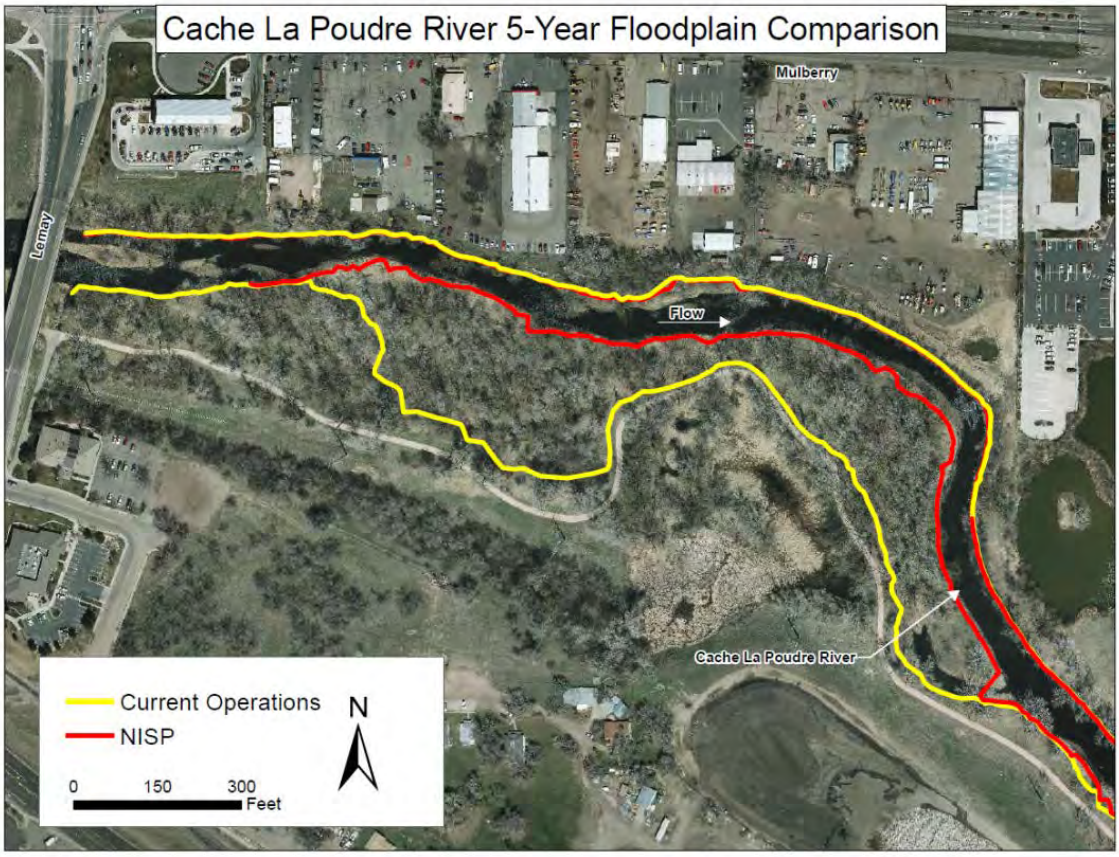
Section 4.9.4 describes this topic well and illustrates how ecological services are fundamentally important to river and riparian habitat dynamics. Understanding and disclosing how these ecological services would be affected are important aspects of the this NEPA analysis.

The areas inundated with a frequency at or greater than 20% of the time (the 5 year floodplain) could be considered as a possible surrogate for understanding changes to these services. The 5 year flow was used in both the RHAF and ERM Supplemental Report as an indicator of the positive relationship between important functions of the riparian forest and river-floodplain connectivity to moderate flows.

Fort Collins and its consultants calculated the 5 year flow at the USGS gage at the Lincoln St. gage using methods described in USGS bulletin 17b for historic, current conditions and Alternative 2 flow scenarios (see ERM Supplemental Report, Current Conditions and Alternative 2and USGS, 1982). Respectively this flow is 3,486, 3,018, and 2,366 cfs. According to these flow values, this "moderate flow" appears within range of flows most affected by the preferred alternative.

	Historic (3,486 cfs)	Run 1 Current Conditions (3,018 cfs)	Run 3a Preferred Alternative (2,366 cfs)	Percent change from Run 1 to Run 3a
Transition: (Canyon Mouth to Shields)	49.2	41.9	30.0	28.5
Urban: (Shields to Boxelder confluence)	86.4	70.5	56.5	19.8
Warm: (Boxelder to County Road 32E)	169.1	134.5	91.7	31.8

The first three columns in this table present the average width (in meters including both sides of the river) of the 5-year floodplain for three RHAF river segments under various 5 year flow scenarios. The percent change from Current Conditions to the Preferred Alternative can be calculated as a way to present the expected change in ecologic services. This methodology and these river segments, are explained the RHAF (City of Fort Collins, 2015a). Due to bank armoring and channel constrictions the riparian forest is narrow for significant lengths in each of these river segments. In contrast, the sections with more natural low-lying floodplain topography are more likely to receive the benefits of inundation. For example, as portrayed in the photo below, the river section downstream of Lemay Ave. currently inundates the forest under the 5 year flow. WithNISP the 5 year flow will not extend into the forest at all.



The analysis should be revised to provide a spatial assessment of inundation alterations and the effects to the riparian environment, as described above.

10.8 COMMENTS REGARDING WILDLIFE ANALYSES

10.8.1 Inadequate Analyses of Impacts to Wildlife

Comment: The SDEIS analysis for wildlife primarily addresses the direct impacts at or near the site of the reservoirs. Indirect impacts for wildlife along the Poudre River rely on the Riparian and Wetland analysis, which have weaknesses as discussed in this Section 10, and therefore are not a reasonable perspective from which to analyze impacts to wildlife. The general conclusion that the project would likely affect the overall abundance of wildlife but would not alter species composition and distribution; and that species would likely adapt to the new habitat conditions is not supported by any additional information and is inconsistent with fundamentals of wildlife biology. The wildlife analyses and conclusions should be revised, in conjunction with revisions to the wetlands and riparian area analyses, to address the deficiencies described above.

10.8.2 No Basis for Assertion of Adaption of Species

SDEIS Section 4.10.3.2, District's Preferred Alternative, Poudre and South Platte Rivers, Page 4-272

Statement: "*The predicted changes in vegetation would occur slowly over a long period of time and would likely be negligible and imperceptible given the dynamics of riparian areas. Wildlife using these habitats typically use a wide range of aquatic, wetlands, and riparian habitats and would likely adapt to the new habitat conditions that currently occur within the riparian areas of the rivers.*"

Common: The changes to the flow regime under the preferred alternative will begin abruptly once the Project is constructed and the ripple effect through the system will not be "slow" given plants, especially herbaceous plants, respond to real time conditions. There will be a slower response to woody vegetation, however drought stress could cause decadence to some stands within years rather than decades.

To say wildlife will adapt to the changes fundamentally mischaracterizes the expected outcome. As vegetation changes it is likely to cause a concurrent change in wildlife species composition and diversity. Species that "adapt to the situation" will likely be those species common to urban settings and not the suite of riparian dependent species.

The wildlife analyses and conclusions should be revised, in conjunction with revisions to the wetlands and riparian area analyses, to address the deficiencies described above.

10.9 COMMENTS REGARDING CUMULATIVE EFFECTS, AVOIDANCE, MINIMIZATION, AND MITIGATION

10.9.1 Complete Analysis Is Needed

SDEIS Appendix F
Conceptual Mitigation Plan

Comment: The adequacy of the cumulative effects and mitigation planning cannot be evaluated without better analysis of the critical factors discussed in this Section 10. The impacts to the riparian and wetland resources need to be quantified in order to address them. The SDEIS rationale that the impacts will be imperceptible, negligible, or minor and that Alternative 2 will accelerate and/or reinforce the well-established trajectory is not substantiated.

10.9.2 Current Proposal Omits Certain Needed Elements

SDEIS Appendix F
Statement: "*Proposed Conceptual Mitigation Plan …*"

Comment: The proposed avoidance, minimization, and mitigation described in the SDEIS lack certain required elements, such as peaks flows and other measures to specifically address the issues identified in this Section 10. The key missing elements of the current proposed approach are:

- Provision of peak flows to compensate for narrowing of all riparian flow related functions and wetland loss.
- Provision of long term management plans for improving river floodplain access as well as periodic manual scour (creation of bare sites) to support maintenance of future forests and resilience of native woody species.
- Provision of means to address the loss of critical ecological services associated with flooding in the riparian zone.

Peak flows are the cornerstone of riparian and wetland resources. Peaks flows therefore should be a central component to any plan to avoid, minimize, or mitigate the impacts. Any avoidance, minimization, and mitigation should also address the issues described above.

APPENDIX A:
CITY OF FORT COLLINS' COMMENTS ON SUPPLEMENTAL DRAFT ENVIRONMENTAL IMPACT STATEMENT FOR THE NORTHERN INTEGRATED SUPPLY PROJECT

LIST OF SELECTED PREPARERS OF COMMENTS

1. CITY OF FORT COLLINS STAFF

Donnie Dustin, P.E. Donnie Dustin is the Water Resources Manager for the City of Fort Collins Utilities. His education includes a B.S. in Geology from James Madison University in Virginia and a M.S. in Civil Engineering (with emphasis in Water Resources Planning and Management) from Colorado State University ("CSU"). He is a registered professional engineer in Colorado and has been employed by the City of Fort Collins for approximately 17 years, 10 of which has been with the Utilities Water Resources Division. His duties and expertise include developing policies related to water supply system operations and development, and demand management. He has provided criteria and guidance related to hydrologic and water rights allocation modeling. He oversees the management of the City's raw water supplies including the administration of relevant water rights decrees. He also serves on the governing boards of two irrigation companies.

Keith Elmund, Ph.D. After serving as an officer in the U.S. Air Force, Keith came back to CSU and finished his Ph.D. in environmental microbiology. He has been with the City of Fort Collins Utilities for over thirty-five years and since 1984 has served as Environmental Services Manager. In this role, he manages both the City's certified drinking water quality and pollution control labs. Beginning in 2006, he helped implement the Poudre River Monitoring Alliance that was part of EPA's award winning "performance track" environmental leadership program. This ongoing program joins together the Cities of Fort Collins and Greeley, the Town of Windsor, the Boxelder and South Fort Collins Sanitation Districts, and Carestream Health, with CSU, the North Front Range Water Quality Planning Association and the Colorado Water Quality Control Division in a collaborative effort to monitor and help protect water quality in over 42 miles of the lower Poudre.

Cameron Gloss, AICP. Cameron Gloss is the Planning Manager for the City of Fort Collins. Since entering the field in 1984, his public and private sector experience includes an array of work including comprehensive community planning, subarea and neighborhood planning, transportation master planning, land development review, sustainability modeling, and the crafting of land use regulations. Prior to his most recent role with the City of Fort Collins, Cameron spent five years working with the Fort Collins offices of both AECOM and Clarion Associates where he acted as a Senior Planner, leading community planning projects over a dozen states, primarily within the western region. Mr. Gloss holds a B.S. in Geography (urban emphasis), Arizona State University, 1983. He is a member of the American Institute of Certified Planners.

Adam Jokerst, P.E. Adam Jokerst is a Water Resources Engineer for the City of Fort Collins Utilities. His education includes a B.S. in Biological and Agricultural Engineering from

the University of Arkansas and a M.S. in Civil Engineering from CSU. He is a registered professional engineer in Colorado and has been employed by the City of Fort Collins for approximately three years with the Utilities Water Resources Division. His main function at the Utilities is to provide hydrologic, water rights, and system modeling used to assess the Utilities' current and future water and infrastructure needs. In addition, he acts as project manager for the Halligan Water Supply Project. He is also knowledgeable in the areas of water resources engineering, planning and management and provides his expertise to develop policies, maintain and protect water rights, and provide water supply and use information.

Bonnie Pierce, Ph.D. Bonnie Pierce is an Environmental Data Analyst in the Fort Collins Environmental Services Department. Dr. Pierce's work for Fort Collins focuses on climate change and air, water, and hazardous waste matters including those related to oil and gas operations. Dr. Pierce is the City's project manager for the Poudre River Area and North College Ave. Innovation District Brownfields Assessment project. Her previous job assignments include Program Principal and Senior Project Manager for the Solid and Hazardous Waste Division for the Wyoming Department of Environmental Quality and Associate Director for Natural Resources, State of the Parks program, National Parks Conservation Association. Dr. Pierce received her Ph.D. in Soil Science from CSU.

Jill Oropeza. Watershed Specialist for the City of Fort Collins Utilities and Secretary/Reserved Seat Member of the Coalition for the Poudre Watershed. Jill has worked as the Watershed Specialist for the Fort Collins Utilities Source Watershed Program since 2007. The City's Watershed Program monitors water quality of the Upper Poudre River and Horsetooth Reservoir in collaboration with the City of Greeley and the Tri-Districts in effort to identify and address issues that affect drinking water treatment operations and watershed health. Jill holds an M.S. decree from CSU in Ecology and has over 12 years of experience working on natural resource issues in the state of Colorado.

Eric R. Potyondy, Esq. Eric Potyondy is an Assistant City Attorney in the Fort Collins City Attorney's Office. Mr. Potyondy's work for Fort Collins focuses on water-related issues, including water rights, water quality, and related matters. Prior to working for Fort Collins, Mr. Potyondy was in private practice in Colorado for nearly six years, with his practice focusing almost exclusively on water rights and related matters. Mr. Potyondy has litigated numerous cases in the Colorado District Courts for various Water Divisions and the Colorado Supreme Court. Prior to private practice, Mr. Potyondy worked for two years as the water law clerk for Hon. Chief Judge Roger A. Klein, District Court, Water Division 1, State of Colorado. Mr. Potyondy received his J.D. degree and his B.A. degree from the University of Colorado.

Kenneth C. Sampley, P.E. Ken Sampley manages the Water Utilities Engineering Division of Fort Collins Utilities consisting of a multi-disciplinary team of 13 employees that provide stormwater and floodplain management, flood warning and emergency preparedness, stormwater master planning, stream rehabilitation and stormwater water quality, development review for new stormwater, water and wastewater improvements, and water distribution and wastewater collection system capacity. Ken is a licensed professional engineer in the State of

Colorado and has over 34 years of experience. He worked for 3 years in consulting engineering, 26 years for the City of Colorado Springs, and the last 5 years for the City of Fort Collins. Ken graduated from CSU with a B.S. degree in Civil Engineering, specializing in hydrology and hydraulics. He obtained his M.P.A. degree from the University of Colorado.

Jennifer Shanahan. Jennifer Shanahan is an environmental planner for the City of Fort Collins, Natural Areas Department. Jen leads and participates a variety of planning processes related to management of the City's 42 natural areas with a particular focus on a spectrum of issues and projects surrounding the Poudre River. These include collaborative landscape-level planning, application of river science to policy and management, report development on integrative river models and monitoring projects, and communication of technical Poudre River issues to the broader community. She holds an M.S. degree from the Department of Forest Rangeland and Watershed Stewardship at CSU, with a research focus in riparian restoration.

John Stokes. John Stokes is the Director of the City's Natural Areas Department. The Department manages over 40,000 acres of conserved land, including approximately 1,800 acres along the Poudre River in Fort Collins. John is a member of the Colorado Water Institute initiative the Poudre Runs Through It, a regional collaborative group working on issues related to river health and water supply. In that capacity John has initiated an instream flow collaboration with various regional partners as well as an annual Poudre River Forum that has generated substantial participation from the community. John is a member of the South Platte Basin Roundtable as one of two environmental representatives. In 2014 John was recognized by the Colorado Water Trust with the David Getches Flowing Waters Award which recognized John's efforts to restore and improve Poudre flows.

2. OUTSIDE CONSULTANTS

Daniel Baker. Daniel Baker is a research scientist at CSU. In the summer of 2012 Dan completed a postdoctoral fellowship at Johns Hopkins University, working with the National Science Foundation-funded National Center for Earth Surface Dynamics and the Intermountain Center for River Rehabilitation and Restoration based at Utah State University. He completed his PhD in civil and environmental engineering in 2009 at CSU, with a focus on river engineering and stream restoration. Dan's research focuses on the interaction between physical and biochemical processes in streams, the effects of flow extraction on stream geomorphology and sediment dynamics, and the application of Geographic Information Systems (GIS) technology to evaluate reach-scale conditions from digital elevation models. Other current projects focus on developing urban stream restoration guidance with the USACE and monitoring post-fire sediments and aquatic insects on the Poudre River.

Brian Bledsoe. Brian Bledsoe is a professor of Civil and Environmental Engineering at CSU. Brian has more than 25 years of experience as an engineer and environmental scientist in the private and public sectors, including more than 20 years of experience in stream and wetland restoration. Brian's research and teaching are focused on watershed and river processes at the interface of hydrology and aquatic ecology. He has worked in the private sector as a consulting

engineer and surveyor, and for the state of North Carolina as a stream and wetland restoration specialist and nonpoint source program coordinator. Brian has served as a peer reviewer on recovery programs for the Platte and San Juan Rivers, the U.S. Environmental Protection Agency's Environmental Monitoring and Assessment Program (EMAP), as well as on numerous large-scale restoration projects including the Everglades and Louisiana coastal areas. Brian is a licensed professional engineer in Colorado and North Carolina.

Claudia A. Browne. Claudia Browne, is a Water Resources Specialist and the Southern Rocky Mountain Bioregion Leader at Biohabitats Inc. (since 2004), a national ecological consulting firm specializing in restoration, conservation planning and regenerative design. Ms. Browne has over 30 years of experience in environmental protection and water resource management with expertise in habitat assessments, riparian and wetland restoration and maintenance, groundwater monitoring well installations, surface water and groundwater data collection and evaluation, wetland permitting soil sampling and data evaluation, point-flow analysis, water budgets, conceptual hydrogeologic model development, and groundwater modeling. Ms. Browne has been the Project Manager for the Fort Collins Wetland and Riparian Restoration On-Call contract since 2008. As such, she has participated in a wide range of City's river projects including assisting with the Poudre River Management Plan update; assessing the groundwater-surface water regime for multiple properties, and; restoration planning efforts including prioritizing potential restoration projects, identifying focal species and habitat types, and helping develop restoration concept plans. Ms Browne is also providing ecological master planning assistance for the Poudre River Downtown Master Plan for the City. Her role has included developing habitat goals and objectives for 10 miles of river through the City's urban core, mapping priority habitat areas, collaborating with wildlife biologists and stakeholders, and identifying opportunities and constraints. Ms. Browne received her B.S in Natural Resources from Cornell University and her M.S. in Ecology from CSU.

Jordan Furnans, Ph.D., P.E., P.G. Dr. Furnans is a Senior Water Resources Engineer with INTERA Incorporated, and engineering and geosciences consulting firm in Austin, TX. Dr. Furnans holds a PhD in civil engineering and an M.S.E. degree in environmental and water resources engineering, both from the University of Texas at Austin, and a B.S.E. degree in civil and geological engineering from Princeton University. Dr. Furnans has 16 years of professional experience that encompasses both field hydrologic data collection and the analysis of data through the development and application of numerical models. He specializes in the areas of water right accounting; coupled field and model hydrodynamic investigations of estuaries, lakes, and rivers; linking water quality and hydrodynamics in natural systems; water availability modeling; watershed hydrology planning and management; hydrographic and sedimentation survey methods; and freshwater inflow and instream flow requirements for ecosystem health. Some of Dr. Furnans' recent experience includes developing expert testimony for water rights litigation efforts, accounting plan development and water rights analysis, performing model reviews, developing an automated bathymetric data processing system for volumetric and sediment surveying, aiding development of instream flow recommendations for rivers in Oklahoma, and modeling circulation in lakes.

Andrew Herb. Mr. Herb, owner of AlpineEco (founded in 2007) has worked as an ecologist in the Rocky Mountain Region for over 16 years. Although most of his work has been in Colorado and Utah, he has worked in nearly all the Rocky Mountain, Great Plains, and Great Basin States, as well as in Korea, Japan, Guam, and Puerto Rico. His work involves most aspects of field ecology, with a focus on wetlands. He is currently the president of the Rocky Mountain Chapter of the Society of Wetland Scientists, which is an international organization committed to improving the management of wetlands through sound science and education. He is also the founder and chairperson of SWS's Wetland Restoration Section, which brings together professionals from around the world to share information on wetland restoration. His commitment to science and the environment, combined with his practical approach to problem-solving results in creative, cost-effective, and ecosystem-friendly approaches to projects. Mr. Herb is also the owner of AlpineEco Nursery (founded in 2012) which provides native wetland and riparian plants for ecological restoration.

William Lewis, Jr., Ph.D. Dr. Lewis is professor and Director of the Center for Limnology, University of Colorado Boulder, and serves as Associate Director of the University of Colorado at Boulder Cooperative Institute for Research in Environmental Sciences. His interests in research and teaching include ecological characteristics and processes of inland waters (lakes, streams, and wetlands). Research for Dr. Lewis and his students focuses mainly on biogeochemical processes, ecosystem modeling, effects of water pollution and hydrologic changes on aquatic ecosystems and organisms, composition and abundance of aquatic organisms under natural and anthropogenically altered conditions, and productivity of aquatic ecosystems. Dr. Lewis has published over 200 journal articles related to these research interests. He is recipient of the Renewable Natural Resources Foundation Sustained Achievement Award and of the Baldi Award and the Naumann-Thienemann Medal of the International Society for Limnology. He has served as a member of the Board on Environmental Studies and Toxicology and on the Water Science and Technology Board of the National Academy of Sciences National Research Council.

John Putnam, Esq. John Putnam is an attorney and partner at the law firm of Kaplan Kirsch & Rockwell, LLP, in Denver. Mr. Putnam's practice emphasizes counseling and litigation for public and private entities on complex issues of environmental law, especially for large public and public/private projects. Mr. Putnam has extensive experience providing clients nationwide with strategic advice on large and controversial development and transportation projects, including airports, highways, real estate development, telecommunications facilities, and other infrastructure. He counsels clients regarding a wide range of environmental, transportation and development issues, including the National Environmental Policy Act, wetlands, air quality, climate change, sustainability, air toxics, noise, tolling and innovative finance, land use, endangered species, floodplains, municipal law, transportation regulations and Native American jurisdiction. Mr. Putnam received his J.D. degree from the University of Chicago and his B.A. degree from Williams College.

Jennifer Roberson. Jennifer is a professional research assistant with the Center for Limnology at the University of Colorado Boulder, within the Cooperative Institute for Research

in Environmental Sciences. Her duties include data assembly, data analysis, and synthesis of information for reports and publications of the Center for Limnology. She holds a Bachelor's Degree in Ecology and Evolutionary Biology from the University of Colorado Boulder and has extensive experience in fieldwork, laboratory analyses, data analysis, and document preparation related to water quality, aquatic life, water quality regulations and related matters specifically for Colorado.

Abstract. More than a century of dam construction and water development in the western United States has led to extensive ecological alteration of rivers. Growing interest in improving river function is compelling practitioners to consider ecological restoration when managing dams and water extraction. We developed an Ecological Response Model (ERM) for the Cache la Poudre River, northern Colorado, USA, to illuminate effects of current and possible future water management and climate change. We used empirical data and modeled interactions among multiple ecosystem components to capture system-wide insights not possible with the unintegrated models commonly used in environmental assessments. The ERM results showed additional flow regime modification would further alter the structure and function of Poudre River aquatic and riparian ecosystems due to multiple and interacting stressors. Model predictions illustrated that specific peak flow magnitudes in spring and early summer are critical for substrate mobilization, dynamic channel morphology, and overbank flows, with strong subsequent effects on instream and riparian biota that varied seasonally and spatially, allowing exploration of nuanced management scenarios. Instream biological indicators benefitted from higher and more stable base flows and high peak flows, but stable base flows with low peak flows were only half as effective to increase indicators. Improving base flows while reducing peak flows, as currently proposed for the Cache la Poudre River, would further reduce ecosystem function. Modeling showed that even presently depleted annual flow volumes can achieve substantially different ecological outcomes in designed flow scenarios, while still supporting social demands. Model predictions demonstrated that implementing designed flows in a natural pattern, with attention to base and peak flows, may be needed to preserve or improve ecosystem function of the Poudre River. Improved regulatory policies would include preservation of ecosystem-level, flow-related processes and adaptive management when water development projects are considered.

Key words: algae; aquatic insects; channel geomorphology; climate change; designed flow regime; fish; hydrology; modeling; NEPA policy change; probabilistic Bayesian Network model; riparian community; water development.

Introduction

Rivers have been heavily modified on a global scale due to hydrologic alteration by dams and water extraction, leading to extensive ecological change (Nilsson et al. 2005, Dudgeon et al. 2006, Vörösmarty et al. 2010). Ongoing demand for municipal and agricultural water will continue to stress river ecosystems, but those uses are countered by growing interest in restoring rivers to sustainable ecosystem conditions, while still accommodating human needs. Providing water for traditional uses while sustaining ecosystem function poses challenges, particularly in semiarid and arid landscapes where water demand is high (Grafton et al. 2013). Thus, restoration practitioners seek to optimize the functional

impact of limited water to maximize ecological outcomes (Yarnell et al. 2015).

River restoration requires understanding linkages between specific flow conditions and ecosystem attributes to provide clear, quantified management targets (Poff and Schmidt 2016, Webb et al. 2017). In heavily altered systems, restoration to a "natural," pre-development state is generally not an option, particularly when future climate is uncertain (Moyle 2014, Poff 2018). Alternatively, specifying flows to restore functions that are ecologically important and socially desirable may be possible. So-called "designer flows" (sensu Acreman et al. 2014) can, in principle, help meet both ecosystem and human needs for water (e.g., Kiernan et al. 2012, Chen and Olden 2017). For heavily appropriated systems with multiple competing users, it is critical to understand how alternative management interventions will affect existing economic and social benefits provided by the river (Northern Colorado Water Conservancy District 2017). It is also important to understand the biophysical processes needed to promote long-term ecosystem functioning, including dynamic channel features and desirable aquatic and riparian species, which may have different requirements. Appropriate ecosystem modeling that incorporates a variety of future flow conditions is useful for such an evaluation.

The Cache la Poudre River (hereafter, Poudre River) is a southern Rocky Mountains, USA, mountain and plains system in northern Colorado that has been altered by heavy agricultural and urban water use since European settlement in the 1870s. Despite streamflow changes, intensive agricultural and urban land use, and nonnative species establishment, the Poudre River remains a valued amenity both socially and functionally, particularly where it flows through the City of Fort Collins (City). Declining ecological condition of the Poudre River has been documented (City of Fort Collins 2017) but a strong interest has developed among the public and government institutions to restore and promote a dynamic and functioning river that provides amenities. However, extensive dam and diversion infrastructure, proposed additional water development near Fort Collins (U.S. Army Corps of Engineers 2018), and climate change, complicates appropriate management strategies.

Management of arid-land systems such as the Poudre River requires understanding flow-ecology relationships (Poff et al. 2010), as well as anticipating future hydrologic change, to illuminate restoration strategies responsive to likely evolution of the river ecosystem. To accomplish this, we first developed a comprehensive, multi-compartment model informed by empirical data showing how hydrology and other variables (e.g., channel structure, water temperatures, and nutrients) drive important riverine geomorphic processes and associated ecosystem endpoints in the coupled aquatic-riparian system. Thus, our model differs from other strictly flow-driven modeling approaches such as ELOHA (Poff et al. 2010), which is effectively a rapid assessment tool useful for multisite comparisons of potential river degradation. Following model development for the current ecosystem, we evaluated how "scenarios" of future hydrologic conditions, ranging from status quo to expanded water development and climate change, may alter the Poudre River ecosystem. We also designed and modeled hypothetical flow regimes that we thought might achieve acceptable ecosystem outcomes under active flow management. Our aim was to produce a scientifically credible and comprehensive analysis to inform the public and assist water managers interested in sustainable management of the Poudre River ecosystem. Here, we detail model development and implementation to identify aspects of an ecologically effective flow regime that might be attainable through active management of water infrastructure, including proposed development in the Poudre River basin. This modeling effort may also inform predictions and management perspectives for other heavily altered river ecosystems in the western United States and elsewhere.

Methods

Study site

The Poudre River drainage (~2,865 km^2) originates in high-elevation mountains (>4,000 m above sea level) west of Fort Collins, Colorado, USA (U.S. Geological Survey [USGS] gage 06752260, Fig. 1). Above 1,900 m elevation, the river is a moderate to high gradient, high-velocity, cobble-bottomed stream that supports a trout-dominated fish community and diverse aquatic insects in orders Ephemeroptera, Plecoptera, and Trichoptera (EPT taxa). In the study area just downstream, the channel meanders through a lower gradient, less confined transition zone between mountains and prairie (~1,600–1,900 m elevation) and supports cool water tolerant trout, native catostomids and cyprinids, and fewer EPT taxa while adding Diptera (Fausch and Bestgen 1997). Native narrowleaf and plains cottonwood (*Populus angustifolia* James and *P. deltoides* W. Bartram ex Marshall, respectively) and their hybrids, willow (*Salix* spp.) and green ash (*Fraxinus pennsylvanica* Marshall), as well as nonnative species crack willow (*Salix fragilis* L.), Siberian elm (*Ulmus pumila* L.), and Russian olive (*Elaeagnus angustifolia* L.), dominate the riparian zone. Gravel, cobble, sand, and silt predominate in this montane-prairie ecotone. Downstream, the warm-water Poudre River continues another 60 km to the South Platte River, Missouri–Mississippi River watershed.

The 21 km long transition zone reach of the Poudre River, as just described, historically had multiple and sinuous channels and a broad floodplain with oxbows (Fig. 2a). As urbanization and development proceeded, riverbanks were structurally hardened to prevent channel meandering and property destruction during flooding, which resulted in a straighter and mostly confined

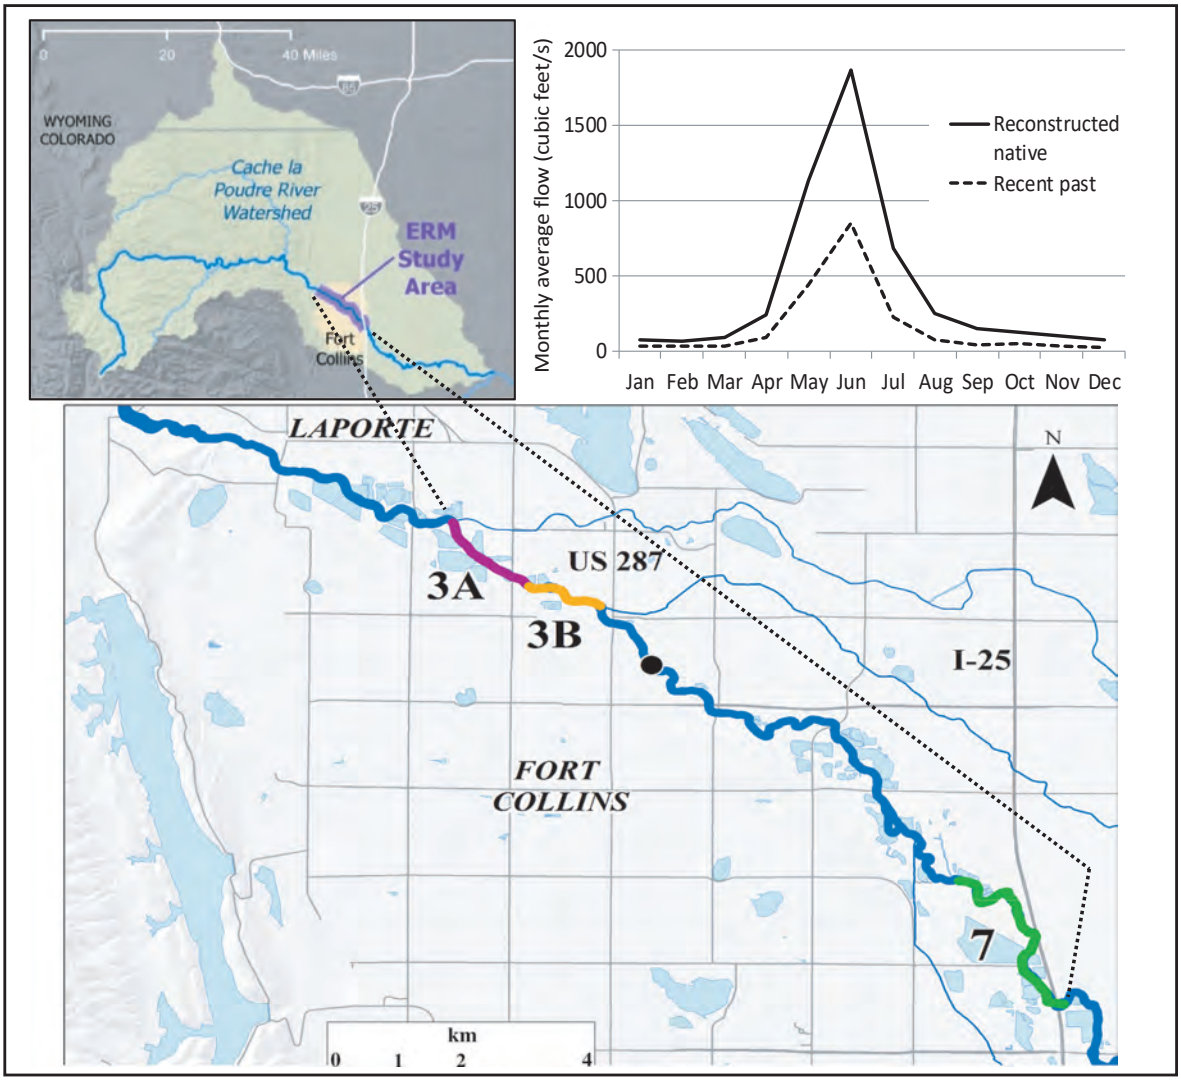

FIG. 1. The Ecosystem Response Model study area in the Cache la Poudre River watershed near Fort Collins, Colorado, USA. The Poudre River Basin map (upper left; 1 mile = 1.61 km) shows the study area segment, which is expanded below to show confined, moderately confined, and least confined reaches (3a, 3b, and 7, respectively) from up to downstream. Reduced mean monthly flow of the Poudre River in Fort Collins (water years 1975–2005) for the altered recent past hydrologic scenario (from flow gage measurements, USGS # 06752260; 1 cubic foot/s = 0.03 m^3/s) is compared to the reconstructed native (pre-development, modeled flows) flow regime (upper right; Shanahan et al. 2014).

single-thread system (Fig. 2b). Native cottonwood and willow dominate the riparian community, although non-native trees are increasing. Three of eight urban to sub-urban river corridor sub-reaches (Fig. 1b) were chosen for modeling because they represented the range of upstream to downstream channel constriction and floodplain connectivity through the 21 km long study area. Reach 3a (confined reach) is highly confined upstream by bank stabilization and has only a few opportunities for floodplain restoration. Just downstream, Reach 3b (moderately confined reach) is partially confined, offering modest restoration opportunity for natural riverine and riparian functions, while downstream Reach 7 (least confined reach) has a mix of armored banks and open floodplain and, potentially, the greatest channel-floodplain restoration opportunities.

Conceptual hydrologic calendar

To illustrate how changes in flows qualitatively affect important geomorphic and biological attributes, we developed a conceptual Poudre River hydrologic calendar (Fig. 3). We developed this model from stream ecology literature (e.g., Allan 1995), regional and Poudre-River-specific ecological and geomorphic traits (Fausch and Bestgen 1997, Merritt and Poff 2010, Wohl et al.

a) 1937

b) Recent, circa 2005

FIG. 2. Cache la Poudre River along a section of the ERM study reach, Fort Collins, Colorado, (a) in 1937 and (b) recently (circa 2005). Panel a shows a meandering channel, with a wide, unimpaired zone of channel movement across the floodplain and presence of cottonwood forests of various ages. Panel b depicts the confined channel after nearly a century of land use changes that simplified and straightened the river, reduced channel migration and the associated rejuvenation of riparian habitat, narrowed the riparian zone, and confined the channel with hardened banks and associated pit ponds following gravel extraction.

2016), as well as from observations and expert judgement based on the authors' extensive field sampling over the last two or more decades. We adopted this river view after discussions that gravitated from a narrowly focused subset of flow-biology relationships to a holistic Poudre River ecosystem model useful to predict responses of geomorphic and biological indicators to flow and changes in management. This model reflects our aim of counterbalancing the unintegrated and few species-specific approaches commonly used in environmental assessments and resource management decision-making.

Strongly seasonal spring and early summer peak flows foundational to a functioning snowmelt river ecosystem set the physical habitat template for the Poudre River. Increased discharge from high-elevation snowmelt recruits streamside wood into the channel, mobilizes fine sediments, and scours algae, gravels, and cobbles to create aerated spawning substrates for fishes, including spring-spawning salmonids. Cool water fishes reproduce and young of spring-spawning salmonids emerge. High magnitude flow peaks maintain channel width and complexity and sometimes connect the river and floodplain, forming seasonal wetlands of variable extent and duration depending on snowmelt volume. Descending limb flows and associated sediment deposits create germination sites and enhance seedling survival for colonizing plant species (e.g., *Populus* and *Salix*) and enable early life stage fish dispersal to complex, secondary-channel backwaters. In summer, relatively stable base flows facilitate rapid growth of tree seedlings as well as reproduction and growth of native fishes, trout, and aquatic insects that require cleansed and oxygenated gravel beds. Stable autumn and winter base flows of appropriate magnitude support spawning fish and enhance survival of trout eggs and insects in shallow riffles.

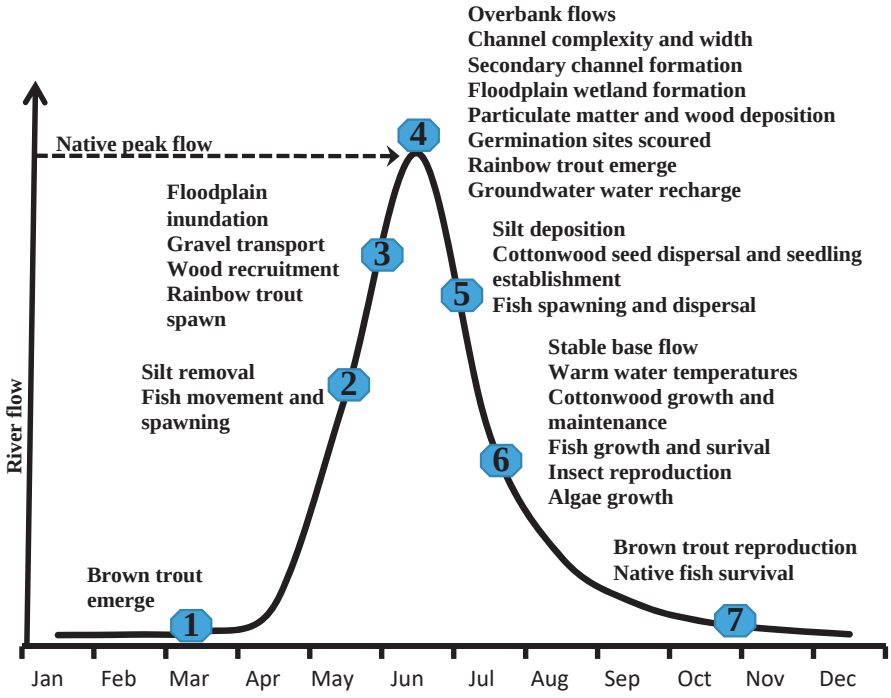

FIG. 3. Poudre River hydrology calendar, which conceptually describes flows and timing of functions those flows support to produce physical, chemical, and biological responses.

In contrast to the historical conditions portrayed by the hydrologic calendar, the contemporary Poudre River is highly altered (Appendix S1: Tables S1, S2). Extensive water storage infrastructure was developed to supply agriculture and municipal use, aggregate mining and urban development resulted in confined channels, and the many diversion dams upstream of the city (Fig. 1, Appendix S1: Table S1) divert a large proportion of river flow for much of the year. Storage and diversions reduce pre-development (native) peak and base flows (flows that would occur in the absence of diversions and other management) by 59% and 57%, respectively (Bartholow 2010, Shanahan et al. 2014). These hydrologic changes reduce sediment flushing and contribute to channel simplification thus reducing river amenities including a quality fishery or native riparian corridor (Wohl et al. 2015).

Model development and structure

Hydrologic alteration induces multiple, linked ecosystem responses, including changes to sediment transport, channel maintenance, and floodplain and wetland inundation, which affect distribution and abundance of in-channel and riparian biota (Nilsson and Svedmark 2002). Thus, we developed a multi-compartment Ecosystem Response Model (ERM) to evaluate future trajectories and complex and interacting biophysical functions under various Poudre River flow regimes, using a probabilistic Bayesian Network model. Here, we describe generalities of ERM development; additional details regarding probability tables and relationships used to calculate responses to flows and other variables are in Shanahan et al. (2014), Supporting Information (SI; Data S1) and City of Fort Collins (2019).

The probabilistic ERM network conceptualizes cause-and-effect relationships between flow regime, sediment, temperature, and ecological states (Fig. 4). Most relationships are based on conditional probabilities such that effects of one driver on a response will vary depending on other driver variables. Use of conditional probabilities leads to complex model parameterization but allows for incorporation of many information types to produce predictions about physical, chemical, and biological resources, and interactions among them. Because hydrology is a known master driver of physical and ecological conditions in streams (Poff et al. 1997, 2010), the ERM can be used to predict outcomes under various conditions including native flows, present altered flows, and future regimes resulting from additional water storage or climate change. The ERM incorporated major ecosystem components and interactions and retained advantages of a Bayesian Network approach (Uusitalo 2007) including (1) integration of various ecosystem functions typically evaluated as independent variables, (2) incorporation of various data types ranging from quantitative empirical analyses to qualitative expert judgment, (3) explicit quantification and incorporation of uncertainty, and (4) flexibility to test an array of scenarios.

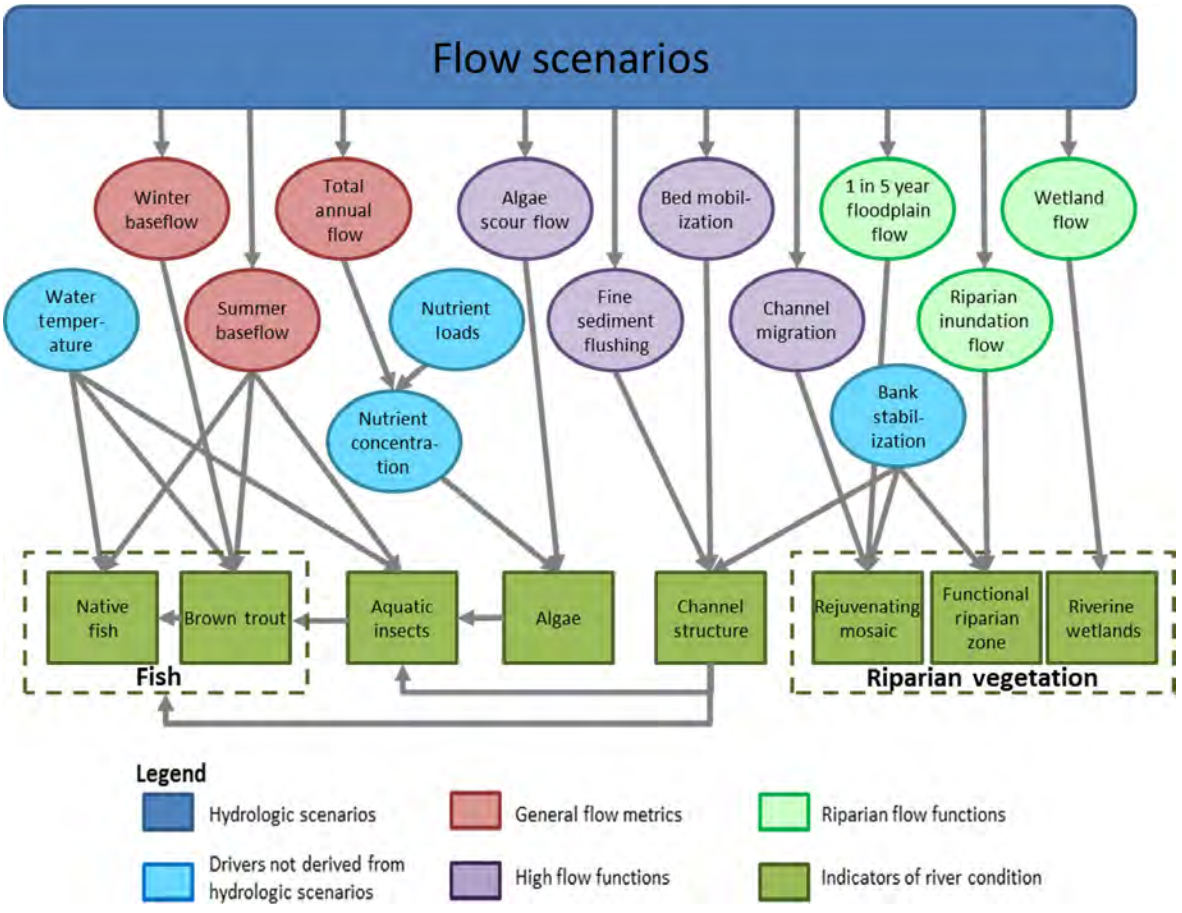

FIG. 4. Structure of the Bayesian network for the Poudre River Ecological Response Model (ERM), which links flow regime drivers, including aspects of magnitude, duration, frequency, and variability, to various flow metrics and functions, and their influence on indicators of river condition, the sum of which form ecosystem responses. Arrows between flow metrics and function nodes to indicators of river condition are predictive relationships in the model. Arrows linking indicators of river condition reflect interactions.

Indicators were formulated using combinations of quantitative channel hydraulics, empirical flow-ecology relationships based on continuous or categorical responses, and interacting effects of flow mediated through various combinations of base and peak flow, temperature, nutrients, and bed stability. Indicators included in the ERM (see Appendix S1: Table S3) were: (1) channel structure (substrate and channel geometry template for physical and ecological processes), (2) algae (basal food web resource, but unaesthetic and detrimental when excessive), (3) aquatic insects (species composition and abundance indicates flow regulation, water quality, and is a critical food web link), (4) native fish (indicates channel condition and flow regulation effects), (5) trout (mainly nonnative brown trout (*Salmo trutta* L.), which have high angler value and are a sensitive indicator of thermal and hydrologic regimes), (6) rejuvenating mosaic forest (width of multistage riparian forest with species adapted to disturbance), (7) functional riparian zone (river-connected area that supports biogeochemical processing, flood peak attenuation, sediment deposition, episodic aquatic habitat, and a productive vegetative community), and (8) riparian wetland (floodplain area inundated with sufficient frequency and duration to support wetland plants). Indicators were grouped into three types, based mainly on the amount of quantitative data available to describe them. The first group, for which quantitative data were available, included channel structure and three indicators of riparian condition, for each of the three separate river reaches. Because quality and quantity of stream habitat are determined by the interaction between flow and the structure of the river channel, the effects of flow changes on the ecosystem must be considered in the context of the current channel structure and its variability along the river (Brewer et al. 2016, McManamay et al. 2016). To quantify the effects of channel structure and associated moderate to high flows on indicators in the ERM (i.e., algae, native fish, trout, aquatic insects, and three riparian vegetation indicators), shear stress and effective

discharge analyses were performed at representative locations in each of the three reaches modeled along the Fort Collins river corridor. Hydraulic modeling identified discharges at which critical thresholds of shear stress, associated with riverbed flushing and bed and channel mobilization, were met, based on flow characteristics, channel geometry, and substrate composition in each reach (details in Shanahan et al. 2014; the full channel structure model data and a detailed narrative is in SI, and Data S1; the full Excel spreadsheet is also available from the senior author upon request). An annual high flow pulse capable of flushing surface deposits of fine sediment was assumed needed to ensure ecological functioning, while widespread mobilization of the coarse river bed sediments had a longer, two-year average return interval based on the current management infrastructure, and on interannual flow variability including multi-year dry periods. Descriptions and data sources for cross-sectional geometry were used to perform shear stress and effective discharge analyses, discharge–shear-stress rating curves, the HEC-RAS model (U.S. Army Corps of Engineers 2009), hydraulic model median grain size (d_{50}), and flow records for each of the three reaches, as described in Shanahan et al. (2014), SI (Data S1) and City of Fort Collins (2019).

Geospatial probability modeling was used to determine floodplain area available for the three riparian indicator responses. Reach-specific empirical models related flood flow inundation to riparian forest species and functional group composition. These relationships used detailed riparian plant distributions (Shanahan 2009) and measured presence of the rejuvenating mosaic, functional riparian zone, and riverine wetlands, and were modeled as a function of exceedance probability from a 30-yr flow record (USGS streamflow gages) using logistic regression. Compared to the other two riparian indicators that mainly require floodplain inundation, the rejuvenating mosaic requires higher shear stresses to induce channel migration and to disturb and scour floodplain germination sites for seeds. Exceedance probability was mapped using local rating curves developed with HEC-RAS 1-D hydraulic models (U.S. Army Corps of Engineers 2009), a 1-m^2 digital elevation model, and river flow duration curves. Reconstructed historical flows and future climate change and water development scenarios were used to recalculate and reproject future exceedance probabilities and corresponding distributions and area of vegetation, which informed probabilistic model parameters.

The trout indicator was the sole member of the second indicator group, which was based on an empirical flow-ecology relationship augmented with expert judgement. The trout indicator was based in part on field sampling that related abundance of young brown trout captured in autumn samples (n = 16 yr) as a function of the river flow level in the previous winter when eggs were incubating and hatching. This relationship indicated that higher winter flows of about 1 m^3/s, for example, had a relatively high 0.67 probability of producing a larger number (>20) of young trout per year, while low flows < 0.28 m^3/s had an 80% probability of producing 5 or fewer trout; intermediate flows produced an intermediate number of young trout. The empirical relationships between winter flow categories and young trout abundance were used to describe the probabilities of having a trout fishery in one of four categories, or states (−−,−, 0, +) that reflect the number of age classes present, their abundance, and reproductive success (present state is between − and 0). Several other factors also influenced this indicator (see Fig. 4), and these were assigned independent probabilities (by expert judgement) to place trout into one of the four states in a process similar to that described below for qualitative indicators (see SI; Data S1; City of Fort Collins 2019). We also weighted driving variables for each indicator in the ERM according to their relative importance. Using trout as an example, weights for winter baseflow, summer baseflow and temperature, and channel structure were relatively high and equal (0.27 each, total of 0.81), reflecting that habitat and temperatures are relatively more important, while invertebrates received a lower relative weight (0.19), reflecting that trout can likely obtain ample food even in a relatively degraded system. We also detail the full progression of the trout indicator, including several interacting flow-related metrics and probability tables, across the range of environmental drivers to demonstrate how we arrived at the final reach-specific indicator states (see SI; Data S1).

Expert judgment was used to assign flow-based or other probabilities to a third group of indicators, algae, aquatic insects, and native fish, in the absence of direct flow-ecology relationships. For example, aquatic insects in each reach were assigned to one of three states: + (many EPT, including insects with 2-yr life cycles), 0 (mostly EPT but univoltine and reduced abundance) and − (some EPT but many tolerant taxa as well). Insect community probability state was a function of three designated drivers (see Fig. 4) of community composition and abundance: (1) channel structure (a function of fine sediment flushing, bed mobilization and bank stabilization), (2) summer base flow magnitude and water temperature above or below 23°C as one combined variable, and (3) algae production (a function of nutrient concentration and scouring flow). For example, a clean and diverse streambed had respective probabilities of producing aquatic insect states −/0/+ of 0.0/0.5/0.5. Note total probability sums to 1.0 across the three states. Adequate summer baseflow combined with cool temperatures generated probabilities for aquatic insect states −/0/+ of 0.0/0.5/0.5. For algae, where future abundance was "about the same as today" insect states −/0/+ were assigned probabilities of 0/1/0. Thus, in a river reach, under a given flow scenario that generates a clean and diverse streambed, adequate and cool baseflow, and about the same amount of algae as today, the conditional probability of an aquatic insect state of 0 is

calculated from the product of the probabilities of the three controlling variables, i.e., $0.5 \times 0.5 \times 1 = 0.25$. Similar reasoning was followed for other response variables lacking suitable empirical monitoring data. For example, probability tables for the impacts of nutrient enrichment (total nitrogen and dissolved phosphorus) and scouring flows on algal biomass were based on general observations of experts in recent years to generate states of − (less than today), 0 (about the same as today), and + (more than today). Native fish states (−−,−, 0, +) were based on expected species richness, abundance, and life stage diversity in response to summer baseflow, temperature, trout predation, aquatic insects, and channel structure (see Shanahan et al. 2014 and SI [Data S1] for further details). Our fish species richness metrics were tailored to the naturally depauperate local assemblage and reduced species richness due to extirpation of specialists more sensitive to flow alterations (e.g., gravel-spawning nest builders, Fausch and Bestgen 1997), but could be easily altered for other geographic areas where fish species richness is higher.

Use of expert judgement, based on research experience and published ecological and hydro-geomorphic principles, is well-established in modeling and decision analysis (von Winterfeldt and Edwards 1986, Otway and von Winterfeldt 1992). Our main effort to reduce uncertainties associated with expert judgement was to assign conservative conditional probabilities, such that only stressor levels in the highest category were coded to cause ecological impairment. This conservatism may lead to less variation in the absolute expected values of each indicator, but the relative differences across the flow scenarios remained robust. While we specified prior distributions for all parameter interactions, we currently lack sufficient empirical data across all flow scenarios and indicators to refine prior distributions. Hence, we proceeded by specifying network linkages (Fig. 4), computing prior distributions from available data, and comparing results for a single flow scenario (recent past) against other scenarios of interest.

The ERM model uses Structural Modeling, Inference, and Learning Engine software running in GeNIe (Graphical Network Interface; Decision Systems Laboratory 2014) and computes conditional probabilities for input data using the general form

$$P(A_i|B) = \frac{P(B|A_i)P(A_i)}{P(B)} = \frac{P(B|A_i)P(A_i)}{\sum_{i=1}^{n} P(B|A_i)P(A_i)}$$

where A and B are possible outcomes and $P(A_i|B)$ is the conditional probability of A_i given B. The eight ERM indicators (model output) measure aspects of ecosystem function and condition and include variables that have regulatory implications, such as Clean Water Act aquatic life criteria, nutrient thresholds, and water temperatures, and biological indicators valued by the community.

Linkages that determined indicator condition were mapped in the final Bayesian network (Fig. 4). Hydrologic drivers including flow magnitude, duration, and frequency influenced physical processes and ecological states directly and interactively and those were altered to create flow regime "scenarios." Flow attributes had both direct and interacting effects on indicator condition. For example, peak flow conditions directly affected algae via scouring, and channel structure via sediment flushing and bed mobilization. In contrast, aquatic insects, native fish, and trout indicators had only interacting links to peak flow attributes, via changes in channel structure, because direct relationships were not available from existing data or reliably inferred from expert judgement. Although hydrology was the primary driver of ecosystem responses, other important factors were also incorporated including water temperature, nutrients and water chemistry, and bank stabilization interacting with flows (Fausch and Bestgen 1997, Dudgeon et al. 2006, Poff 2018).

Hydrologic scenarios

After finalizing the ERM structure, we developed nine hydrologic scenarios as model inputs (Fig. 5; Appendix S1: Table S4). Scenarios characterized their effects on the Poudre River ecosystem (e.g., peak flow frequency, low flow duration) and spanned a spectrum of past to future conditions including

1) three historical scenarios that included historic unaltered regimes (reconstructed native), recent-past altered flows (recent past), and present, continuing flow alteration (present operations;)
2) two future scenarios with reduced water availability due to additional development (additional water development) or climate change (driest climate); and
3) four designed hydrologic scenarios with combinations of base flow magnitude and consistency, and peak flow magnitude, duration, and frequency to achieve specific ecosystem goals. These we referred to as stable base–low peak, high base–moderate peak, dry base–high peak, and stable base–high peak.

Historical and future hydrologic scenario development.— Hydrologic scenarios were based on gage records, diversion withdrawal data, and outputs from models used by city planners and regional water managers. All historical and future scenarios were founded on the recent past scenario, a spatially discretized record of gaged discharges across the study reach. Native and present operations scenarios remove (or add) the effect of existing reservoir and diversion operations in the Poudre River drainage. Together, these models and streamflow gages produced time series of simulated flow at a daily time step (Fig. 5; Appendix S1: Tables S2, S3). To incorporate climate change impacts, the present operations scenario was modified using predictions from global

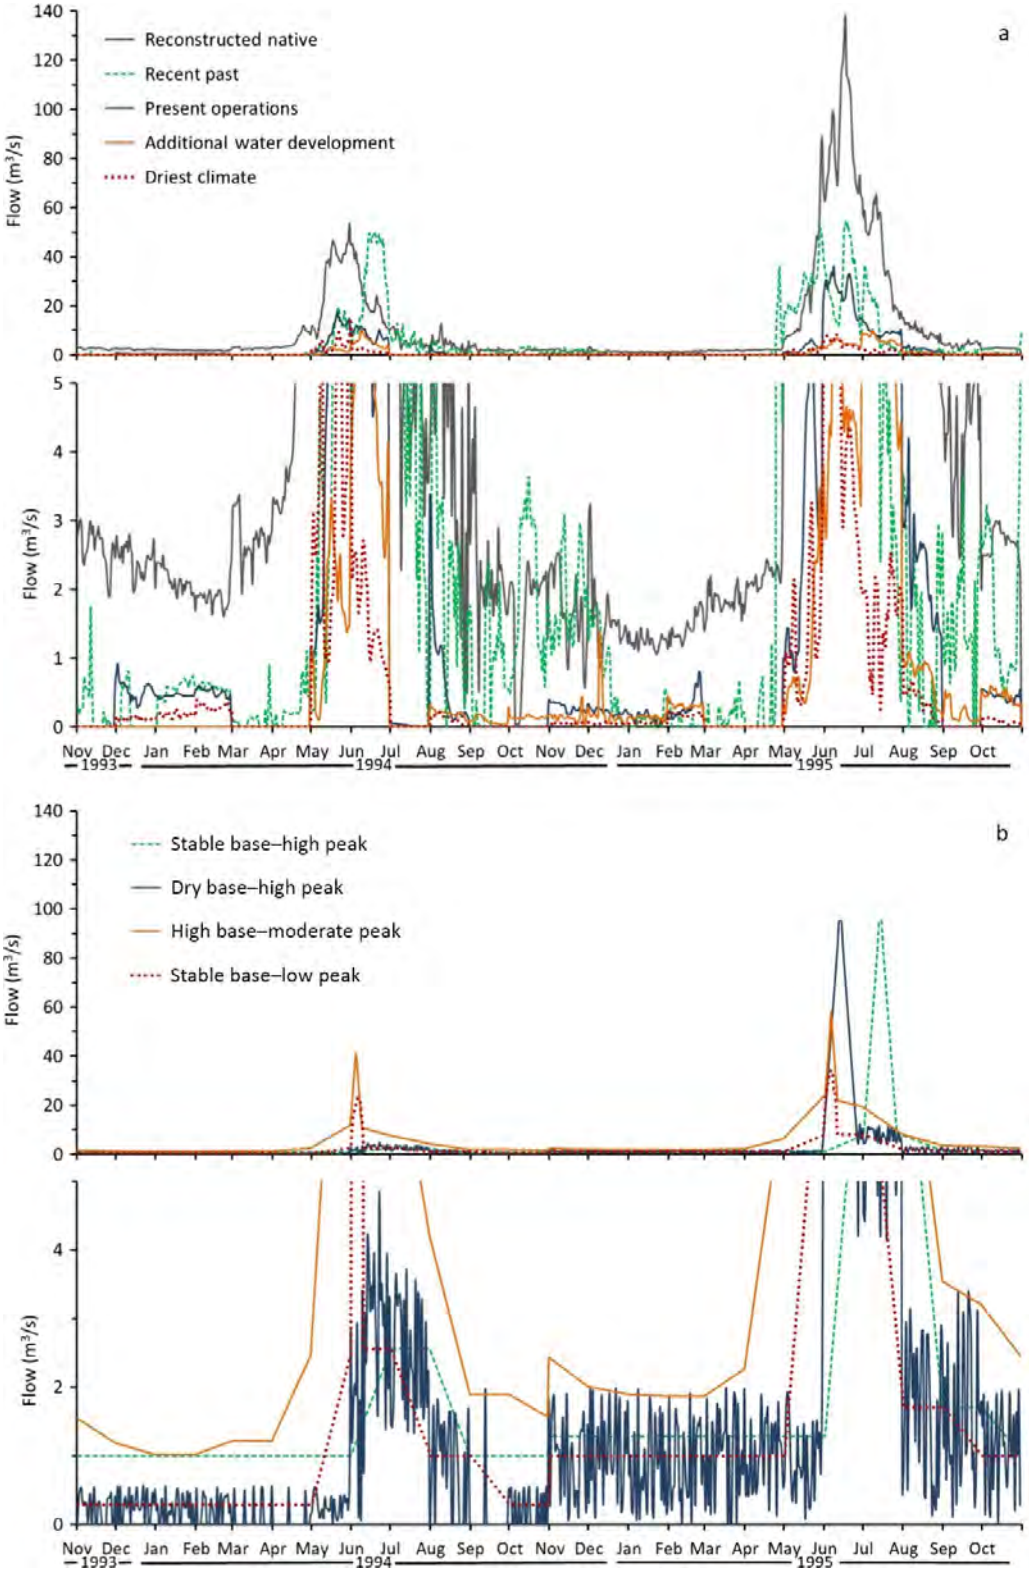

FIG. 5. Dry and wet year hydrographs for the Cache la Poudre River, Fort Collins, Colorado, showing differences in peak (upper) and base (lower panel, expanded for detail) flows for (a) five historical or future flow scenarios and (b) four designed flow scenarios. All are modeled flow scenarios with the exception of the recent past, which is from gage data (U.S. Geological Survey # 06752260).

climate circulation models (Diansky and Volodin 2002) and the Bias Corrected Spatially Downscaled [BCSD], Coupled Model Intercomparison project phase 3 archive (CMIP3, collectively the BCSD-CMIP3) that describes climate-changed hydrologic scenarios for the western United States (Gangopadhyay et al. 2011, U.S. Bureau of Reclamation 2011). Downscaled hydrology data are monthly time series predictions of unit runoff for each circulation model for one-eighth degree (12 × 12 km) latitude-longitude grid cells. Runoff calculations used the CMIP3 scenario with the lowest projected runoff in 2050 (inmcm3_0.1.sresb1) for the grid cell that most overlapped the Poudre River basin, and was the basis for our plausible driest climate scenario. To create the hydrology time series, we first computed the monthly ratio of average runoff under the driest climate scenario to average runoff under current baseline conditions. These ratios were then multiplied by the present operations daily flows to estimate the driest climate hydrologic time series of daily flows used with the ERM.

Designed flow scenario development.—The designed flow scenarios were developed as potential guidelines for water managers with the goal of improving the Poudre River flow regime to achieve certain social-ecological outcomes (Acreman et al. 2014). Designed flow scenarios have combinations of functional characteristics (e.g., Yarnell et al. 2015) that include base flow magnitude and consistency, and peak flow magnitude and duration. Sufficient base flow magnitude supports habitat for fish and aquatic insects, and influences water temperature and nutrient levels, while flow consistency reduces variation due to high diversion extraction or low reservoir releases that presently create disconnected pools and dry reaches detrimental to aquatic life. Although highest magnitude flows depend largely on snowpack levels, proposed water projects would store additional peak flows and further reduce their magnitude and duration, allowing for the possibility of designed flows to achieve downstream ecological targets if reservoir and diversion operators let flows bypass infrastructure. Designed scenarios (e.g., stable base–high peak) also included ascending and descending limb flow rates of change of about 7.1 $m^3 \cdot s^{-1} \cdot d^{-1}$ during the peak runoff period (e.g., Yarnell et al. 2010, 2015, City of Fort Collins 2019); direct effects of limb flows are presumed important but were not modeled. We show two consecutive years of the modeled Poudre River hydrographs for all scenarios (Fig. 5), in consecutive dry (1994) and wet (1995) years, to illustrate differences in base and peak flow magnitude, timing, and variability, among years when snowmelt runoff magnitude differed. Using the ERM relationships between flow and various indicators of river condition, we predicted effects of the four hypothetical designed flow scenarios on Poudre River ecosystem attributes using the same technique as for historical and future flow scenarios.

For each of the three reaches evaluated by the ERM, the ecological response of the eight river indicators under nine hydrologic scenarios was computed as a probability distribution scaled from lower (0) to higher (1) functioning. Each distribution is portrayed as a single mean value, which simplifies data presentation (Table 1; details in Shanahan et al. 2014 and SI). Indicator scores were then plotted (Fig. 6) on a probability scale (0–1) with associated qualitative predictions of condition from lowest (0) to highest (1). For example, channel structure scores were assigned to quartiles of the scale that ranged from an entrenched condition (lowest, score of 0–0.25) to a clean and diverse condition (highest, score 0.76–1). Native fish and trout scores from lowest to highest were assigned relative predictions in four ranked classes (−−,−, 0, +) and lowest to highest riparian indicator scores had relative predictions from minimal to wide areas of inundation, respectively. Indicators with only three categories were similarly assigned, where, for example, aquatic insect predictions ranged from −− (lowest condition, score of 0–0.33) to + (highest condition, score 0.67–1.0). Algae scores represented conditions that were significantly enriched and worse than present conditions (lowest, 0–0.33), similar to current conditions (0.34–0.66), or were significantly improved from present conditions (highest, 0.67–1.0). Differences in indicator scores are appropriately interpreted between flow scenarios in comparative rather than absolute terms as 0–1 scales for each indicator varied with input data and assumptions for each prior distribution.

Results

Modeling showed indicator variable response patterns typical of many flow-regulated systems, but it also revealed lesser-known interactions instructive for ecological understanding and management that varied spatially. Indicator scores were generally highest under the reconstructed native flow regime followed by the two designed flow scenarios with high peaks and the Recent Past regime in the least confined downstream reach (Fig. 6, Table 1). Indicator responses were lowest under future flow scenarios (additional water development or dry climate) in the confined reach. Present operations scenario scores were generally low.

Channel structure and the three Riparian zone indicator response scores were most sensitive (variable) to the array of flow scenarios. Low or zero scores resulted when only low magnitude peak flows were available (e.g., two future scenarios) but channel structure responded strongly to high magnitude flows because key shear stress levels were exceeded (e.g., reconstructed native, two designed flows with high peaks). Among instream biota, algae and trout were most sensitive to flow, responding negatively in the absence of high flows and subsequent impaired channel structure, and positively to presence of higher base flows, especially in winter, and cooler water temperatures in summer. Aquatic insect and native fish scores were the least sensitive to various

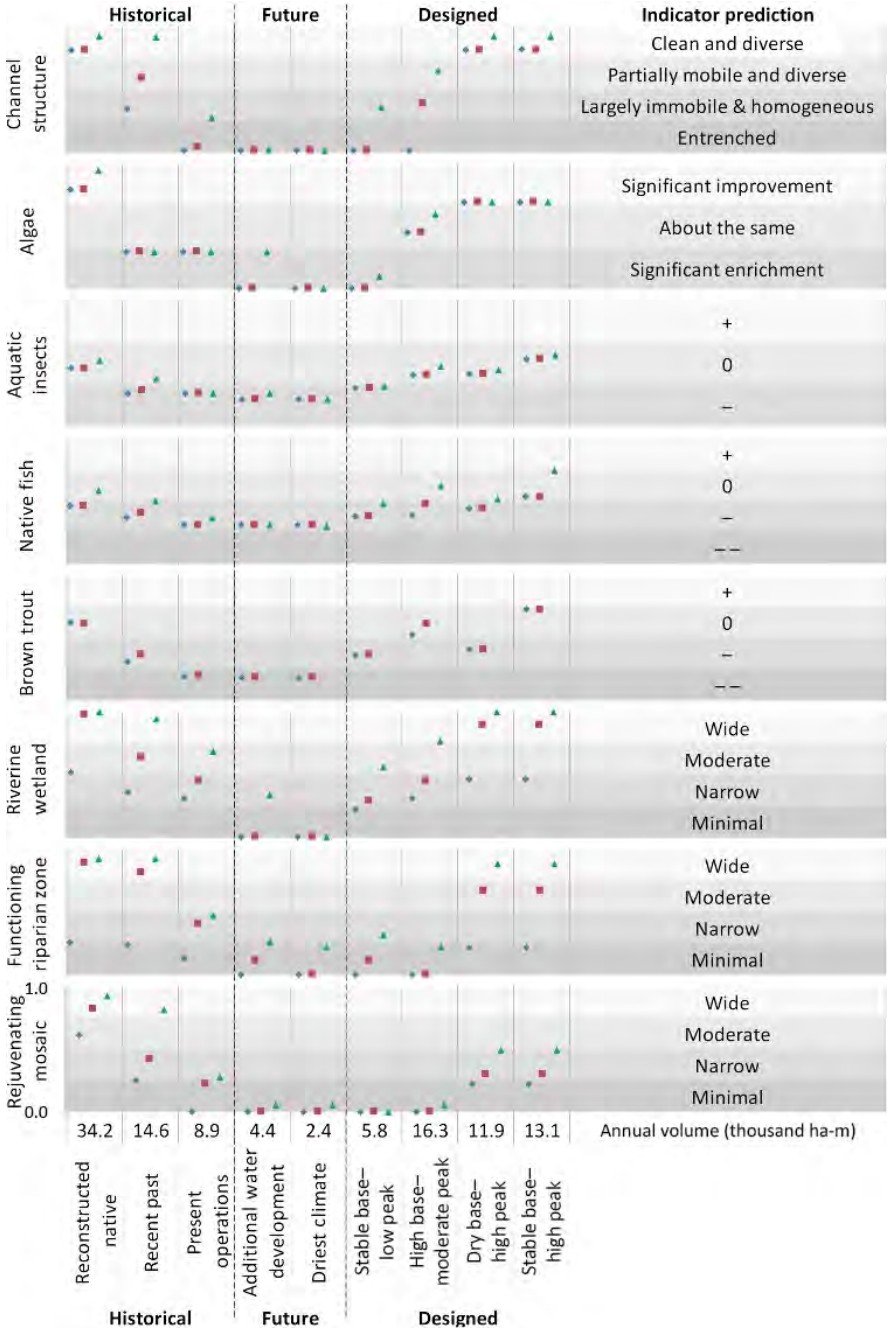

FIG. 6. Indicator predictions for three historical, two future, and four designed hydrologic scenarios for eight indicators of river condition in each of three Poudre River reaches. Each indicator is scaled from 0 to 1, with the four different gray-shaded rows for each indicator showing quartiles of change. From up to downstream, blue diamonds are for the confined reach, red squares for the moderately confined reach, and green triangles for the least confined reach. The annual volume of flow (ha-m) required to achieve each Hydrologic Scenario is portrayed at the bottom of each results column. Scores for river condition indicators for aquatic insects (+, 0, −) and fish (+, 0, −, −−) are arrayed from lowest to highest. No trout scores are presented for the downstream, least confined reach because water was warm, and few trout were present.

scenarios because assigned probabilities for various effects were conservatively estimated, mainly because few specific links to flows and other drivers were apparent (Shanahan et al. 2014). Details for indicator responses to flow scenarios are below.

Channel condition

Channel structure scores declined through the progression from Historical to Future hydrologic scenarios, due to declining peak flows and increased channel

simplification, a pattern generally similar for other indicators. Highest channel structure scores (0.80–0.91) under reconstructed native and some designed scenarios resulted from high magnitude flows for a minimum of three consecutive days that provided sediment flushing, coarse substrate mobilization, channel migration, and increased geomorphic complexity. Alternatively, channel structure score was 0 in high base–moderate peak, additional water development, and driest climate scenarios in confined and moderately confined reaches because flow magnitude was inadequate to mobilize substrate and halt channel simplification.

Flows required for substantive geomorphic work varied spatially along the river corridor. Increasing channel structure scores from upstream confined and moderately confined reaches to the downstream least confined reach reflected increased downstream channel migration and complexity. Increased downstream geomorphic work can be achieved, despite identical simulated river flows, because median sediment size decreased more rapidly than channel gradient from upstream to downstream, so the same peak flow magnitudes increased channel structure scores more downstream.

Instream biota

Algae indicator scores were also highest under reconstructed native and designed hydrologic scenarios with high peak flows (score range 0.70–0.95) but lowest in confined reaches with low peak flows because substrate mobilization and scour were minimal. Identical recent past and present operations scores resulted because flow thresholds that altered channel structure were not achieved.

Aquatic insect scores were highest (0.46–0.57) in high peak and higher base flow scenarios (reconstructed native, stable base–high peak) because those conditions increased taxa richness, life history diversity, and abundance and were lower in confined reaches with low peak flows and low or variable base flows. Native fish indicator scores were higher (0.38–0.75) in scenarios with higher peak flows and consistent base flows (reconstructed native and designed scenarios except stable base–low peak) due to higher taxa richness, life stage diversity, abundance, and channel-structure-related habitat diversity, attributes that were reduced in low peak or variable base flow scenarios. Reasons for reduced score ranges over all flow scenarios and reaches for aquatic insects and native fish were discussed above. Native fish scores in the least confined reach were consistently higher, regardless of hydrologic condition, reflecting greater habitat availability and low abundance of predaceous trout in that warmer reach.

Trout reproduction, abundance, and age-class diversity varied with summer and winter base flow levels, summer water temperatures (higher in low flows), aquatic insect abundance, and channel structure. Thus, highest trout scores (0.40—0.72) resulted from higher peak and consistent base flow scenarios (reconstructed native, high base-moderate peak, and stable base-high peak), which was supported by empirical data that linked trout reproductive success with higher winter base flows. Conversely, trout were negatively affected by low base flows in summer (reduced survival) and winter (reduced reproduction), and elevated summer water temperatures that may reduce dissolved oxygen levels. Effects of lower winter base flows are evident by comparing the dry base-high peak score (0.40) to other designed scenarios with higher base and higher peak flows (score range 0.52–0.72).

Riparian zone

Riparian forests responded positively to high peak flows that saturated soils, mobilized sediment, and created channel movement, and they responded negatively to low flows and bank armoring, especially in confined reaches. Among historical flow regimes, reconstructed native and, to a lesser extent, recent past scenarios elicited the strongest positive response by the rejuvenating mosaic indicator, particularly in the least confined reach (0.94 and 0.83, respectively). Designed hydrologic scenarios with high peak flows showed the greatest improvement over those with moderate or lower peaks. Native riparian tree recruitment was negligible with low peak flows (score range 0.00–0.29) because floodplain connections rarely occurred, even in the least confined reach.

Scenarios with high peak flows (reconstructed native, recent past) produced the highest functional riparian zone scores, especially in the least confined reach (scores = 0.93), similar to riparian wetland scores (0.94–1.00). Wetland development was limited in channel-confined reaches under most flow scenarios (confined reach = 0.00–0.51) because high, steep banks and channel entrenchment prevented river–floodplain connections. Similar to the functional riparian zone, wetlands would increase if bank height were reduced and banks were set back and sloped to allow greater river–floodplain connection and a more continuous moisture gradient. Rejuvenating mosaic scores were lower than the other two riparian vegetation scores under the same flow and reach conditions because flow magnitudes and velocities were insufficient to disturb and scour surfaces needed for seed germination sites.

Annual flow volume required to implement the nine ERM flow scenarios varied widely. For example, annual discharge volume in the reconstructed native scenario was more than twice as high (34,246 ha-m; 278,000 acre-feet, Appendix S1: Table S2) as other scenarios and up to 14× greater than low peak flow scenarios, regardless of base flow characteristics. Notably, when compared with the reconstructed native or recent past scenarios, the stable base–high peak scenario produced comparable or higher indicator scores for most metrics with substantially less water (13,117 ha-m;

106,000 acre-feet, Appendix S1: Table S2). Reach differences for indicators reflected prevalence of overbank flooding, or, of differences in channel structure rather than flows, which were identical across reaches.

All indicators were sensitive to changes in assumptions of driving variables; those with linear or continuous responses were relatively more sensitive than categorical driving variables. For example, increased flows and shear stress caused channel structure change, especially when thresholds for bed particle mobility were exceeded. Channel structure changes then cascade interactively through most instream biological indicators. Categorical variables were less sensitive to flow changes, unless they resulted in response category changes, indicating that additional quantitative data that explicitly linked indicators to flows would improve model performance. Additionally, all indicators have assumptions and thresholds that can be changed, to reflect differing local conditions or addition of new or refined flow regimes, which increases model flexibility and utility.

Discussion

Ecological response model outcomes and important drivers

The integrated ERM for the urban Poudre River demonstrated how the structure and function of the coupled aquatic and riparian ecosystem are strongly shaped by flow and illuminated complex interactions between different taxa and trade-offs with different flow regimes. Thus, this model could provide restoration ecologists and managers with a tool to assess effects of potential future flows to target specific, desired processes or ecosystem attributes. Assuming additional changes from new development or climate change will cause further alterations to the urban Poudre River, the ERM would also allow insights into what specific flow components may need to be "designed" as part of any new infrastructure to help sustain or improve ecological integrity.

Our modeling led to three main observations. First, the conceptual hydrologic calendar and ERM predictions increased our understanding of the complex interactions among flows, bed mobilization, channel structure, and biota (e.g., Fig. 4) that contribute to overall ecosystem condition. Second, specific peak flow magnitudes based on geomorphic measurements and hydraulic modeling were critical for substrate cleansing and mobilization, channel morphology, and overbank flows, with strong subsequent effects on riparian and instream biota. Instream biological indicator scores (aquatic insects, native fish, trout) increased in hydrologic scenarios with greater peak flow magnitudes because of improved channel structure, the physical habitat template of the river, even though those indicators were only interactively linked to peak flows. Implicit is that other important ecological processes and communities not modeled by the ERM, including those supported by ascending or descending limb flows, are maintained. Third, an unexpected model result was that designed flows with high peaks resulted in restoration of impaired processes using about the same Poudre River annual water volume available in the flow-depleted recent past scenario. These complex and interacting Poudre River insights demonstrated by the ERM would not be possible with more traditional flow assessments that evaluate only single variables independent of each other (Brewer et al. 2016, McManamay et al. 2016).

Modeling ERM flow effects indicated how river management could be optimized. For example, high flows had the greatest effects in the least confined channel reach, but all reaches may benefit if flow effects were combined with levee or bank modifications. To this point, lowered banks in the downstream portion of the confined reach promoted successful floodplain cottonwood recruitment in recent higher flow years. Stable base flows most effectively increased instream biological indicators such as trout and aquatic insect scores compared to present conditions because periods of stream desiccation and extreme fluctuations were reduced. Indicator scores in low peak flow scenarios were only about 50% of those with high peaks, demonstrating strong links between geomorphic function and biota.

The importance of natural flow regime components (Poff et al. 1997, Postel and Richter 2003) to a higher-functioning Poudre River ecosystem was illustrated by ERM modeling because peak flows scoured riverbed substrate, increased channel complexity, removed excess algae, and promoted a diverse aquatic insect community that supported fish and likely, other ecosystem components such as terrestrial insectivores (e.g., Baxter et al. 2005). Extreme peak flows that may cause channel incision may not be an issue here because discharge magnitudes in designed flows are relatively low. High flows may also increase the quantity of large wood via channel migration (Yarnell et al. 2010, Wohl et al. 2015, 2019), and river connectivity to floodplain wetlands important to backwater-dependent aquatic organisms. Descending limb flows, although not modeled explicitly, likely modified channel morphology, cued reproduction by fishes and other aquatic organisms, and prepared surfaces needed for native seed germination and seedling growth and survival necessary for perpetuating the ecologically important riparian gallery forest (Mahoney and Rood 1998, Yarnell et al. 2010). Base flows supported fish and aquatic insect reproduction and growth, and successful reproduction by trout until the spring hydrologic cycle begins again.

A changing ecosystem

The Poudre River supports functioning remnants of native riparian and aquatic biota, but this urbanizing ecosystem has undergone significant change over the last 150 yr. Examples include channel modification and simplification, diminished native fish populations, and

limited recruitment of young trees in stands of senescent narrowleaf and plains cottonwood. Native fish only approached the highest indicator condition once (stable base–high peak in the least confined reach 7) because local extinctions are exacerbated by negative modeled interactions with trout (e.g., predation) and habitat changes (e.g., backwater loss) related to simplified channel structure and, presumably, greater upstream river fragmentation and dewatering by diversion dams. Regardless, and specific to the Poudre River system, dynamic model responses of indicators demonstrated ecosystem decline was not inevitable, and that designed flows using existing and proposed infrastructure could lead to improved conditions. The flexible ERM could model ecosystem responses to additional designed Poudre River flow regimes, or be used as a general assessment approach in other altered systems where managers seek to improve ecosystem conditions, after tailoring geographically relevant indicator information for the model.

Similar to other modified arid-land rivers, the Poudre River ecosystem is a spatially variable patchwork of physical conditions with a changing biological composition whose functioning varied even across the relatively short reaches we evaluated. For example, modeling showed confined reaches had reduced ecosystem complexity and indicator scores compared to the least confined downstream reach, which more typified predevelopment conditions (Fig. 2). Thus, modeled ecosystem responses to flow management varied in a spatial context and may better allow practitioners to align restoration prescriptions with reaches most suited for a particular management action. Extreme low flows presently occur in some Poudre River reaches and result in persistent riverbed desiccation especially in winter, effects that are exacerbated by diversion dams that limit upstream recolonization by downstream biota. Effects of management strategies to enhance river connectivity or bank restoration could be modeled in the ERM to evaluate indicator responses and relative costs and benefits of such actions.

We acknowledge that flows discussed here may benefit some nonnative species. For example, anglers fish for nonnative brown trout, because native cutthroat trout (*Oncorhynchus clarkii* [Richardson]) disappeared decades ago due to competition and hybridization with nonnative trout species (Behnke 1992, Bestgen et al. 2019). Further, predaceous trout may have a negative impact on non-salmonid native fishes, creating a challenge in managing for healthy populations of both. We speculate that flows to benefit nonnative trout would also likely benefit native cutthroat trout that once existed here but flow management would do little to restore native trout because they were extirpated by other mechanisms (Behnke 1992).

Unlike the situation with trout, designed flows, and increased channel and floodplain management, may promote native cottonwoods via increased seedling recruitment (Merritt and Poff 2010). This is important because of limited recruitment of young trees to replace old stands of native cottonwoods, keystone species in western stream ecosystems (Merritt and Bateman 2012) that are being replaced by nonnative taxa. Thus, species-specific responses to flow management and the relative ability to favor native taxa over nonnative ones is a planning consideration, and can be modeled with the ERM.

Strengths and limitations of the Ecosystem Response Model

The ERM was constructed to evaluate linked biophysical responses over a range of possible flow futures, with few constraints on what is likely, affordable, or administratively possible. Decision-makers must ultimately weigh stakeholder interests with the ecological, economic, and societal consequences associated with various policy options. Although ERM predictions are not precise in an absolute sense, the power of this modeling approach lies in its integrative and comparative nature. For example, modeling showed that instream biological indicators (e.g., algae, aquatic insects) benefitted from higher and more stable base flows and high peak flows, but stable base flows with low peak flows were only half as effective to increase indicator scores. A nuance was that trout scores in high peak designed scenarios nearly doubled when base flows changed from low to higher levels, reflecting the important seasonal role of flow on reproductive success. Thus, explicit baseflow management to enhance trout in the absence of peak flows would result in only a modest improvement in scores and at the expense of other indicators dependent on high peak flows.

Modeling also showed the strong positive link between channel structure and riparian indicators with peak flow, reflecting gradient (channel structure) or threshold (riparian) effects as peaks declined from historical flow levels. The ERM provides insight into what magnitudes of designed flows would be minimally sufficient to reestablish higher functioning along the river corridor. Thus, designed flows with high peaks would likely enhance channel and riparian functioning, but if peaks came at the expense of higher and more stable base flows, instream biota indicators would decline, demonstrating the utility of the ERM to evaluate flow scenario trade-offs and to explore nuances that may vary seasonally or spatially.

The interactive and data-driven ERM differs from another flow modeling approach, ELOHA, in several ways. ELOHA is mainly a multisite comparative approach intended for use in situations that are data sparse and where scientific capacity to generate detailed knowledge is lacking. Studies more detailed than ELOHA-type analyses are required for highly valued local ecosystems, where the assumption that streamflow alone drives ecological function cannot be accepted, and where other environmental factors such as water

temperature, channel structure, and streambed scour and movement, are important. The ERM for the Poudre River is such a detailed, site-specific model that includes many relationships that are both directly and interactively influenced by flow, directly via flow-linked pathways to indicators, and interactively through indicators. Differences notwithstanding, ERM findings could be placed into an ELOHA-type framework by classifying the Poudre River as a particular flow regime type (in a given geomorphic context) to set expectations for the ecological performance of similar river types.

Indicator response comparisons across a set of diverse and plausible hydrologic scenarios reveal certain futures are likely better than others in terms of a highly functioning ecosystem that provides valued river amenities. Given the altered condition of the present-day Poudre River ecosystem, managers and the public need to consider the vulnerability of the system to further hydrologic alteration and the associated trade-offs. The ERM also illustrates another salient point for river managers to consider: that the same volume of flow can achieve substantially different ecological outcomes, depending on how it is managed.

Thus, the ERM provides a clear framework and useful decision support tool for understanding trade-offs and consequences of various management options on water supply and biota. Indeed, a general, risk-based modeling approach may be more useful than traditional environmental assessments that produce unintegrated measures of resource alteration, especially considering the trajectory of ecosystems under changing environmental conditions including climate warming (Schindler and Hilborn 2015). Application of probabilistic models to other systems will require the system-specific quantification of geomorphic and ecological relationships, which will inform a transparent and science-based process to aid decision-making and clarify the likely trade-offs and consequences of flow management regimes. Modeling approaches that predict ecosystem pathways also allow decision-makers to compare a variety of stakeholder interests and the engineering, ecological, economic, and societal consequences associated with policy options (see Baker et al. 2004).

Futures for flow-altered systems

The ERM analyses confirmed changes in historical Poudre River ecological conditions and indicated additional legacy shifts will occur even if present flow management practices are maintained. Further, ecological changes will be accelerated by additional water development or a drying climate. However, results also indicated carefully managed flows that link key hydro-geomorphic processes with biological responses are likely to enhance ecological functioning of the river ecosystem. Key elements of a designed flow in this and other systems similar to the Poudre River would be peak magnitudes in spring and early summer that meet threshold levels for channel maintenance and riparian vegetation, gradually ascending and descending limb flows, and relatively stable and adequate magnitude base flows, which collectively should improve geomorphic and biological indicators. Because flow requirements differ among biota, maintenance of interannual variability is important to support a more biodiverse ecosystem through time. Although we evaluated only a few designed scenarios, other flow regimes that incorporate additional seasonal or interannual variability in peak or base flows could easily be modeled to better understand those effects.

In any plausible future, the Poudre River will not return to native flows, because annual discharge in the reconstructed native scenario is up to 14× higher than other scenarios. This large gap between natural flow conditions that set the original physical template for the Poudre River and current or future flows suggests that (1) managers of heavily altered river systems may need to set ecological objectives that are not strictly "natural," and (2) designed flows are needed to achieve specific objectives (e.g., Acreman et al. 2014, Brewer et al. 2016, McManamay et al. 2016). The ERM demonstrated that specific Poudre River objectives could be achieved with about one-half the annual discharge of the reconstructed native scenario, if certain flow targets are met. Social and ecological benefits from designed flows in altered systems are most likely to occur if basin-wide flow management is combined with other actions to promote upstream–downstream and channel–floodplain connectivity along the river corridor.

Additional future depletions of Poudre River flows are possible given an existing proposal to store water in a new off-channel reservoir, which will further diminish already reduced peak flow magnitudes and impact river resources. Proposed project mitigation (Northern Colorado Water Conservancy District 2017) has focused on stabilizing base flow, which is needed to reduce present streambed desiccation. Our modeling indicated water levels to accomplish base flow functions in the stable base–high peak scenario was about 1 m^3/s flow (about 35 cubic feet per second), the required level for successful trout reproduction (Bartholow 2010, Appendix S1: Table S2), and improved functioning of other indicators. However, the proposed base flow would meet this threshold on average only 50% of years and would not benefit river resources downstream of the city because flows will be diverted.

Peak flow frequencies and magnitudes proposed are also inadequate to maintain channel condition and biota because a 3-d peak bypass flow is projected to occur in only 43% of years (Northern Colorado Water Conservancy District 2017; data *available online*).[12] Further, mean peak Poudre River flow magnitudes are unlikely to reach even the 31 m^3/s estimated for the relatively low present operations scenario in most years. As modeled

[12] http://www.northernwater.org/docs/NISP/MapsDocuments/2017FWMEPFinal.pdf

by the ERM and predicted by fundamental principles of river science (Poff et al. 1997, Wohl et al. 2015), changes from proposed additional water development would essentially ensure a general and long-term decline in Poudre River aquatic and riparian ecosystem functions. Thus, the best possibility for maintaining or improving Poudre River ecological conditions with the proposed off-channel storage is designed peak flows that bypass the newly proposed storage reservoir for a minimum of three consecutive days with the predicted highest magnitude flows each year. This scenario also ensures the natural interannual variability in flows needed to sustain ecosystem functioning, effects of which are seen by comparing ERM outcomes of managed scenarios with different peak flow levels.

Ideally, the frequency and magnitude of peak flows in flow-depleted rivers could be partially restored to more closely approximate natural flows, which here are those in the reconstructed native scenario (i.e., ≥3-d peak flows in more than 50% of years that reach 94.9 m^3/s at Fort Collins, to provide the flow magnitude and duration needed for channel maintenance (Andrews and Nankervis 1995, Emmett and Wolman 2001)). Although existing storage reservoirs and diversions have substantially reduced Poudre River peak flows, our analyses show that the estimated "deficit" in peak flow volume and duration could be met with bypasses from existing storage facilities or diversions in the Poudre River basin, which in real time would require adequate flow forecasting. Other studies that have implemented designed flows (Kiernan et al. 2012) or modeled them (Chen and Olden 2017, Sabo et al. 2017) show it is feasible to balance existing human demands while provisioning key ecosystem targets. Adaptive management will be needed to ensure flow scenarios support desired outcomes. Additional details regarding the high flow mitigation specific to the Poudre River are elsewhere (Appendix S2).

As stressors on over-allocated river ecosystems increase from human water demands and climate change, modeling approaches that predict future ecosystem responses to water development and management will play an increasingly important role in informing public debate and choices about management of these resources (Baker et al. 2004, California State Water Resources Control Board. 2017). Ecosystem-based models such as the ERM can identify strategies to achieve firm targets to assist with rehabilitation or mitigation plans in water development scenarios. Unfortunately, no policy requires that integrated, holistic, ecosystem-scale impacts be assessed before new water projects are approved. Rather, requirements for assessing "impact" under NEPA are satisfied when analyses are framed only in traditional single-variable models. Thus, even when river engineers and other scientists not associated with water development interests construct holistic models of "impact" (e.g., the ERM), there is no clear pathway to having those substantively considered in project development, much less adopted. Another fundamental problem with the traditional NEPA-driven "environmental impact" approach is failure to consider ecosystem functions and societal values on par with the economic factors that largely dictate proposed alternatives for development. Typically, impacts of the preferred project alternative are evaluated with a few single-factor analyses that are portrayed as causing minimal environmental alteration. Joint consideration of both long-term ecological issues and short-term economic gain at the project proposal stage may aid development of more environmentally sustainable alternatives, especially in light of new uncertainties posed by climate change (see Poff et al. 2016). This would promote more robust science and more transparent trade-off analyses of alternative development options needed to support more rational societal decisions about river management in a complex and uncertain future.

Acknowledgments

We appreciate the contributions of J. Stokes, B. Anderson, the Northern Colorado Water Conservancy District staff, and especially J. Shanahan for assistance throughout. Comments from S. Brewer, J. Friedman, S. Yarnell, K. Zelasko, and an anonymous reviewer improved the manuscript. M. Haworth assisted with construction of Fig. 1. J. Shanahan, B. Bledsoe, and N. L. Poff conceived the study. D. Baker and M. Lorie conducted modeling. K. Bestgen, B. Kondratieff, B. Bledsoe, J. Shanahan, D. Merritt, and N. L. Poff provided data. K. Bestgen led manuscript writing but all authors contributed.

STATE of the POUDRE

A River Health Assessment

City of Fort Collins

BCC 08/17/20

NISP

Executive Summary

The purpose of this first State of the Poudre River (SOPR) is to provide a description of the current health of the Cache la Poudre River (Poudre) from approximately Gateway Natural Area to I-25. The Poudre is a complex natural system that has been altered by nearly two centuries of human influence. This has resulted in dramatic changes to the physical structure of the river, water quantity and quality, floodplain, forests, and wildlife communities. The human footprint continues to expand, placing additional pressure (or stresses) on the river ecosystem and the natural processes that sustain it. This river health assessment provides the City of Fort Collins with a new tool to track trends and benchmark progress towards its vision of sustaining a healthy and resilient Cache la Poudre River.

While the Poudre flows 126 miles from its headwaters to its confluence with the South Platte near Greeley this study focuses on a 24-mile reach from the lower canyon through Fort Collins. The study area was divided into four zones (Canyon, Rural, Urban, and Plains) and further into 18 study reaches based on natural changes on the landscape and human influences.

Overall Grade: For the 24-mile study area the Poudre River received an overall grade of C. This grade indicates the even though the Poudre has been altered and degraded by a suite of local and system wide stresses that impair its health, it continues to support basic elements of a functioning river ecosystem.

The framework for this baseline assessment includes nine indicators of river health which are informed by 25 indicator-specific metrics. Collectively these provide a thorough evaluation of how well the system is functioning. Metrics grades are developed by collecting and incorporating many types of data, which were then translated into an A-F grading system. Indicator and metric numerical scores and their corresponding letter grades were calibrated to categorical definitions relating to degree of functionality or impairment.

Recommended ranges developed for each metric (as established in the River Health Assessment Framework, City of Fort Collins, 2015) and were developed based on the City's concept of working towards a functioning river ecosystem. The recommended ranges consider the contemporary real-world context and reasonable expectations for future change and the potential for improvement. They should, however, be used as a guide and aspiration rather than a directive. Also, when interpreting results for a comprehensive scientific assessment such as this, it is important to consider that uncertainty and variability exists across scientific disciplines, data sources, and river reaches. The methods and grading guidelines provide an explicit description of the analytical approaches used and can help the reader understand this variability.

This report is structured to allow the reader to understand the project approach (Sections 1 and 2) followed by identification of potential influences, or stressors, on river health in Section 3. The health assessment scores (Section 4) reveal the ramifications these anthropogenic stressors are having on ecosystem condition. Results indicate there is considerable variability across aspects of river health as scores vary widely (from A to F) at smallest unit of measurement (metrics scores by reach). In Section 5, the focus shifts to an overview of river health, describing the link between stressors and degree and type of impairment for each of the four zones. Poudre River health indicator grades for each zone are

compared to the ranges recommended in the City's Poudre River Health Assessment Framework (2015)—to highlight areas where there is the greatest gap between the City's goals for the river and today's conditions. This section also includes an analysis of the causes of impairment and explores which problems are tractable to practical solutions. Section 6 looks toward the potential future applications and improvements for the project.

Key findings by topic

- The Poudre is characterized by major changes in flow volumes and timing. Reductions have significantly altered peak and base flows, the effects which are exacerbated the further one travels downstream. Diversions also cause unnatural fluctuations in flow volume, which likely affects critical habitat and reproductive needs of fish and insects in the river.

- The river channel has seen drastic changes over the past two centuries causing widespread fundamental alterations to the ecosystem. The river used to meander across the floodplain. Forcing it into a single, permanent path has disrupted various processes dependent on natural river movement including the regeneration of riparian forests, the movement and balance of sediment, the river's resilience to large floods, and other events like wildfires in the upper watershed. However, with today's land uses, there is a need to protect infrastructure in the floodplain. Understanding this new physical dynamic and its relationship with extreme flow events is central to successful management for river health.

- Water quality in the Poudre is quite good, despite the presence of some stresses, and is supported by the City's commitment to manage stormwater runoff and meet regulatory requirements for treated wastewater effluent. The City and others closely track water quality, implementing quick action if undesirable changes are detected.

- While non-native trout are thriving in Poudre's cooler waters (generally upstream from College Avenue) the populations of native fish are in sharp decline. These declines are most likely due to fragmented habitat and extended periods of extremely low base flows. Other stresses likely influencing fishery health include rapid fluctuation of flows, non-native predatory fish and altered water temperatures.

- The riparian corridor has experienced a system-wide disconnect between the river and its floodplain. In many places riverside forests form only a narrow band that hugs the river banks providing little support for overall river health. However, where the riparian corridor is connected to the river there are pockets of healthy forests including a mosaic of diverse habitats, which are ideal for supporting wildlife. Restoring the river-floodplain connection and active management of aggressive non-native trees is making a positive difference across City-owned floodplain properties.

Zone Highlights

Canyon zone: B- (Munroe tunnel, above Gateway Natural Area, to the canyon mouth)

Through the Canyon zone the river and riparian corridor are confined by canyon walls. Highway 14 further limits the river's space and ability to mitigate large floods. Here the river supports aquatic life, a narrow riparian forest, and floodplain, but this zone marks the beginning of an approximately 20-mile reach of river that is heavily impacted by multiple diversions which begin to reduce flows and fragment aquatic habitat. The upstream forested watershed provides the City and surrounding communities with a reliable and high quality drinking water source, but in the lower Canyon zone warming water temperatures emerge as a potential concern for aquatic life.

Rural zone: C (Canyon mouth to just below Overland Road)

As the Poudre leaves the canyon the river has its first opportunity to connect to a wider floodplain, but impacts from berms, armored banks, and channelization disconnect the river from its floodplain. Native cottonwoods dominate many riverside forests; however, encroachment from agricultural lands affects the health of the vegetation. Cooler waters released from Horsetooth Reservoir lower water temperature in this zone. The impact of multiple large water diversions severely alters peak and base (low) flows.

Urban zone: C (just below Overland road to Timberline Road)

Gravel pits and associated berms affect the river's ability to access the floodplain on the upstream end of the Urban zone, while encroachment from roads and development through the City have impacted the diversity and extent of the riverside forests and habitats. Nevertheless, pockets of excellent riverside forests exist (near Shields Street) where high spring flows have access to the floodplain. The river once formed multiple braided channels increasing the system's capacity to mitigate large floods, but now as a single, confined channel it has reduced resilience to flooding. Diversion dams and the lack of large wood in the channel negatively impact habitat for aquatic insects and fish. While introduced non-native trout appear to be doing well, a major concern is the local loss of native fish.

Plains zone: C (Timberline Road to I-25)

As the river flows through large areas of land managed as conserved open lands river health improves slightly in the Plains zone. Yet the legacy of land use and water diversions continues to have a significant influence on river health. Diminished peak flows and significantly impacted base flows have created a smaller-than-natural river channel that is frequently disconnected from its floodplain. Low numbers and diversity of native fish are a major concern, but fish passage structures allow for better aquatic habitat connectivity.

So what?

A "B" grade for river health is desired to fulfill the City's vision for a healthy and resilient river. This holistic and science-based river assessment can help the City evaluate operational, management, and policy options for preserving or enhancing the river's health. This assessment can also serve as a benchmark for monitoring river health and changes in the future. Broader communication and engagement of diverse Poudre River stakeholders can strengthen our ability to manage for a healthy river now and in the future.

This report presents and discusses the comprehensive set of projects findings. Other project components (a summary report card and online mapping tool) are available at: www.fcgov.com/poudrereportcard.

Glossary

Alluvial channel – a stream or river channel with soft bed and banks that maintains form through dynamic equilibrium between the forces of erosion and deposition. (See **threshold channel**.)

Armoring (bed) – the formation of a more scour-resistant layer of large particles on the surface of a river bed.

Armoring (channel) – the application of resistant materials on a river bed or banks for to reduce scour and erosion.

Augmentation (of flow) – addition of water to a system. (See **depletion**.)

Avulsion – the sudden change of river location. (See **migration**.)

Benthic macroinvertebrates – often referred to in this report simply as "aquatic insects", benthic macroinvertebrates refers to insects and other small invertebrate (without backbone) organisms that live in or on the river bed.

Channel maintenance flows: Flows large enough to initiate scour and deposition processes, including associated channel migration, which in turn maintain river conveyance capacity by scouring encroaching vegetation within the bankfull channel.

Channelization – mechanical alteration of a river or stream that confines flow within a single course. Often times these actions can be combined with planform straightening.

Depletion (of flow) – removal of water from a system (See **augmentation**.)

Embeddedness – the degree to which interstitial spaces between river substrate particles are filled with fine sediment. (See **interstitial space.**)

Encroachment – the intrusion of artificial structure, development, or land use on the floodplain or riparian zone. A second use of this word is when vegetation encroaches or moves into the existing active river channel.

Entrenchment – the degree to which river flows are vertically contained within a channel.

Flushing – the mobilization of sediment particles from the river bed substrate matrix by the physical force (referred to as shear stress) of moving water.

Flushing flows- the mobilization of median bed size material to support habitat and life cycle needs of aquatic insects and fish that rely on clean interstitial space.

Geomorphic (geomorphological) – relating to the form of the land or topography.

Interstitial space – the open space between particles, here referring specifically to open spaces in the river bed between substrate particles.

Mainstem – the principal or dominating stream or river in a drainage, in this case, it refers to the Cache la Poudre River.

Migration – the gradual change of river location. (See **avulsion**.)

Reach – a discrete segment of river between two points. In this study, 18 discrete reaches are defined for the purpose of assessment.

Riparian zone – the area between a stream and adjacent upland that whose vegetation and hydrology depend on the stream**.**

Threshold channel – a stream or river channel with hard bed and banks that maintains form by resisting erosion. (See **alluvial channel**.)

Metric definitions

The definitions provided below are intended to explain each metric concept in general terms. Definitions specific to this study for each metric are presented in Appendix A. Metrics are listed per the structure of the Poudre River Health Assessment Framework.

Peak flows occur when the river is at its highest flow; usually in the late spring or early summer.

Base flows are the low flows that occur during drier times of the year – diversions can cause base flow-like conditions at uncharacteristic times of the year.

Rate of change of flow describes how fast diversions lower or increase the quantity of water in the river channel.

Land erosion considers the amount of sediment produced in the watershed by hillslope processes and land uses resulting in exposed soils.

Channel erosion includes sediment production caused by channel erosion along the mainstem and its tributaries.

Sediment transport represents the ability of the river to export sediment from a reach in balance with what is coming in.

Water temperature compares the monitored temperature of water in the river with applicable water quality standards.

Nutrients examines overall load of water-quality impairing elements and compounds, most commonly involving nitrogen and/or phosphorous.

pH of water is a measure of its acidity or alkalinity.

Dissolved oxygen content is the density of oxygen in the river's waters, measured in milligrams/liter.

Floodplain extent is the amount of 5-year floodplain remaining in the SOPR riparian zone.

Vegetation structure and complexity considers the composition and condition of four habitat strata, canopy, sub-canopy, shrub, and herbaceous, along with patchiness and interspersion, and native forest regeneration.

Habitat connectivity examines the amount of natural or semi-natural habitat in the SOPR riparian zone and the ease with which animals can move through the riparian corridor.

Contributing area evaluates the ability of the area within 200m of the SOPR riparian zone to support or degrade river health, as a result of land use and land cover

Planform refers to the 'bird's eye' view of the river and describes the degree of branching and sinuosity.

Channel dimension focuses on the cross-sectional shape of the channel which can be altered by the processes of degradation, enlargement, and widening.

Channel profile is the downstream gradient or slope of a river, including any abrupt drops caused by dams or other grade control structures.

Dynamic equilibrium is the long-term (decadal) tendency for a river to maintain its form or character under a characteristic flow and sediment regime.

Channel recovery describes the ability of a river system to rapidly recover from changes arising from singular extreme events or disturbance (*e.g*., floods, fires, landslides) in an acceptable length of time.

Coarse-scale physical structure includes the characteristic diversity of different water velocity conditions (fast versus still water), depth, and physical cover such as structural elements (*e.g*., large wood jams or rocks), overhanging banks, and vegetation for the selected reference condition.

Fine-scale physical structure evaluates the amount and diversity of microhabitats within the reach, primarily bed materials and algae.

Aquatic insects considers the abundance of indicator taxa against desired amounts.

Aquatic habitat connectivity is the degree to which a zone is segmented by cross-channel structures, usually related to diversions.

Acronyms

RHAF	River Health Assessment Framework
SOPR	State of the Poudre River

Table of Contents

1 Introduction and overview

1.1 Introduction

This State of the Poudre River (SOPR) report is an ecological assessment of current-day river health, designed to represent a wide range of legacy and modern-day influences. A healthy Poudre River corridor offers many important social, environmental and economic benefits to the City of Fort Collins. Maintaining river health is directly addressed in City's guiding strategic document, Plan Fort Collins, which states that the City will work towards "*…sustaining a healthy and resilient Cache la Poudre River*" (City of Fort Collins, 2010). The methods used in this river health assessment are detailed in the Fort Collins River Health Assessment Framework (RHAF) (City of Fort Collins, 2015).

The SOPR details the results of the first health assessment for the Poudre River. Two related products provide other avenues for audiences to engage with the results from this project. The River Health Report Card is a succinct, colorful summary of key findings and river health grades. An online mapping tool allows audiences to explore the assessment results at various spatial scales and on specific topics of interest. All elements of this project are available at fcgov.com/poudrereportcard.

The Cache la Poudre River (Poudre) runs approximately 126 miles from its headwaters in Rocky Mountain National Park to its confluence with the South Platte near Greeley. The study area of this assessment is limited to the section of river that most directly influences Fort Collins and extends from the City's water supply intake— near Gateway Natural Area in the lower Poudre Canyon — to Interstate-25.

1.2 Why assess river health?

The Poudre and its riparian floodplain habitat are a naturally complex system that have been altered by nearly two centuries of modern human use, resulting in dramatic changes to water quantity and quality, physical structure of the river and floodplain, riverside forests, and wildlife communities. Today, our human footprint continues to expand, placing added pressure on the river ecosystem and the natural processes that sustain it.

The City, across its many departments and divisions, is involved in a variety of projects and planning efforts that affect the river in many ways. This work is often aimed at mitigating specific, known stresses or enhancing particular benefits, also known as *watershed services*. Watershed services include the provision of consistent and clean water supplies, flood mitigation, fish and wildlife habitat, and diverse recreational opportunities (Figure 1.1).

The task of understanding, managing, and communicating the health of this complex system becomes increasingly important as the pressures that threaten its health and function also continue to grow. However, historically, there has not been a centralized or structured way to measure the collective impact of the City's efforts on the overall health of the river. To address this need, the City of Fort Collins Natural Areas and Utilities Watershed Program have developed this first holistic ecological assessment

of Poudre River health. It will provide the City with a comprehensive reflection of ecosystem health, enabling the City to benchmark progress towards achieving and sustaining river health in the broader context of sustaining watershed services.

By integrating hydrological, chemical, geomorphic (physical), and biological data into a holistic assessment of river health, this project provides a common platform for tracking river health in meaningful and measureable ways. A useful aspect of the SOPR is that it is easy to interpret at all levels of technical experience. It incorporates a wide range of information into a river health grades and uses the common A through F academic-type grading system. To track changes in river health over time, the SOPR assessment should be conducted periodically (every 3 to 5 years).

This accessible communication platform can expand stakeholder involvement and enhance dialogue around river management. Engagement of diverse interdepartmental and regional stakeholder groups can strengthen our collective efforts toward the goal of managing for a healthy Poudre River and illuminate opportunities to improve watershed services

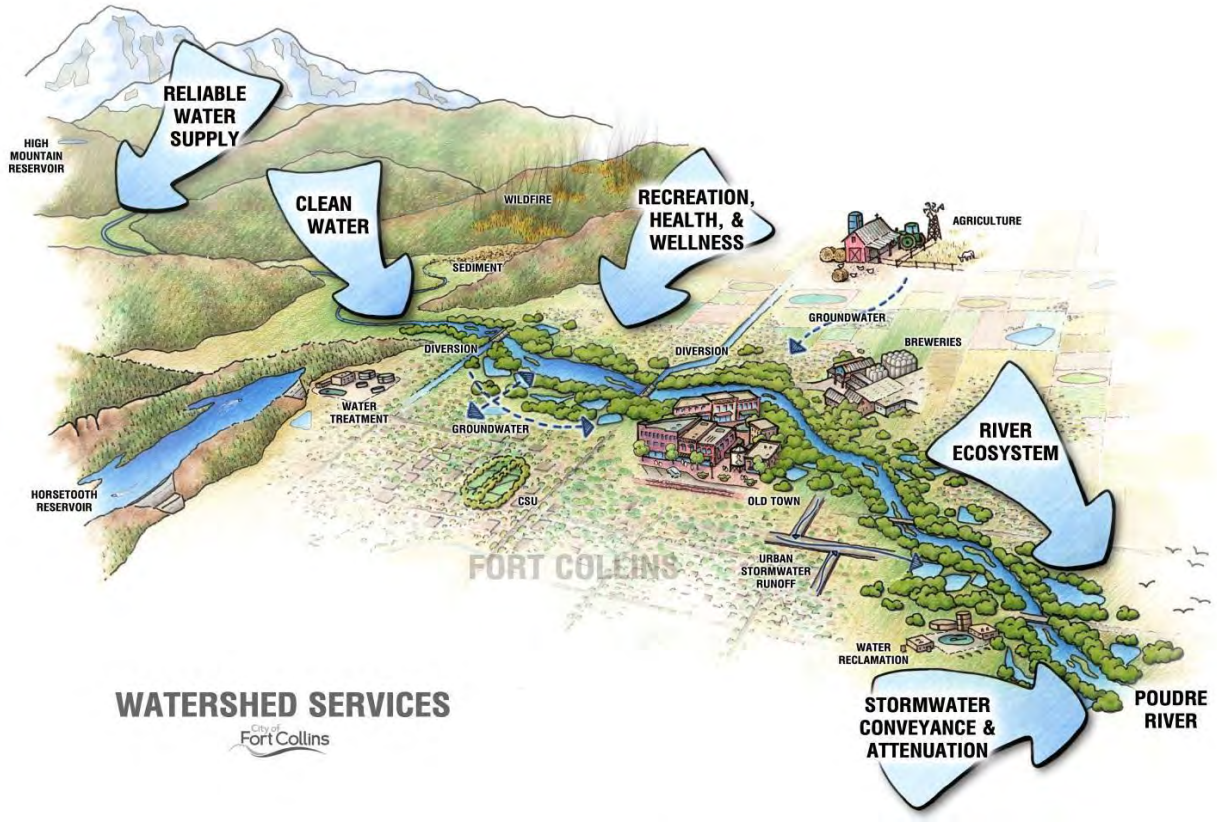

Figure 1.1: The watershed services provided by the Poudre River include consistent and clean water supplies, flood mitigation, fish and wildlife habitat, and recreational opportunities.

1.3 Community benefits of a healthy and resilient river

Figure 1.2: A healthy and resilient river is a river that sustains basics functions (such as water quality) during the years with average precipitation and also provides protective benefits such as (floodwater attenuation and infrastructure protection) during extreme wet or dry years.

The *health* of the river system is a reflection of its ability to perform its normal suite of functions, thereby providing the benefits our community values and depends upon (Figure 1.2). *Resilience* of the Poudre River is interpreted from two perspectives in this assessment:

- As a component of long-term river health, resilience is the ability of the system to maintain or regain its fundamental characteristics and functions after a major disturbance such as an extreme flood, drought, or fire.
- From the human point of view, resilience is the ability of communities to keep functioning during and after major disturbance or natural disasters. In this sense, resilient systems are those where human safety and infrastructure are not threatened by the river's response to disturbance.

The 2013 flood event provided excellent examples of river and community resilience across the Colorado Front Range. In general, reaches where rivers had ample natural floodplain capacity and room to move and adjust recovered quickly after the floods, and damage was minimal. Reaches where floodplain development and infrastructure relied on artificial stabilization tended to have the greatest river health impacts and the most infrastructure damage.

2 Methods

2.1 River health is measured through function

In taking a functional approach to understanding river health, the underlying question is not how the ecosystem looks, but rather, how well the system is functioning. A functional assessment conveys information about the condition of, and inter-dependencies between, many different components of the river ecosystem. It affords the advantage of not only revealing the current stressors (human impacts- past or present- that impair river health), but also how management actions and other changes may affect the future health and resilience of the river. The methods used herein are adapted from the Functional Assessment of Colorado Streams (FACStream) protocol (Beardsley, et al. 2015) and are fully documented in the City's "*River Health Assessment Framework" (*City of Fort Collins, 2015).

The River Health Assessment Framework (RHAF) is structured around ***indicators*** of river health which are informed by indicator-specific ***metrics***, to provide a thorough evaluation of how well the system is functioning. Indicator and metric scores and their corresponding grades were calibrated to categorical definitions relating to the degree of functioning or impairment (Table 2.1). The grade ranges take into consideration the conditions necessary to support a functioning river ecosystem in the contemporary context with reasonable expectations for future change and potential improvement. An A grade represents the highest level of functionality and F the lowest.

Table 2.1: General guidelines used for calibrating indicator and metric grades in the Poudre River Health Assessment Framework.

Grade	Score	Descriptor	Explanation
A	90 – 100	Reference standard	Condition of the indicator or metric is self-sustaining and supports functional characteristics appropriate to sustain river health. Little or no management is needed to sustain and protect this level of function, given the minimal from the modern landscape.
B	80 – 89	Highly functional	Condition maintains essential qualities that support a high level of function, but there is some influence of stressors at a detectable, yet minor, level. Requires limited management to sustain and protect against stressors.
C	70 - 79	Functional	Condition is altered by stressors that substantially impair functionality, basic natural river functions are still sustained. Periodic, and at times intensive, management is required maintain the river's functional role.
D	60 - 69	Functionally impaired	Condition is severely altered by stressors that impair basic natural river functions and the overall health of the river. Active management is required to maintain the river's functional role.
F	50 - 59	Non-functional	Condition is profoundly impaired by massive or overwhelming stressors that render it incapable of supporting basic natural river functions or it is otherwise unable to sustain biological river communities.

These reference definitions provide direction and the foundation for development of metric specific grading guidelines which are presented in full in Appendix A.

The final step in development of the RHAF was to determine a recommended range for each metric that, if achieved, would contribute to an overall healthy and functioning system. These recommended ranges are reproduced in Section 5 of this report to provide context that will convey a picture of today's river conditions compared to conditions needed for a healthy river. It is important to note that while these recommended ranges represent a goal to work *towards*, they are not an edict or mandate for the City. Initiatives aimed at improving any specific metric must be considered within the context of other City goals, as well as legal and jurisdictional limitations. River health goals can at times or in specific places be in conflict with other City goals which may take priority, particularly for the provision of essential services such as drinking water, public safety, and protection of infrastructure.

2.2 Assessment framework

The framework consists of nine indicators and 25 metrics (Table 2.2). Some refinements of the original Poudre RHAF were implemented during this assessment in response to data availability and field trials (these changes are outlined in Appendix B). This SOPR baseline assessment is the first application of the Poudre RHAF and it represents a snapshot of the river's health during the 2015 and 2016 period.

Table 2.2: Summary of indicators and metrics included in the State of the Poudre River baseline assessment.

Indicator	Metrics
Flow regime	Peak flow, base flow, rate of change
Sediment regime	Land erosion, channel erosion, continuity
Water quality	Temperature, pH, nutrients, dissolved oxygen
Floodplain connectivity	Floodplain extent
Riparian condition	Vegetation structure, habitat connectivity, contributing area
River form	Planform, dimension, profile
Resilience	Dynamic equilibrium, recovery potential
Physical structure	Coarse-scale structure, fine-scale structure
Aquatic life	Aquatic insects, aquatic habitat connectivity, native fish, trout

The RHAF indicators serve as the framework to organize information from river-related scientific disciplines and to make it easier to understand the ramifications for river health. The metrics are the backbone of the RHAF and represent aspects of the river ecosystem which can be practically measured. They are defined in the RHAF and the grading guidelines for each metric are provided in Appendix A; an abbreviated list of metric definitions was also included in the glossary as a quick reference to assist readers throughout the rest of this document.

Figure 2.1: Team member and geomorphologist, Johannes Beeby, conducts a rapid assessment of the river form, resilience and physical structure metrics.

2.3 Study area

The SOPR study area encompasses the Poudre River and its associated riparian area from just upstream of the Munroe Diversion (above Gateway Natural Area in the Poudre canyon) to Interstate 25. The river varies greatly through the study area with a range of geologic and ecological settings and different types of human influence. To account for this variability and meaningfully convey the state of the Poudre River, the study area was divided into four zones: Canyon, Rural, Urban, and Plains. These four zones were further subdivided into a total of 18 reaches to define relatively homogenous assessment units (Figures 2.2. 2.3, Table 2.3)

As a natural ecological transition zone, the changes that occur to the river through the SOPR study area are extensive and even greater changes are brought by anthropogenic impacts (Figure 2.3). The Canyon zone is relatively steep (average slope of 0.65%) and forested, and the river corridor is geologically confined. It is mostly unaltered except for several diversion dams and Colorado Highway 14, which parallels the river. The Rural zone, stretching from the canyon mouth to Overland Trail, is on the upper piedmont which remains relatively steep (average slope of 0.55%). Here, the floodplain opens up and the river is mostly unconfined, except for a few points where it flows through water gaps in the hogbacks. Rural-land uses dominate the landscape, but some higher-density residential development is situated adjacent to the river in the Town of Laporte and diversion dams segment the river.

In the Urban zone, the river flows through Fort Collins where there is a high level of residential, commercial, and industrial development, along with many bridges and diversion dams. The river is less steep in this zone (with an average slope of 0.40%) and is naturally unconfined. However, floodplain encroachment, channelization, and artificial stabilization have confined the river through most of this zone. Below Fort Collins, the Poudre exits the piedmont to flow into the plains. Average river slope in the Plains zone is 0.27%, but there is an abrupt change from 0.35% to 0.15% at the toe of the piedmont near the Environmental Learning Center (ELC). The natural geologic channel confinements in this zone are few, and the historic valley bottom would have been at its widest here. Even though the dominant land uses on the plains are rural and industrial (mostly gravel mining), the floodplain extent is tightly confined by artificial features such as berms, roads, and bridges.

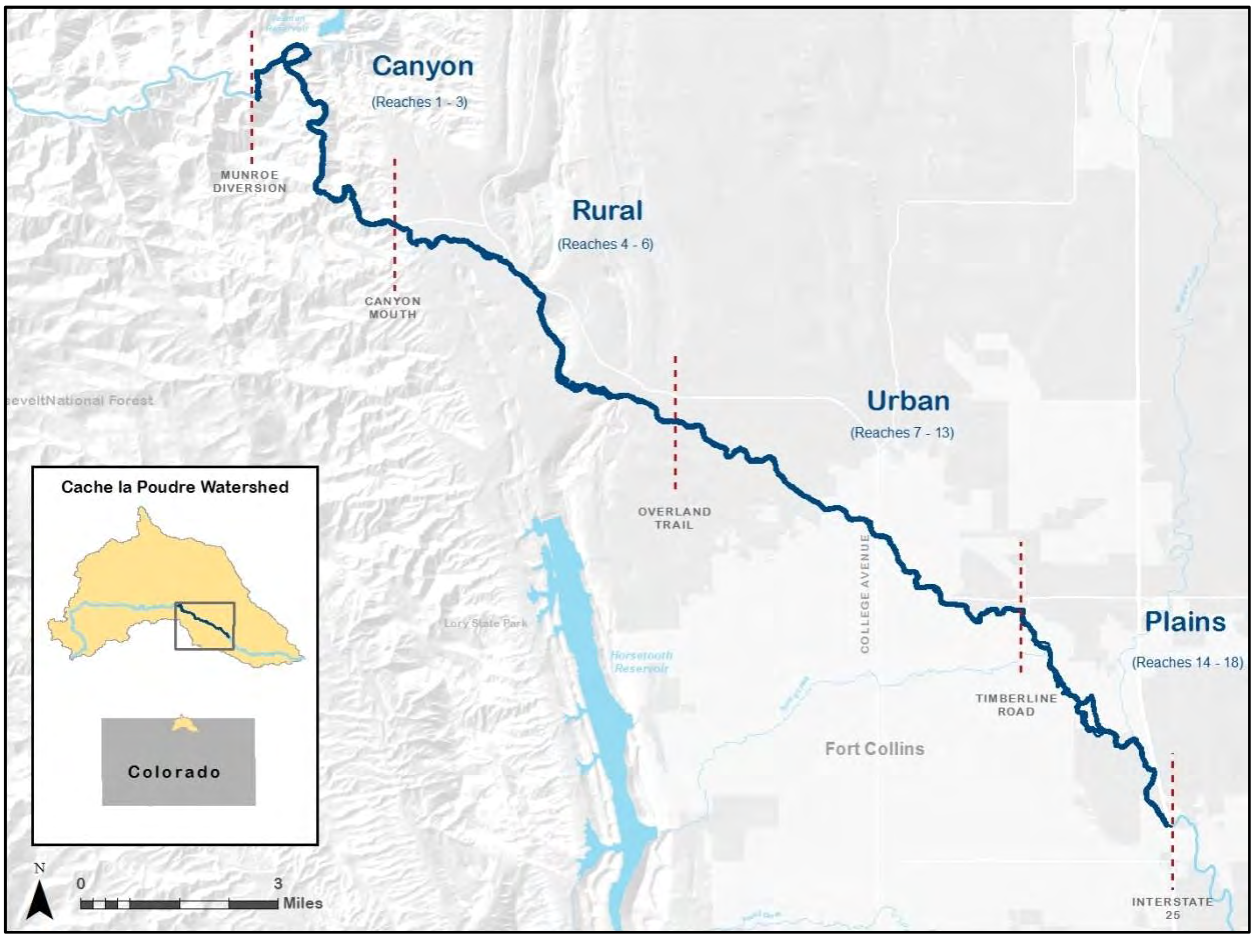

Figure 2.2: Map of the State of the Poudre River (SOPR) study area depicting the four study zones.

The four zones are divided into 18 reaches. Reach breaks mark important changes in river form, land use or water use (Figures 2.3 a-d). Because each sub-discipline in river science evaluates the condition of its resource at a subject-appropriate scale and using distinct approaches and data sets, all assessment results were translated to the 18 reaches during analysis and reporting. Appendix C provides further explanation of subject-specific sub-reaches and study site nomenclature established in other monitoring or research programs.

Table 2.3: A list of the landmarks used to define the upper and lower end of each of the 18 study reaches.

Location descriptions for each SOPR study reach
1. Munroe Canal Diversion to North Fork Poudre River
2. North Fork Poudre River to Poudre Valley Canal
3. Poudre Valley Canal to Greeley Diversion
4. Greeley Diversion to County Road 54
5. County Road 54 to Rist Canyon Road
6. Rist Canyon Road to just below Overland Trail*
7. Just below Overland Trail to Larimer Weld Canal
8. Larimer Weld Canal to Shields Street
9. Shields Street to College Avenue
10. College Avenue to Lincoln Street
11. Lincoln Street to Mulberry Street
12. Mulberry Street to Timnath Reservoir Inlet Canal
13. Timnath Reservoir Inlet Canal to Timberline Road
14. Timberline Road to Prospect Road
15. Prospect Road to Fossil Creek Reservoir Inlet Diversion
16. Fossil Creek Reservoir Inlet Diversion to Boxelder Creek
17. Boxelder Creek to Rail Road Bridge
18. Rail Road Bridge to Interstate-25

*The break point for this reach is at the downstream end of Butterfly Woods Natural area, which is located just downstream of Overland Trail.

Figure 2.3a and b: Each zone in the SOPR study area and their corresponding reach breaks shown on land imagery.

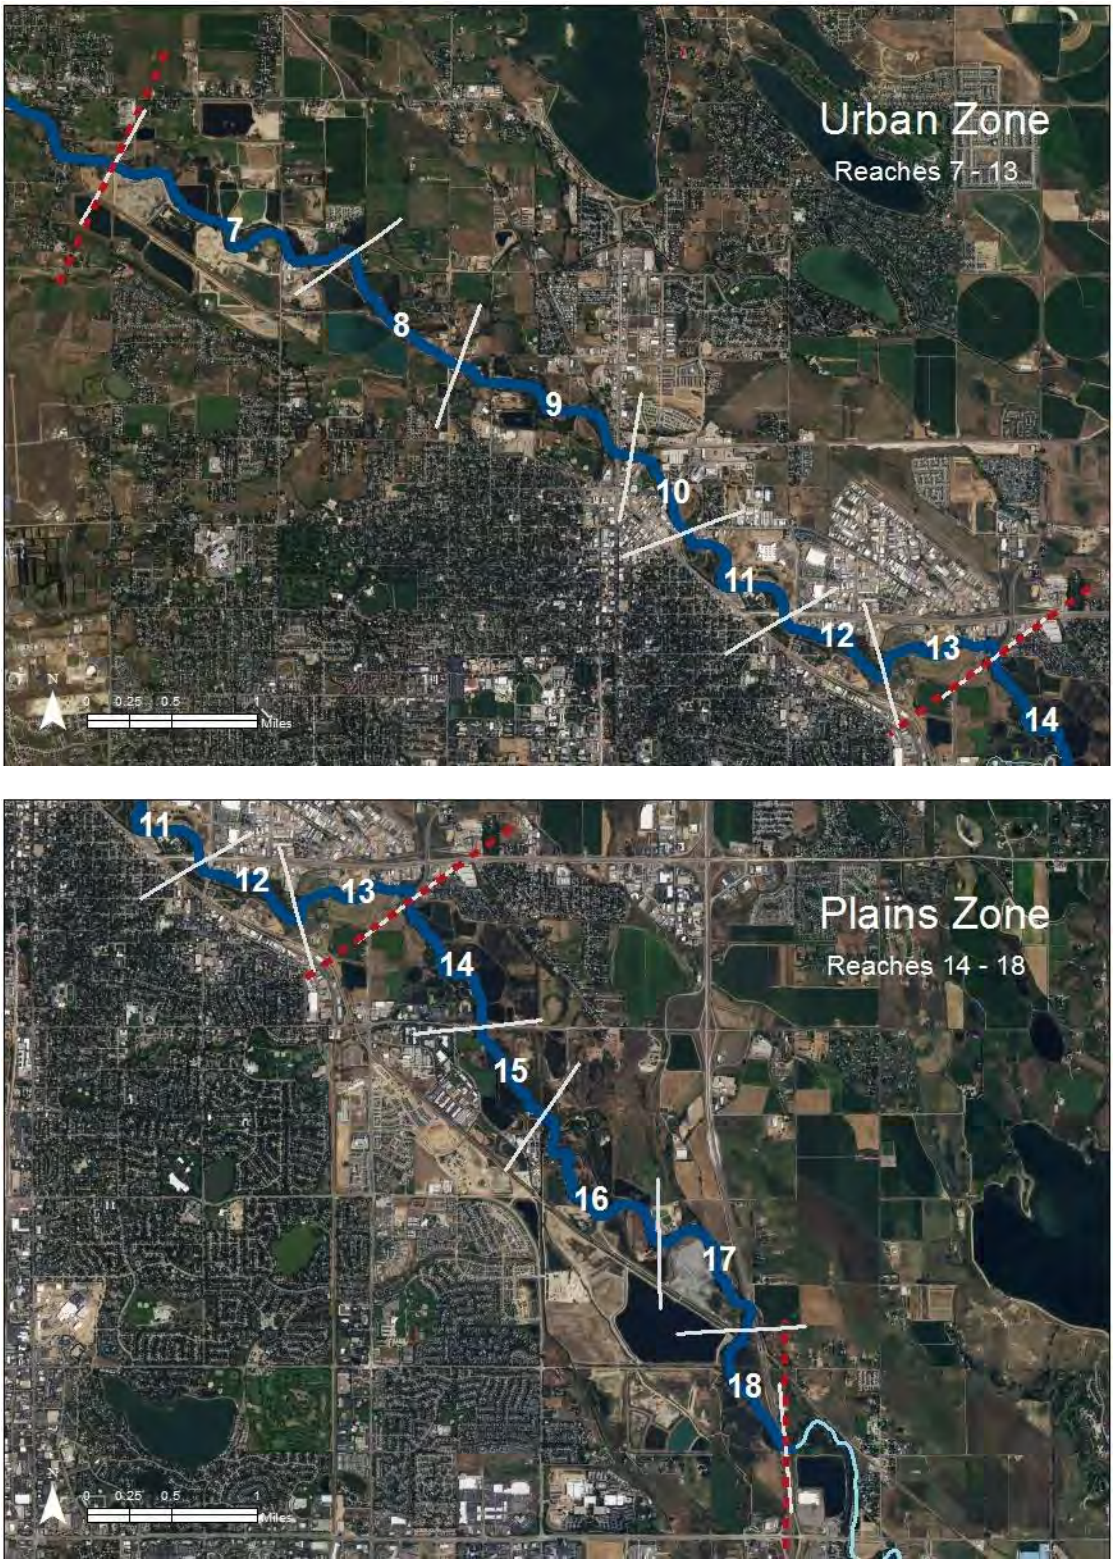

Figure 2.3c and d: Each zone in the SOPR study area and their corresponding reach breaks shown on land imagery.

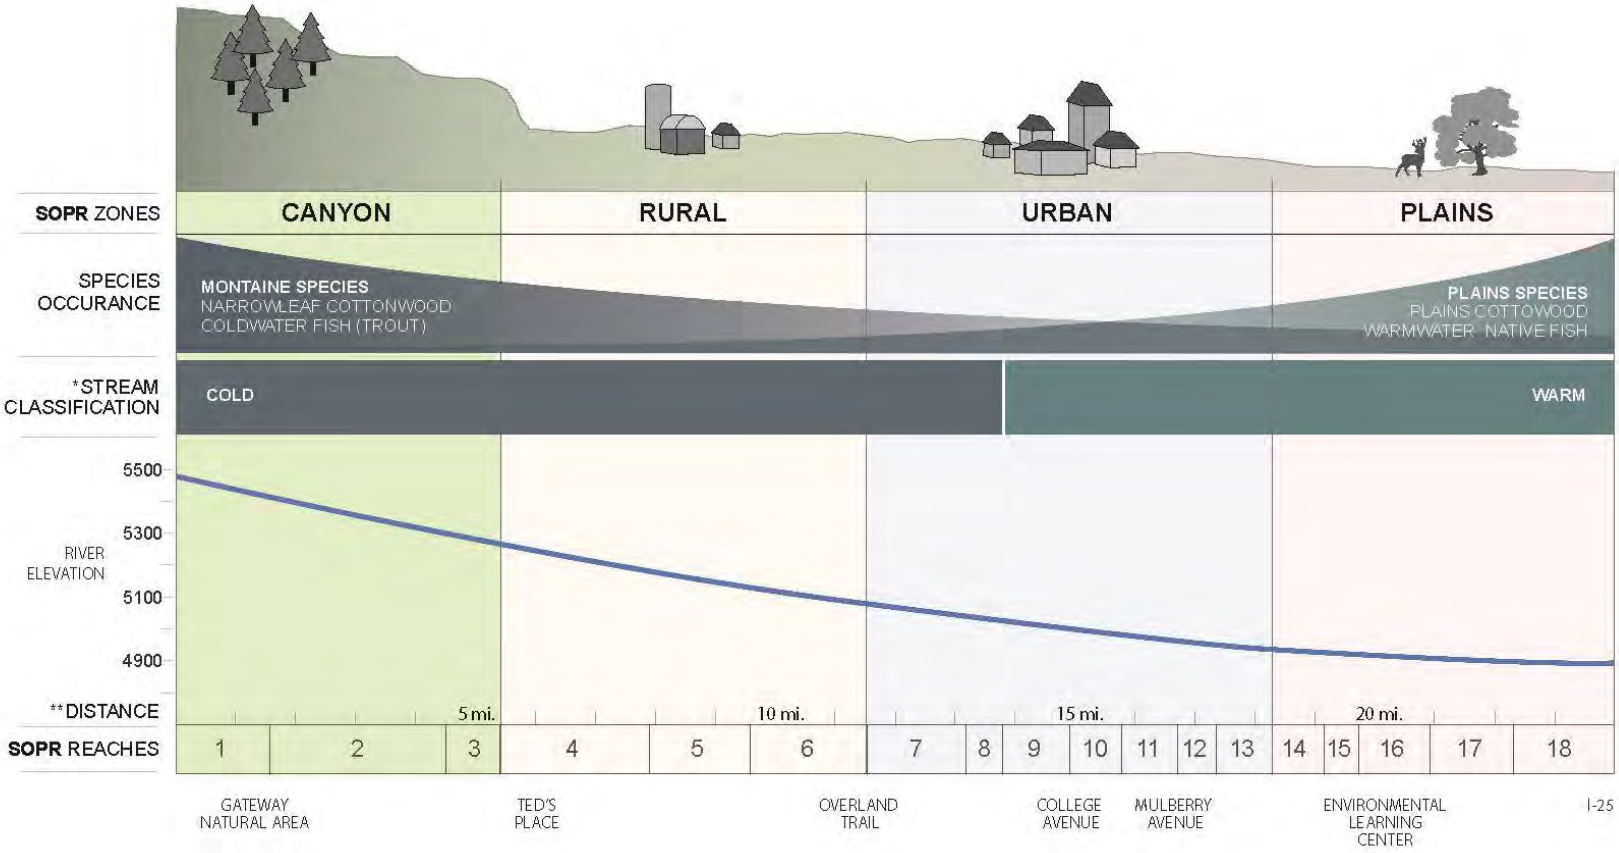
Figure 2.4: Conceptual diagram illustrating the transitioning nature of the river within the study area. Landmarks are presented at the bottom of this graphic. The specific zone and reach break points are listed in Figure 2.2, 2.3 and Table 2.3.



***Stream classification refers to the aquatic life use designated by the Colorado Department of Public Health and Environment. This transition zone includes three classifications (from upstream to downstream) aquatic life cold 1, aquatic life cold 2, and aquatic life warm 1. Temperature criteria for these classifications are cold stream tier II for both aquatic life cold classifications and warm stream tier II.**

**** The distance line in this graph shows the river miles within the study area, where zero miles is at the Munroe tunnel. The 24 miles SOPR study area sits approximately in the middle of the entire Cache la Poudre river which runs for a total of 126 miles.**

2.4 Scoring process

Throughout this report, metrics and indicators are presented as numeric scores or the corresponding letter grade for ease of interpretation. At the finest scale, metric scores were assigned to each assessment unit (a reach, sub-reach, or habitat patch) based on the specific scoring guidelines. Metric scores were then combined per the procedures described in Section 2.5 to produce indicators scores. Indicator scores were then combined into a river health grade for each reach and zone using a weighted average, and finally zone grades were combined to provide an overall health grade for the Poudre within the SOPR study area (Figure 2.5).

When combining indicators to develop zone based health grades, the framework takes into account the natural hierarchy in the influence that different indicators have on river health. That is, while there are many connections within and among the indicators, hydrological and physical indicators tend to influence biological indicators more than *vice versa* (a further explanation of this can be found in the RHAF). Therefore, the framework weights each indicator based on its relative influence on river heath, to provide a more accurate portrayal of river health.

The relative contribution of each indicator to the overall health score in the SOPR assessment is:

- Flow regime – 20%
- Sediment Regime – 5%
- Water Quality – 10%
- Floodplain Connectivity – 10%
- Riparian Condition – 20%
- River Form – 10%
- Resilience – 10%
- Physical Structure – 10%
- Aquatic Life – 5%

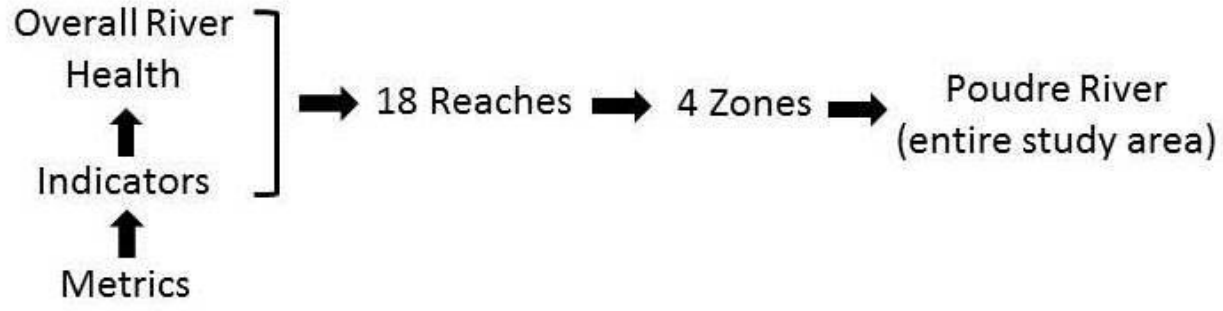


Figure 2.5 In this assessment, individual metrics are combined into indicator scores and then into holistic river health scores for the reaches, zones, and the entire Poudre River study area.

2.5 Field application of the River Health Assessment Framework

The specific methods used to grade each metric and indicator in this SOPR baseline assessment are described in this section. A combination of existing data, remote survey data, and field assessments was used to score each metric according to the revised Poudre RHAF guidelines. The complete and updated description of the grading guidelines for each metric is provided in Appendix B.

Flow regime

The flow regime indicator grade consists of three metrics: **peak flows, base flows,** and **rate of change**. These metrics were assessed using historical discharge data collected at three gages along the Poudre located at: the canyon mouth, Lincoln Street, and near the confluence with Boxelder Creek. Each gage represents a section of the river, and the SOPR employs the assumption peak flow conditions are uniform between gages. Reaches represented by each gage section were assigned a grade based on conditions measured at the gage. No attempt was made in this study to interpret impacts, such as diversions, at a finer scale within these three sections. Canyon zone reaches upstream of the gage at the canyon mouth were given the same grade as those below the canyon mouth, in the Rural zone.

As per the RHAF guidelines, a quantitative approach using sub-metrics for peak *three-day magnitude* and *frequency* was used in scoring peak flows. The grading guidelines were expanded upon from the RHAF in order to provide "+" and "-" modifiers for grades. This information is included in the grading guidelines for flows in Appendix A.

Trends in base flow magnitude, duration, and timing observed on plotted hydrographs for each gage were considered when scoring the **base flow** metric. To score the base flow metric, mean and minimum winter daily average discharge values were calculated for the period of record at each gage and compared to numerical standards. These calculations were then viewed in light of the other qualitative assessment scoring criteria to produce the final grade. The flow regime indicator grade was calculated using a weighted average of the three metric scores with 50% weight assigned to the peak flow metric and 25% apiece to the base flow and rate of change metrics.

Sediment regime

The sediment regime indicator has three metrics. The **land erosion** metric was graded using evidence for land disturbance that is visible on current aerial imagery, including: road density, devegetated slopes, clear-cuts, and human-caused mass erosion. The greatest land disturbance in the watershed is the burn scar left behind by recent wildfires. GIS layers outlining the burn scars by degree of intensity were used to calculate the percentage of burned area in the contributing watershed for each reach as part of the scoring for this metric. Land erosion metric scores in the Canyon and Rural zones are, therefore, closely tied to the proportion of burned area in the contributing watershed. In the Urban and Plains zones, sediment from other land uses and outfalls becomes more important. The combined influences of these sources were evaluated qualitatively during rapid field assessment.

A grade for **channel erosion** was applied to each of 99 river sub-reaches using evidence of channel erosion on current aerial imagery, and knowledge gained through field-based observations which

included on foot survey of most of the river in the project area in Fort Collins. Remotely assigned grades were re-evaluated during field surveys (see the river form, resilience, and physical structure sections, below). Sub-reach scores were weight-averaged by length to calculate grades for the respective reaches.

In-line dams affect sediment **continuity**, and the proportion of the contributing watershed from which sediment is retained was a primary basis for grading. Additional impacts to sediment continuity by smaller in-line diversion dams and transport limitations caused by flow regime and river form impairment were considered secondarily. Evidence of sediment-continuity impairment from these secondary sources was evaluated during field surveys.

The sediment regime indicator score was calculated as straight average of the three metrics.

Water quality

The water quality indicator grade was determined by evaluating data for four metrics **temperature**, **nutrients**, **pH**, and **dissolved oxygen** at several monitoring sites situated along the Poudre River (Appendix C). Data were collected in 2015 from seven monitoring sites associated with the Upper Cache la Poudre (CLP) Collaborative Water Quality Monitoring Program and the Lower CLP Water Quality Monitoring Program (Figure 2.6). Water quality data collected in 2015 were used here because the 2016 were not yet available at the time of the SOPR assessment.

Figure 2.6: At left, Jill Oropeza, Water Quality Services Manager analyzes water quality in the upper Poudre River. To the right, clear water, clean cobbles and low levels of undesirable algae are signs of good water quality.

The Poudre River was divided into eight reaches for the water quality assessment to evaluate impacts of potential stressor on water quality through the project extent. Reach breaks were established based on contributions from major tributaries and reservoirs, changes in Colorado Department of Public Health and Environment (CDPHE) Stream Segment and Classification, known dischargers to the Poudre River, and the location of water quality monitoring sites (Appendix E). Water quality data collected at monitoring sites located within a specified reach were used to grade the entire reach. In the one circumstance where a water quality monitoring site was not located within the reach (WQ3), data collected from the nearest downstream site (PLNC) were used to grade the upstream reach (WQ3). The

lowest elevation water quality reach (WQ8) was downstream of the end of the SOPR study area, but this reach was included in the grading assessment for water quality because the City's water treatment operations extend downstream of I-25.

Numeric grades for the eight water quality reaches were determined by evaluating metric data compared to updated RHAF grading guidelines for water quality (Appendix E). The overall water quality indicator grade was calculated using a formula that equally weights the average of the metric scores and the lowest of the metric scores [*water quality = 50% (average of metric grades) + 50% (minimum metric grade)*]. This method recognizes the cumulative effects of multiple water quality factors and also that one factor may serve as a limit to water quality. Water quality reach grades were then translated to the 18 SOPR reaches for consistency with other indicators and to be included in the calculation of the overall river health grade.

Floodplain connectivity

The floodplain connectivity indicator has only a single metric, **floodplain extent.** This is a measure of the width of the riparian zone that is flooded on a regular basis and which supports riparian species and processes (Figure 2.7). The extent of the five-year return interval floodplain was mapped using a Hydraulic Engineering Center – River Analysis System (HEC-RAS) model provided by the City of Fort Collins. Digital terrain data for the model came from a 2014 LiDAR survey and additional channel cross-section data from land surveys (King Surveyors, Spring 2013 and Spring 2014). The model covered the river reach from just upstream of Shields Street to just downstream of I-25. Channel widths were manually measured using aerial imagery at each modeled cross-section and then subtracted from the modeled water surface width to get the resulting floodplain width. For reaches upstream of where HEC-RAS model results were available, current aerial imagery was used to estimate the width of the 5-year floodplain. The degree of floodplain encroachment was estimated by evaluating evidence of land-use change and comparison to similar reaches for which modeled results are available.

Figure 2.7: A riparian area with good floodplain connectivity as demonstrated by the seasonal flooding that occurs and the healthy riparian forest sustained by floodwaters.

Riparian condition

The lateral extent of the SOPR riparian zone was defined as the edge of the natural floodplain or 100 meters from the river bank, whichever was narrower. In the SOPR riparian zone 3 metrics were assessed to develop riparian condition indicator grades. For the **vegetation structure** metric, the complex mosaic in the riparian zone was mapped by delineating patches (polygons) and classifying them by land cover using ten categories: native montane mesic, canopy forest, sub-canopy forest, scrub-shrub, herbaceous, emergent wetland, urban, developed, bare ground, or lentic open water. Patches were also classified by land use type, development level, and floodplain position using 2015 aerial imagery. City of Fort Collins Natural Areas mapping, National Wetland Inventory maps, and imagery from other years were also viewed to provide additional perspective. Mapped and classified patches were then evaluated to score the riparian condition metrics.

A two-level approach was used for evaluating the vegetation structure metric. The Level 1 approach was mainly a desktop exercise that relied on remote data such as aerial imagery and limited ground truthing. Field observations were incorporated at level 2. Assessment level was dictated by land cover and access. For instance, level 1 is sufficient for evaluating vegetation structure on urban, developed,

bare ground, and lentic (non-flowing) open water land cover types. Patches of simple herbaceous vegetation such as turf and lawns are also easily evaluated remotely, but field assessments are needed to suitably evaluate sites with more complex natural vegetation. As many complex vegetation patches as practicable were evaluated using level 2 methods, including 100 of the 218 canopy forest patches, 41 of 88 sub-canopy patches, 22 of 78 scrub-shrub patches, and 12 of 36 emergent wetland patches. The remaining patches in these classes were evaluated at level 1, using field evaluations to inform grading by comparing them with similar patches evaluated in the field.

Level 1 grading involved assigning grades based on evidence of vegetation structure visible in aerial imagery, and then downwardly adjusting the grade a little more than half a letter grade (7%) when patches were artificially isolated from the river (*e.g.*, when behind berms). For level 2 grading, nine sub-metrics were evaluated in the field:

- Vertical complexity – number of vegetation layers (herbaceous, shrub, sub-canopy, canopy)
- Canopy species – proportion of native species in the canopy layer
- Sub-canopy species – proportion of native species in the sub-canopy layer
- Shrub layer – abundance of shrubs
- Problem herbaceous species – abundance of non-native herbaceous species that alter function
- Problem woody species – abundance of non-native woody species that alter function
- Patchiness and interspersion – structural diversity by area, rated: none, low, moderate, high
- Native woody species regeneration – number of native, woody-species age classes
- Floodplain position – position on the floodplain, based on hydraulic connectivity to the river (riverine, depressional, or terrestrial)

Full description of the grading criteria for each of the riparian sub-metrics can be found in Appendix D.

Figure 2.8: Riparian forest with moderate structural diversity (left). Recently deposited plains cottonwood seeds on bare moist soil, shown in the photograph at right illustrate the ideal conditions for successful cottonwood germination.

The **habitat connectivity** metric was evaluated using aerial imagery to determine the amount of continuous riparian habitat remaining within the SOPR riparian corridor. Transverse breaks in habitat caused by development and infrastructure, such as roads, were then considered as possible migration and dispersal barriers. Where barriers are present, grades were lowered accordingly to reflect the degree of habitat isolation. The **contributing area** metric was also evaluated using aerial imagery to characterize land use in the 200-meter buffer area surrounding the delineated riparian zone.

The riparian condition indicator grade was calculated using a weighted average of the three metric scores with 80% weight on the vegetation metric and 10% each on the habitat connectivity and contributing area metrics.

River form

River form was rated using the average score of three metrics that describe key aspects of river shape: **planform, dimension,** and **profile**. All three of these metrics were graded at the sub-reach scale during field surveys by fluvial geomorphologists with experience on the Poudre and other Front Range rivers. 22.6 miles of the 23.9-mile study area was assessed in the field. The remaining 1.3 miles (on private land with no access) were scored using remote data such as aerial imagery. Scores reflect the degree of departure from natural reference river form for the respective reach using evidence of anthropogenic impacts, or stressors. Reach scores were then calculated as the average of the component sub-reach's scores, weighted by length.

Planform was assessed using aerial imagery and site observations for changes to river branching and braiding patterns, sinuosity, belt width, meander length and width, amplitude, and bend radius of curvature. Direct evidence of planform impairment was documented during field visits by noting areas of floodplain encroachment, channelization, realignment, and bank or channel armoring.

The **dimension** metric evaluates cross-sectional shape and size of the river channels, its associated floodplain, and flood-prone area. It is evaluated using three sub-metrics:

- *Entrenchment* – Degree to which the river channel is artificially confined or isolated from the floodplain. It is scored by evaluating criteria for the width of flood-prone area and the ratio of bank height to the height of water surface at bankfull discharge, or "bank height ratio". Entrenchment was not used to evaluate dimension in the Canyon zone since the river in that zone is naturally entrenched.
- *Width-depth ratio* - Degree to which the channel top width is has become wider or narrower relative to mean depth at bankfull discharge.

Profile describes a river's bed grade, or longitudinal slope. The metric is evaluated by documenting changes to overall slope, usually due to altered planform, and to localized changes caused by dams, grade control structures, or geomorphic responses such as aggradation zones or head-cuts.

Resilience

The resilience indicator grade is an average of two metrics: dynamic equilibrium and recovery potential. Both metrics were first remotely evaluated using historical aerial photos to document stability trends, changes to river form, lateral migration, avulsions, and erosion. Field observations were then made during site visits to observe stressors and direct signs of instability. For the **dynamic equilibrium** metric, stressors such as altered peak flow and sediment regimes, channel evolution stage, changes to stream form, and direct impacts such as channel and bank hardening were all taken into account. Signs of channel instability observable during field surveys included excess deposition, scour, or bank erosion, pool filling, unnatural bar development, and severely over-widened or entrenched channel form.

Recovery potential was graded considering the apparent potential for the reach to recover characteristic functioning after disturbance, while also considering risks to public safety and infrastructure damage. Two general criteria guided grading:

- *Channel migration zone* is the width of the corridor in which the river can freely migrate, unconstrained by artificial structures and without causing significant infrastructure damage. The width of the existing channel migration zone was compared to the historical condition, using evidence of past fluvial features and human impacts that restrict lateral movement of the river.

- *Reliance on artificial stabilization* measures was rated as the degree to which channel stability depends on artificial stabilization, such as engineered structures or routine maintenance.

Physical structure

The physical structure indicator grade is the average of two metrics that consider different scales of river structural diversity (Figure 2.9). The **coarse-scale** and **fine-scale** physical structure metrics were both graded based on field observations of the 22.6 river miles that were visited. Grades for the reaches on the 1.3 miles that were not observed in the field were extrapolated from similar reaches, guided by aerial imagery. Coarse-scale physical structure grades were based on qualitative estimation of the diversity of water depth/velocity combinations, topographic complexity of the bed and banks, and physical structure of the reach compared to the natural reference (Figure 2.9). Fine-scale structure grades relied heavily on field observations of interstitial space availability, bed armoring, embeddedness, and algae in riffles (Figure 2.10).

Figure 2.9a-d: Examples of different coarse-scale habitat conditions (clockwise from top left) include a) steeper plane-bed channel in the Canyon zone with large boulders providing diverse habitat, b) pool-riffle sequencing with large-wood helping create pool scour, c) homogenous run habitat lacking diverse coarse structure especially pool habitat, and d) homogenous glide habitat created from backwater conditions at the diversion dam downstream.

Figure 2.10: Field observations of interstitial space availability, bed armoring, embeddedness, and algae in riffles helped inform the fine-scale metric grades.

Aquatic life

The **aquatic insects** metric was evaluated using aquatic insects community data from samples taken from 13 sites in 2015 and 2016 (Appendix C). Results for six sub-metrics were used to calculate a single index score using the CDPHE Multi-Metric Index (MMI) tool, and the index values were converted to aquatic insect metric grades for each sampling site using RHAF guidelines. According to the MMI tool, a single index score (the MMI) was calculated for each sample as the average index from six sub-metrics. Aquatic insect metric grades were assigned based on the grading criteria in the Poudre RHAF. All reaches represented by a station were scored the same. The six sub-metrics used in calculating the MMI were selected based on their known sensitivity to a variety of types of human induced stressors in this region:

- EP taxa – a measure of community richness based on the number of Ephemeroptera and Plecoptera (mayfly and stonefly) taxa present
- Chironomidae – relative abundance of the family Chironomidae (non-biting midges)
- "Sensitive plains" families – percentage of certain sensitive taxa identified by CDPHE to be common on healthy Colorado plains' rivers
- Predator/Shredder taxa – relative abundance of taxa in the predator and shredder feeding groups
- Clinger taxa – relative abundance of taxa classified as clingers
- Non-insect taxa – relative abundance of non-insect taxa

The **aquatic habitat connectivity** metric was graded based on the distance between fish passage barriers, which are primarily diversion dams along the Poudre River. A structure is considered a barrier if it prevents fish from moving past (up) it for the majority of the year. All structures are passable in the downstream direction during the highest flows but currents under these flow conditions are too swift for upstream movement.

The length of the habitat connectivity segment between successive barriers was measured and scores were assigned. The aquatic habitat connectivity segment scores were overlaid on the 18-reach scale and then weight-averaged to determine final scores for each reach. The score for the most downstream reach is based on the distance to the Greeley Canal #2 diversion structure, which is the next significant barrier downstream, even though it is outside the study area.

Five stations were sampled in 2015 between College Avenue and I-25 by either CPW or the Colorado State University Larval Fish Laboratory (CSU-LFL) to assess **native fish** species composition (Appendix C). Seine nets and electrofishing methods were used at each station to capture live fish and determine the presence or absence of multiple life stages of native fish species (Figure 2.11). Metric grades were assigned based on two sub-metrics:

- *Number of native species* – Number of native fish species captured in sample efforts
- *Number of species with multiple life stages* – Number of species for which fish of multiple life stages were captured

Only reaches with 2015 sample stations were graded.

Figure 2.11: Colorado Parks and Wildlife staff electrofishing in a plains stream.

Trout are expected on the Poudre upstream from approximately the mid-point of the Urban zone. The **trout** metric was evaluated on these reaches by Colorado Parks and Wildlife (CPW) biologists who used two-pass electrofishing sample methods to monitor trout populations at several stations along the Poudre River annually. One station is at Gateway Park on Reach 1 (Munroe Diversion to North Fork) in the Canyon zone. Another is at Lee Martinez Park on Reach 9 (Shields to College) in the Urban zone. Results from these two stations, sampled in 2016, were used to grade the trout metric based on six sub-metrics:

- *Age classes* – Number of age classes of brown trout
- *Recruitment* – Number of Age-0 brown trout, assessed as low, medium, or high
- *Recreation potential* – Number of quality-size (> 9 inches) brown trout, assessed as low, medium, or high
- *Relative weight* – Average relative weight for stock-sized (> 6 inches) brown trout. Relative weight – the ratio of actual fish weight to the weight of a healthy fish of the same length – is a measure of fish health
- *Biomass*– Biomass of stock-size (> 6 inches) brown trout, in pounds per acre.
- *Population number* – Number of stock-size brown trout per mile of stream, assessed as low, medium, or high

The aquatic life indicator grade was calculated using a weighted average with 70% weight on the aquatic insects metric and 30% on the habitat connectivity metric. Trout and native fish scores are not included in scoring the indicator aquatic life since fish data for this assessment year was not available for the Rural zone and broad extrapolation of site specific data to the zone as a whole would have increased inconsistencies. Trout populations and native fish community structure mainly represent ecosystem response variables, rather than drivers of overall river health. Therefore, for this year's assessment fish grades are only provided where data was directly available.

3 Ecological stressors

The Poudre River, like all ecosystems, developed and evolved naturally in step with the geologic, climatic, and biological processes at play in the environment. The river's natural condition was one which defines ecological health – the river ecosystem was functioning in a dynamic equilibrium with climate and geology. The system was ever changing and often profoundly disrupted by shifts in the environment and extreme events. But the river's natural condition was resilient, and it would reshape itself based on the new constraints of the climate and landscape. Ecological health can be influenced—and functional capacity weakened—by human impacts. Stressors are the human impacts— past or present—that impair river health, resulting in decreased functioning if left unmanaged. Some forms of natural disturbance can be exacerbated by human activity and turned into stressors on the river ecosystem. One example is a wildfire that is either started because of human activity or exacerbated because of previous forest management that suppressed fires. The important ecological stressors affecting Poudre River health are described in this chapter (Table 3.1).

Table 3.1: Ecological stressors affecting Poudre River health.

	Stressors	Explanation
Watershed and contributing area	Diversions (withdrawals)	Exported water (withdrawals)
	Transbasin diversion (augmentation)	Imported out-of-basin water (augmentation)
	Large dams/reservoirs	Large in-line dams and reservoirs on the Poudre or major tributaries
	Wildfire/burn scars	Wildfire burn scars in watershed
	Channel erosion (in watershed)	Sediment supply from eroding channels (includes artificially low supply from stabilized channels)
	Impervious surfaces/urban stormwater runoff	Flows from impervious surfaces, urban drainage (including any pollutants)
	Irrigation runoff/return flows	Return flows (including any pollutants)
	Wastewater effluent	Effluent from treatment plants or facilities
River and riparian zone	Development	Riparian land use: commercial/industrial, infrastructure, transportation corridor, residential
	Rural/agricultural land use	Riparian land use: rural, pasture, light agriculture, intensive agriculture
	Open space and parks	Riparian land use: naturalized open space, parks, disturbed open land
	Gravel pit/ponds	Riparian land use: gravel pits, ponds
	Road/bridge	Roads and bridges in riparian and channel area
	Berms/channelization	Berms and channelized river segments
	Bank/channel armor	River segments stabilized with engineered structures, armored banks (*e.g*. rip-rap)
	Channel structures (dams/weirs)	Diversion structures, dams, weirs
	Woody material recruitment/removal	Lack of woody material recruitment (due to stabilization or riparian degradation) or removal
	Exotic plant species/weeds	Exotic plants in riparian area

3.1 Watershed and contributing area stressors

Stressors occur in the watershed or surroundings, and they are "inherited" by a river reach. Stressors in the watershed caused by land-use changes or other impacts primarily affect flow regime, sediment regime, water quality, and aquatic life, but river health may also be indirectly impaired in other reaches. For example, diversions in the headwaters that impair flow by truncating peak flows may also affect floodplain connectivity by reducing the return interval of overbank events far downstream. Similarly, the water quality of a reach may be impaired due to chemical impacts that occur far upstream. From the perspective of the City of Fort Collins, the critical difference between stressors occurring on properties under City management and those occurring elsewhere in the watershed is that the former may be addressable through changes in management practices, whereas the latter must largely be accepted as an inherited condition or improvements must be pursued by engaging in collaborative efforts.

Diversions *(flow withdrawals)*

There are numerous diversion points on the Poudre River upstream of I-25 where water is drawn out of the river for agricultural, industrial, and municipal uses. The major diversions were recently summarized for the City of Fort Collins Natural Areas Department (Figure 3.1) using records to quantify capacity and average annual volume. Fort Collins Utilities diverts roughly one-half of its water supplies from the Poudre River. Diversions occur at Gateway Park just upstream from the North Fork confluence. Other operations, such as exchanges and gravel pit operations, affect flows within the Urban and Plains Zones.

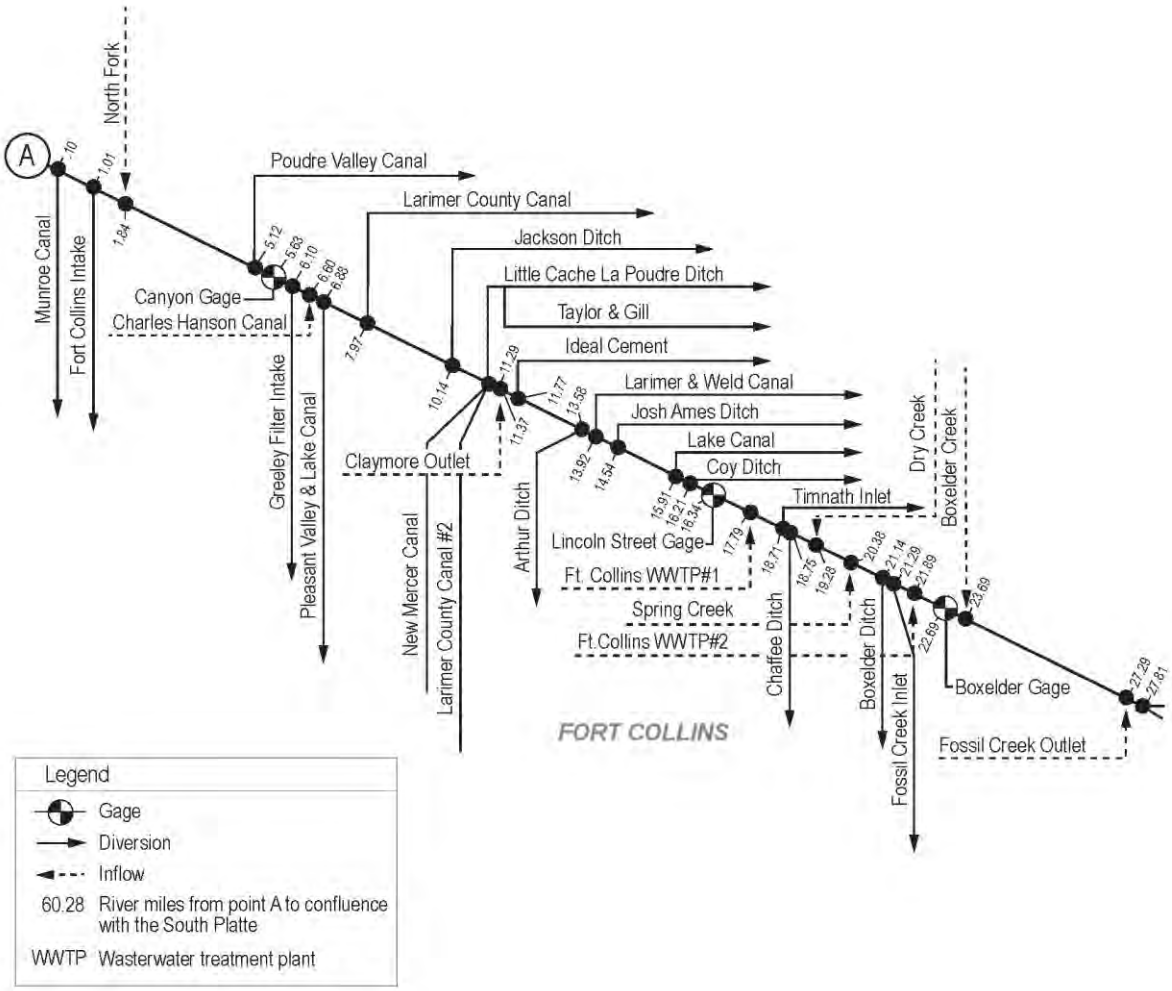

Figure 3.1: Line diagram of diversions and inputs on the Poudre, including the distance between each structure in the SOPR study area. This diagram illustrates how fragmented aquatic habitat is in the SOPR study area (provided by Northern Colorado Water Conservancy District, 1996).

Diversions directly affect components of flow regime, including peak flow, base flow, and rate of change. Peak flows can be truncated by diversions made during spring and summer, while base flows are commonly decreased by diversions during fall and winter or during drought. Rates of flow change can be impacted when diversions are opened and closed, especially during periods of low flow. The average rate and annual volume of water diverted during winter months (November through March) were also calculated for each diversion point. An average of about 38,000 acre-feet per year is diverted from the Poudre in or above the study area during winter months, and wintertime dry-ups sometimes leave the river with little to no flow (Table 3.2).

Flow withdrawals can also affect water quality and physical structure. Excessively low flows elevate radiant heating and cooling, making the river vulnerable to extreme temperatures with increased highs in summer, decreased lows in winter, and greater diurnal fluctuation. Low flows may also exacerbate chemically-related water quality issues such as nutrient loading and suppressed dissolved oxygen content by lessening the effectiveness of dilution, altering biogeochemical processes, and limiting the effectiveness of turbulence and mixing. The amount, availability, and diversity of physical structure (*i.e.*, riverbed habitat available to fish), may be severely limited during low flow periods, which can directly affect aquatic species survival especially during critical late summer, fall, and winter flow periods. Low flows are more of a stressor in some reaches during late summer and fall and some reaches are particularly affected by wintertime diversions (Table 3.3).

Table 3.2: Annual average volume, wintertime average volume, and wintertime average discharge values for the indicated period of record (Bishop-Brogdan Associates, 2015).

Poudre River Wintertime Diversion summary				
Diversion	Wintertime average diversion (Nov-Mar)			
	AF	CFS	Frequency	Period
Worster/Eaton Reservoir	420	1.4	fairly constant	1997-2013
Halligan Reservoir	3,900	13.0	fairly constant	1997-2013
North Poudre Canal	3,500	13.0	each year since 2002	1997-2013
Milton Seaman Reservoir	570	1.9	sparse (since 2001)	1997-2013
Long Draw Reservoir	690	2.3	fairly constant	1997-2013
Peterson Lake Reservoir	N/A	N/A	sparse	1997-2013
Joe Wright Reservoir	540	1.8	fairly constant	1997-2013
Chambers Lake Reservoir	1,650	5.5	fairly constant	1997-2013
Barnes Meadows Reservoir	30	0.1	sparse	1997-2013
Munroe Canal	210	0.7	some since 2009	1997-2013
Fort Collins Pipeline	1,900	13.0	fairly constant	1997-2013
Poudre Valley Canal	270	0.9	sparse	1997-2013
Greeley Filters Pipeline	6,225	20.8	almost always	1997-2012
Watson Lake Diversion	25	0.1	constant	1997-2012
Little Cache Diversion	1,150	3.8	fairly constant	1997-2012
Larimer and Weld Canal	3,330	11.0	fairly constant	1997-2012
Timnath Reservoir Inlet	5,010	16.7	constant	1997-2012
Fossil Creek Reservoir Inlet	6,190	20.6	constant	1997-2012
Total	**37,980**	**126.6**		

Table 3.3: Base flow statistics for points just downstream from five of the diversion points on the Poudre for the period 1970 to 2010. (Bishop-Brogdan Associates, 2015).

Base Flow Criterion	Greeley Filters Pipeline Diversion	Little Cache Diversion	Larimer Weld Canal Diversion	Timnath Reservoir Inlet Diversion	Fossil Creek Reservoir Inlet Diversion
Average number of days per year with continuous flow below 35 CFS	102	104	135	136	178
Average percent of winter days with flow below 35 CFS	77%	74%	75%	74%	79%
Average number of days per year with continuous flow below 10 CFS	28	31	75	70	111
Average percent of winter days with flow below 10 CFS	38%	27%	51%	52%	65%
Average number of days per year with continuous no flow	3	9	12	16	24
Average percent of winter days with no flow	6%	6%	19%	17%	23%

Transbasin diversion *(flow augmentation)*

At the higher elevations of the Upper Poudre Watershed, transbasin diversions import water to the Poudre River from other drainages through the Wilson Supply Ditch, Laramie-Poudre Tunnel, Grand River Ditch, and Michigan Ditch. Colorado-Big Thompson water is delivered to the Poudre through the Hansen Supply Canal via Horsetooth Reservoir. Flow augmentation via transbasin releases can have opposite effects of diversions. Releases timed with natural runoff or storm flow peaks can increase peak flow magnitude or duration, and releases during winter or other periods of low flow can supplement naturally low discharge, thereby offsetting some of the impact of diversions. Transbasin diversion releases introduce another mechanism by which flow rates can be artificially and rapidly changed and they can also impact river water quality depending on how water quality differs between the Poudre and the imported water.

Large dams/reservoirs

There are multiple reservoirs within the Upper Poudre Watershed and two large dams on the North Fork that impact the flow and sediment regime along the Poudre River. Halligan and Seaman Reservoirs are both created by large in-channel dams that regulate flow regime and cut off sediment supply to the Poudre mainstem downstream. The effects on base flow vary depending when calls on water rights are made by downstream users. However, reservoir management has the potential for exacerbating low-flow impairment and altering the rate of flow change. Reservoirs also effectively trap the vast majority of the natural and anthropogenic supply of bedload and suspended sediment, delivering mostly sediment-free discharge downstream which can exacerbate channel and bank erosion.

Other potential impacts from large dams and reservoirs include changes in water quality. Because reservoirs expose large surface areas to the sun, deep reservoirs can become thermally stratified during the summer months, resulting in warmer surface waters and colder bottom temperatures. Depending on whether reservoir water is released via a surface spillway or a bottom outlet, stream temperatures may be warmed or cooled accordingly. In this way, dams can impact the natural temperature regime of downstream receiving waters. Seasonal thermal stratification in reservoirs can also result in oxygen depletion of the bottom waters. Under these low oxygen conditions, biological processes mobilize nutrients and metals bound to bottom sediments, which can result in seasonal spikes in dissolved nutrient and metals concentrations in waters released from reservoirs. Dams are also a clear example of an extreme barrier to passage of fish and other aquatic organisms.

Wildfire *(burn scars)*

Recent wildfires in the Poudre watershed left burn scars with decreased forest cover and exposed soils that are more susceptible to runoff and erosion and deposited large amounts of ash and fine sediment into the river (Figure 3.2, 3.3). Until the vegetation sufficiently recovers, the burn scars will have a significant impact on sediment regime (land erosion) and flow regime (peak flows and rate of change). Wildfire is a natural part of the geological and ecological setting within which the Poudre River evolved. Nevertheless, decades of fire suppression in the watershed have altered the frequency, magnitude, and distribution of fires, thereby increasing tributaries.

Figure 3.2: Post fire erosion creating turbid waters.

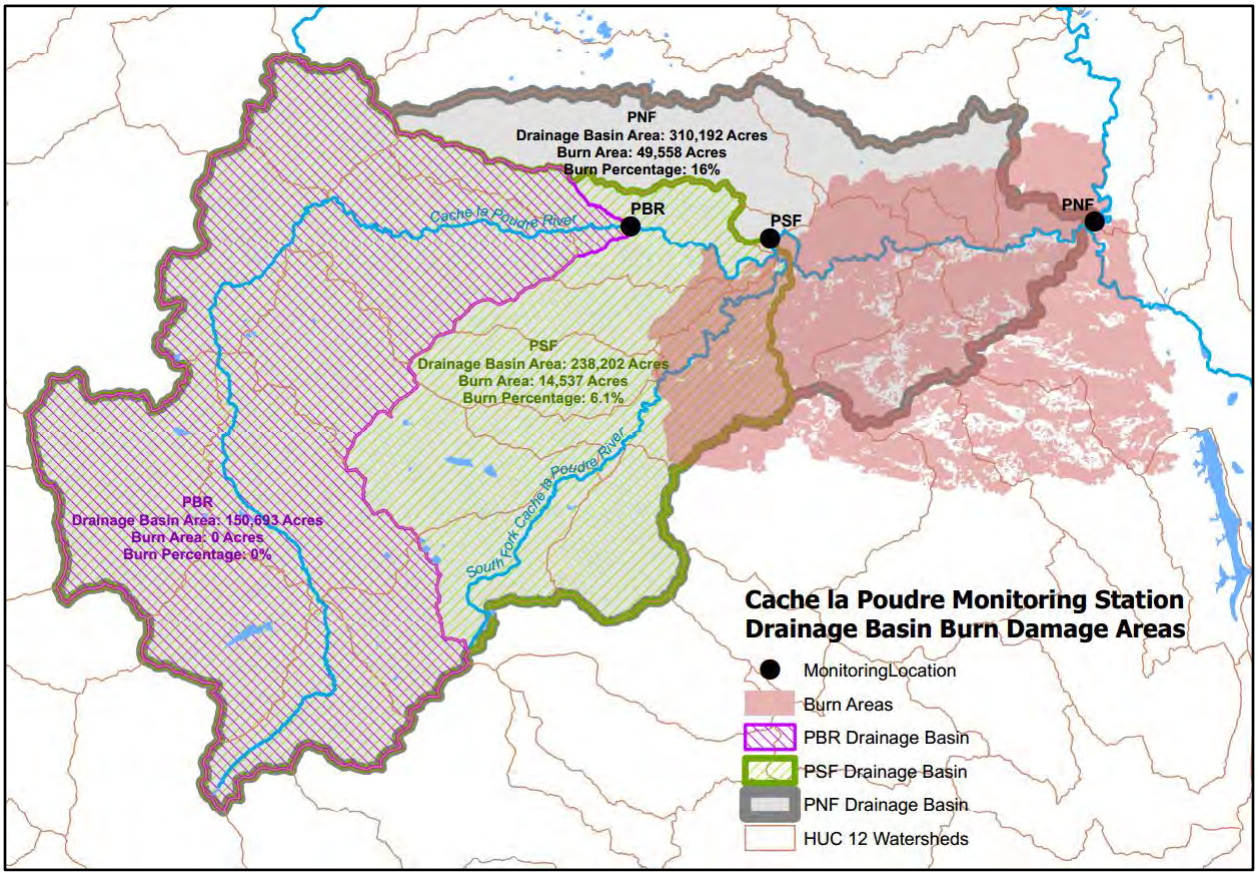

Figure 3.3: Percentage of burned area for watersheds at different points on the river (From Hohner et. al., 2016)

Channel erosion

The river is in a state of equilibrium when the sediment supply and transport capacity are in balance. Changes to land use, hydrology, or the river itself can shift this balance causing the channel to incise, aggrade, or widen as it adjusts towards a new dynamic equilibrium. Channel erosion is a natural process that allows the river to achieve this new dynamic equilibrium, resulting in the release of sediment. However, channel erosion is not always acceptable in a given location, and artificial measures such as riprap and grade control structures used to stop channel erosion are common on the Poudre and its tributaries. Artificially-stabilized river and stream sections deliver less sediment downstream, except during extreme events.

Irrigation runoff and return flows

Return flows and runoff from irrigated lands recharge flows in the river and often introduce non-point-source pollutants—particularly nutrients—which come from decaying organic material and fertilizer. Return flows offset depletions since they represent the return of diverted water back to the river, but less water is returned than was diverted because of consumptive losses, and that water is returned to a point downstream of the diversion, leaving the upstream reach dewatered.

Treated wastewater effluent

Treated wastewater effluent enters the Poudre River in three locations within the study area. Additionally, the outflow from Fossil Creek Reservoir discharges a mix of river water, wastewater from two water treatment facilities, and localized stormwater runoff into the Poudre just downstream of the study area (this site is discussed in Section 4). Treated wastewater effluent discharges are permitted by the State of Colorado and must meet quality standards designed to protect designated uses, such as aquatic life. However, despite the use of advanced technologies for nutrient removal and regulated quality standards, wastewater effluent water is typically warmer and higher in nutrient concentrations than the ambient river water, and as such, represents a potential stressor on river health. Its impact, however, depends on the time of year, streamflow, and the proportional volume of effluent in the river.

Because nutrients and temperature typically exert strong influences over productivity in local streams, excessive nutrient and thermal loads have the potential to increase algae growth and drive changes in community composition of both algae and aquatic macroinvertebrates, as well as dissolved oxygen content. Furthermore, native fish have specific temperature tolerance ranges, beyond which their ability to survive and reproduce may be impacted.

3.2 River and riparian zone stressors

Development

All commercial, industrial, infrastructure, transportation, and residential land uses in the riparian zone may be considered stressors (Figure 3.4). Commercial/industrial land uses are mainly retail and manufacturing facilities that introduce a substantial amount of artificial roof, impervious surface, bare ground, or open water cover types to the riparian zone. Infrastructure areas contain the structures, systems, or facilities that serve the public interest. Roads and railways were mapped as transportation corridors, and paved paths were considered part of the transportation corridor when they were associated with a road. Residential development is typified by suburban moderate-density housing. Residences in the riparian zone are relatively few, with most being single-family units with manicured/landscaped lots or lawns. Some high-density housing units are present in the Urban zone. These land uses are considered direct impacts to the riparian condition, affecting vegetation structure, habitat connectivity, and contributing area. They also severely limit active floodplain function since they need to be protected via channelization, berms, and fill.

Figure 3.4: Development in the historical riparian area is a stressor on reaches in the Urban and Plains zones.

Rural and agricultural land use

Ten percent of the riparian zone was mapped as "rural or agricultural" (Figure 3.5). Rural development areas are still largely vegetated, but vegetation cover is often dominated by disturbance-loving or exotic species. These lands include occasional buildings, structures, and unpaved roadways with pastureland,

and light to intensive agriculture. Most pastureland was developed by clearing woody riparian vegetation from the riparian area then managing it as grassland. Light agriculture includes hay fields and open land used for livestock grazing. Row crops, penned livestock, or confined animal feeding operations are in the intensive agriculture category. These riparian and floodplain land uses vary greatly in their effect on river health. Light agriculture and pasture is generally compatible with flooding and they provide some basic floodplain functions where they have not been drained or physically cut off by berms.

Figure 3.5: Rural development covers ten percent of the mapped riparian zone.

Open space and parks

Sixty-four percent of the riparian zone remains open space (under various forms of management) and park land (Figure 3.6). These lands include properties holding remnants of preserved native habitat, or areas that were settled and altered in the past that have since been managed with the express goal of maintaining or enhancing native species and natural system function. Even with current management by open space programs, these lands continue to exhibit a wide degree of impacts remnant from previous land uses. The most disturbed open areas—such as vacant lots, abandoned roads, and naturalized roads and berms—tend to have less vegetation and are often dominated by weedy or exotic species. On the other end of the spectrum, some properties have been restored specifically to support river function by improving river-floodplain connectivity and creating the ideal physical conditions for the native flora and fauna to flourish.

These lands are also managed to provide recreation opportunities and so include infrastructure such as paved multi-use trail, bathrooms, and pavilions all of which influences natural system function. Parks dominated by turf, recreational infrastructure, parking lots and sidewalks also fall into this stressor category. Parks impair function to a much greater degree than the naturalized open spaces, because of their lack of structural diversity and contribution of nutrients and other chemicals to the river.

Figure 3.6 While open space and parks management of lands in the floodplain primarily has a positive influence of river health, infrastructure such as the bike bath in this photo is often located so close to the river that it's protection disconnects the river from a functional riparian zone .

Gravel pits and ponds

Gravel pits and ponds account for eight percent of the SOPR riparian zone land cover (Figure 3.7). Gravel mining has been a prominent industry along the Poudre floodplain corridor almost since the town was first settled. In the City of Fort Collins natural areas alone, there are more than 30 former gravel pits and ponds. Most of these are excavations filled with alluvial groundwater that are separated from the river by berms or dams. Gravel ponds represent a conversion of vegetated riparian habitat into open water, and therefore they are a direct and severe impact on riparian condition. In some cases—where they are not fully surrounded by berms and gravel pits—ponds still offer some floodplain function by providing area for overbank flows to spread, but ponds provide no floodplain roughness. Bermed gravel pits and ponds contribute to instability and poor resilience by introducing the risk of catastrophic failure and avulsion (*i.e.*, rapid abandonment of a river channel and the formation of a new one). Recovery from massive avulsions is slow and unpredictable, and it can be quite expensive if the issue must be actively addressed. The numerous examples where Front Range rivers cut new channels through gravel pits and ponds during the 2013 flood provide direct evidence of these potential risks and the consequences. Gravel pits and ponds also affect groundwater dynamics, habitat connectivity, and (potentially) water quality.

Figure 3.7: Gravel pits and ponds are a common floodplain land use in the Urban and Plains zones.

Roads and bridges

Roads and bridges affect river health in several direct and indirect ways. Highway 14 parallels the river through the Canyon zone (Figure 3.8). The valley bottom is so confined and narrow in this zone that road encroaches on the riparian zone, the floodplain, and even on the channel itself where it affects floodplain connectivity, riparian condition, river form, and resilience. Below the canyon, roads also contribute to floodplain encroachment, especially where perpendicular cross-fills consolidate flows through bridges openings. Two bridges span the Poudre in the Canyon zone, four on the Rural zone, twelve in the Urban zone, and four in the Plains zone (Figure 3.9). Bridge effects vary by design and span length, but they generally limit floodplain extent, impact riparian condition, and reduce resilience. In most cases river form and physical structure are also directly affected.

Figure 3.8: Highway 14 road fill encroachment in the riparian floodplain is common in the Canyon zone.

Figure 3.9: Twenty-two bridges span the Poudre in the study area. At left, a railroad trestle and College Avenue and at right Prospect Road.

Berms and channelization

Downstream of the Canyon Zone, a majority of the river is channelized and/or bounded by berms (Figure 3.10). These practices are important for protecting floodplain development and infrastructure, but they also have a significant impact on river ecology and health. In addition to limiting floodplain extent, which is their intended purpose, channelization and berms directly impact riparian condition and all the geomorphic indicators of river form, resilience, and physical structure. Channelized reaches have decreased sinuosity and length, limited branching or braiding, narrow and often entrenched channel dimension, increased slope, and typically homogenous bed and bank structure. Resilience is compromised by the reliance on engineered structures to maintain river form and to protect human life and property. When berms breach or when channelized reaches avulse, as they occasionally do, there is little potential for passive recovery.

Figure 3.10: Channelization and berms are common on the Poudre River as shown in the two photographs here.

Bank and channel armor

Armor—such as engineered streambanks, riprap, and concrete— is used to strengthen the riverbed and banks to maintain channel resistance and to prevent its migration or movement (Figure 3.11). These treatments work by increasing channel hardness or resistance to scour, usually with the intent of protecting development, infrastructure, and property from channel migration or erosion. Combined with channelization and berms, bank and channel armor limits the width of the channel migration zone, which is the area within which the river can safely and effectively migrate. By arresting the natural processes by which the river moves, adjusts, and maintains habitat diversity, channel and bank armor directly impacts river form, resilience and physical structure. Revetments provide resistance to these processes so that the river maintains its form despite changes that may be occurring in the channel dimension and profile upstream. The physical structure indicator is impaired by armoring since armored banks prevent the increased channel sinuosity and lateral scour that would normally maintain lateral scour pools and bank undercuts.

Figure 3.11: Bank and channel armoring is employed to increase channel resistance, protect above and below ground infrastructure or prevent river migration.

Channel structures *(such as dams, weirs)*

There are 19 dams and several other weirs and grade control structures on the Poudre in the study area. Four of the dams are in the Canyon, five in the Rural, six in the Urban, and four in the Plains zone (Figure 3.12). Dams, weirs, and grade control structures are additional channel armoring features that resist erosion and lock the channel in place. Most of the dams serve as control structures for the major water diversions, while other structures provide grade control and channel stability functions. Regardless of their intended function, most of these structures have severe local impact on river form, resilience, and physical structure. Like armoring, rigid structures prevent channel movement and adjustment, and they impose an artificial channelized dimension and planform. With heights that reach eight or more feet, diversion dams are a major impact to river profile, creating long flat slackwater sections upstream where deposition leads to homogenous plane-bed structure at the coarse scale, while at the fine scale substrate becomes embedded or armored. Most of the structures are engineered to resist scour and failure due to erosion even in extreme floods, but when they do fail there is little to no recovery potential, and expensive emergency repairs are often necessary.

Figure 3.12: There are nineteen major structures or dams on the study area. Some pose major barriers for fish (left), while others are much lower and may be passable at some times of the year (right).

Woody material recruitment and removal

Woody material was historically a very important driver of river form and function on the Poudre, but in-stream wood has become scarce in its modern-day stabilized and channelized form (Figure 3.13). Riparian development and deforestation led to a decreased supply of wood, but berms, channelization, and armoring are also important factors that limit accumulation of woody material. Unconfined rivers normally accumulate wood as they migrate through forested riparian zones, entraining trees via active bank erosion or when dead wood on the floodplain is rafted in during floods. Both of these mechanisms are now severely limited in the study area. Moreover, when large woody material does become entrained in the river, it is often physically removed as part of maintenance programs. In a natural state, large woody material and log jams in the river create overhead cover, hydraulic diversity, and structural diversity by impounding water and/or inducing localized scour that forms pools. Even today, some of the deepest pools and most complex habitat are in locations where wood has been allowed to collect and become integrated into the channel.

Figure 3.13: Large woody material in the river creates important structural complexity and habitat diversity for fish and other aquatic life (left). Beavers play an important role in the cycling of large wood in river systems (right).

Exotic vegetation

The list of exotic vegetation in the riparian corridor includes a suite of species from regulated noxious species to species that are less noxious but extremely aggressive and prolific in nature. Noxious species are not a great concern in most of the study area because there has been proactive management in City of Fort Collins Natural Areas to eradicate them over the past decade. Properties managed by other entities may have greater problems with noxious weeds, and those properties can act as a nuisance seed source to surrounding managed lands.

Non-native species impair ecosystem functions where they dominate habitat niches formerly occupied by native species. Three species that are known to heavily impact Poudre River riparian forest function are: crack willow, reed canary grass, and smooth brome. While these are non-native, none are regulated as noxious species, yet all are extremely successful at establishing and spreading, and eventually dominating habitats. As they take over, these exotic species are resistant to scour and infiltration by other species, leading to a static vegetative community that hinders the natural processes of forest renewal by decreasing the number of sunny bare sites needed for native woody species regeneration.

4 Assessment results for the indicators and metrics

4.1 Overview of river health grades

Compiled *indicator scores* produced **river health grades of B- to C- for the 18 reaches of the Poudre River** (Table 4.1). The overall grade for the Canyon zone was a B-, while the Rural, Urban, and Plains zones were all in the mid-C range. The causes of impairment to the Poudre vary by reach and zone (see Chapter 3). This chapter describes the effects of those stressors on each indicator and metric of river health.

Table 4.1: Summary of river health indicator scores and letter grades organized by zones and reaches. Numerical scores are provided to illustrate the often subtle differences in the condition of health indicators. The assessment framework for the Poudre River uses a straight academic grading scale, where 90 and greater is an A grade, 80 and greater a B grade and so on. Letter grades are indicated through color coding. A key is presented below the table.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Flow Regime	77	75	75	74	74	73	73	72	72	72	69	69	69	69	69	70	77	77
Sediment Regime	91	84	84	83	82	81	83	82	81	79	79	80	79	79	79	79	79	79
Water Quality	88	77	77	77	87	87	87	87	89	89	89	89	88	88	88	86	83	83
Floodplain Connectivity	78	82	85	74	65	85	62	61	87	50	67	73	70	77	50	98	82	71
Riparian Condition	85	87	85	77	73	74	64	69	76	63	65	70	71	73	70	76	71	68
River Form	82	74	72	79	68	78	67	74	76	70	78	74	75	77	67	74	75	69
Resilience	82	79	76	79	75	76	67	77	78	69	79	77	74	75	71	76	74	68
Physical Structure	76	74	71	82	72	79	66	77	79	77	81	70	77	76	63	74	74	69

	80			76			74							75				

Grading Scale		
	A	100-90
	B+	89-87
	B	86-83
	B-	82-80
	C+	79-77
	C	76-73
	C-	72-70
	D/F	69 or low er

Before diving further into the metric level results it is helpful and important to acknowledge uncertainty and variability within this vast project. The SOPR assessment team recognizes there are various levels of uncertainty in the results across reaches because of distinctions between scientific disciplines, river reaches and local context, data sources, data years available and combinations of qualitative and quantitative assessment approaches.

4.2 River health grades by indicator

Flow regime

The flow regime indicator grades range from C to C- suggesting substantially-impaired functionality throughout the study area (Table 4.2). Impairment mainly arises from the effects of water management. Most of the fundamental physical and life-support functions are still sustained, but higher-level functioning requires active management to accommodate or mitigate the altered flow regime.

When considering the results for all three flow metrics, note that there are various degrees of uncertainty in the results across the zones corresponding to data availability or lack thereof. Most notably, the Canyon zone was evaluated using the general qualitative grading guideline descriptions and a general high level evaluation of changes to flows, in contrast to the lower three zones that were assessed quantitatively. Furthermore, the quantitative assessment for the lower three zones was conducted using gage data and grading guideline "thresholds" that originate from specific locations on the river. Therefore the further one moves from these locations, the greater the uncertainty.

Table 4.2: Summary of flow regime indicator scores and grades organized by zones and reaches.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Peak Flow	81	78	78	78	78	78	78	78	78	78	72	72	72	72	72	75	88	88
Base Flow	72	72	72	68	68	65	65	62	62	62	62	62	62	62	62	58	58	58
Rate of Change	73	73	71	70	70	70	70	70	70	70	70	70	70	70	70	71	75	75
Flow Regime	77	75	75	74	74	73	73	72	72	72	69	69	69	69	69	70	77	77
	76			73			71							73				

Peak flows

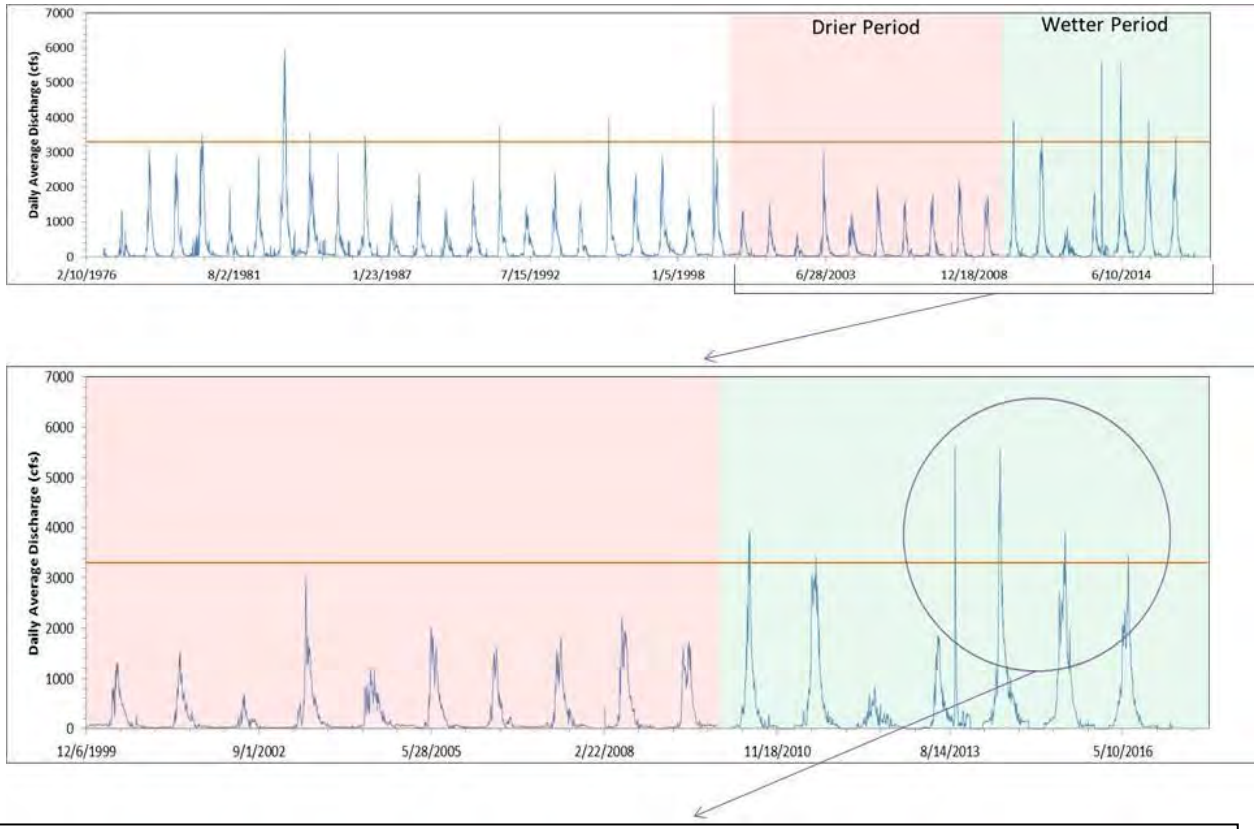
The reduction of peak flows results in an adverse effect on the river's ability to carry out vital functions. The C+ to C- zone level grades for this metric indicate that flows sufficient to mobilize and flush bed material do occur, but less frequently and with less certainty than needed to help support a functionally healthy and resilient river. From the upper reaches of the study area a C+ grade is reported for each reach until halfway through the Urban zone where at reach 10 the cumulative impact of multiple diversions drives the score down to a C-. In the lowest two reaches in the Plains zone, peak flow metric grades jump from C- to B+. This grade improvement represents an increased ability for the peak flows to move sediment, rather than larger or more characteristic peak flows. The improvement in functioning is due to the smaller sediment size found here, which require lower flow magnitudes to accomplish the same bed-mobilization functions. In other words the magnitude and frequency of peak flows downstream from the Boxelder gage is sufficient to support natural channel maintenance functions, such as scour and bed flushing, at a higher functioning level (B+).

The grading guidelines for the peak flows metric are based on the thresholds for river bed mobilization modeled in the ERM. Bed mobilization is critical for maintaining habitat and the life cycle needs of aquatic insects and fish that rely on clean interstitial spaces between coarse bed materials. Another important role of bed mobilization is to prevent armoring, or conversely, sedimentation. These

processes can have a cascading effect on a spectrum of other important functions associated with a healthy river. The peak flow thresholds needed to perform other functions such as algae scour, channel maintenance and certain riparian processes may correlate to (but are unlikely to be the same as) the bed mobilization thresholds. But these other important functions were not explicitly analyzed for this metric.

Flows that mobilize the median-sized bed material for a given reach do not occur every year, nor must they to maintain river health. Peak flows must be analyzed over various time scales to determine whether flushing thresholds are exceeded often enough (referred to as the return interval), and for enough duration, to maintain river health. For this analysis of peak flows, the period of record from 1976-2016 for each of the three gages was analyzed for peak flow magnitude, duration, and frequency thresholds (Figure 4.1). A longer-term record is needed to compute a return interval and to characterize ecological processes and cycles that occur over long periods (decades to centuries). Looking at this 40 year period is needed to compute a return interval and is appropriate since many ecological processes and cycles occur over much longer periods (decades to centuries). However, long-term patterns do not provide information on the occurrence of recent bed mobilization in this SOPR study period (*i.e.*, 2015-2016).

A second line of evidence helps convey the current condition of the critical ecological functions driven by the peak flows. The embeddedness of riffles, as measured in the fine scale metric (page 70), provides field-based evidence indicating the degree of bed flushing that has occurred recently. Using the fine-scale structure metric alone, without analysis of the longer flow record, could be misleading, since rivers naturally experience climate driven wet-dry cycles that span years to decades. For instance, during a dry period, when flushing has not occurred for several years, the riffles may appear more embedded with fines. Therefore, the SOPR assembled multiple lines of evidence covering multiple time scales to produce a better understanding of the single most driving factor in Poudre River health.



Recent activity of flushing flows is measured in the "**fine-scale"** physical structure metric. See page 70

Figure 4.1: Daily average discharge at the canyon mouth gage (1976-2016) was analyzed for peak flow magnitude, duration, and frequency thresholds. The horizontal orange line indicates flow of 3300 cfs which was calculated in the ERM as the threshold required to mobilize the median grain size in the Rural and Urban zones. Long, medium, and short time scales are considered in the comprehensive interpretation of flushing flow functions. The fine-scale physical structure metric provides another line of evidence to determine whether flushing has occurred in the past few years.

Base flows

Base flow grades ranged from C- to F+. There is a slight downward trend in grades from the Canyon through the Plains zones due to the cumulative depletion of water during low flow periods from the 16 major diversion points located throughout the study area. Depletions during low-flow periods cause lower base flow and/or prolonged periods of low flow (Figure 4.2). Some segments of the Poudre run dry below diversions during winter. Point flow models indicate that at least three days with no flow occur per year, on average, below Greeley's water supply diversion, and occur again at other diversion structures downstream, increasing the number to 24 days of no flow per year at the Fossil Creek Inlet Diversion (see Figure 3.1 and Tables 3.2 and 3.3).

Figure 4.2: Extremely low base flows occur regularly in reach 13.

Rate of change

Rate of change grades ranged from C to C-. Most reaches either contained at least one diversion, or have one in a proximate upstream reach. These diversions are managed such that rates at which flows rise and fall can be rapid enough to stress native plants and animals. Abrupt changes in flow that can occur when diversion gates are suddenly opened and closed can negatively impact the aquatic biota, especially during low flow periods. This metric's scores highlight an important stress on the rivers aquatic ecosystem.

Sediment regime

Sediment regime grades ranged from A- in the Canyon to C+ in the Plains zone, indicating that the sediment regime is largely in good condition (Table 4.3). Impairment of continuity as a result from in-line reservoirs and dams was the most influential downward driver of grades.

Table 4.3: Summary of sediment regime indicator scores and grades organized by zones and reaches.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Land Erosion	82	88	88	92	92	92	92	92	85	85	85	85	85	85	85	85	85	85

	86			82			81							79				
Zone	Canyon			Rural			Urban							Plains				

Land erosion

Land erosion grades ranged from A- to B-. The only significant land erosion stressor in the Canyon and Rural zones is from the land cover change within the burn areas of recent wildfires. Erosion from burned areas affects the Poudre most on the reach between the Munroe Diversion and the confluence with the North Fork. Approximately 16% of the watershed area contributing to this reach is burn scar, and the reach is graded B-. The contributing watershed area more than doubles below the confluence with the North Fork, so the percent burned area in the contributing watershed drops to 7% at this point, yielding a grade of B+. The effects of the fire diminish from this point downstream.

Other stressors from land erosion such as construction disturbance, impervious surfaces, and urban stormwater runoff, become more important in the Urban and Plains zone. Some of these impacts increase sediment runoff, but most of them decrease the supply of sediment. The net effect of land erosion impacts on overall sediment regime on the Poudre is minimal, warranting a grade of B or higher through the Urban and Plains zones. Land erosion is not a critical limiting factor to the health of the Poudre River.

Channel erosion

Channel erosion grades ranged from A to C+. The Canyon zone scored the highest (A) with no significant stressors. The Poudre River is a threshold channel through the Canyon zone, where geologic controls naturally limit the amount of channel erosion. Most of the banks are also armored. Tributary watersheds in the Canyon zone are mostly undeveloped with few to no anthropogenic stressors affecting rates of channel erosion.

In the Rural, Urban, and Plains zones, the Poudre was historically an alluvial channel with river bed and banks that moved and adjusted with natural patterns of erosion and deposition. Artificial stabilization is a major human impact in these zones, where armored banks, riprap, channelization, berms, dams, weirs, and grade control structures have been employed to keep the river in place. Natural processes of erosion, deposition, and migration are severely limited by these treatments. The river through these zones behaves much more like a threshold channel in that erosion and migration occurs only during

extreme events. Most of the time, there is little to no channel erosion and therefore little to no contribution of sediment from channel erosion on these reaches. While the overwhelming trend is towards a stabilized and static river channel with little erosion, there are localized segments with acute channel erosion issues. Some stabilization measures, such as the extensive use of riprap, have accelerated bank erosion in adjacent segments that are not armored, and in some cases failed stabilization efforts have exacerbated erosion.

The same impacts are present on most of the tributary streams that enter the Poudre within the lower zones. Artificially-stabilized streams usually contribute less sediment than they would in their natural state —but in some cases the opposite is true. Channel incision and accelerated bank erosion on a few tributary streams elevate sediment supply above natural levels. Some of these tributaries are streams on which stabilization measures failed. Others evolved into incised channels in response to land and water use practices and are still eroding. Retention ponds on some of these eroding tributaries capture sediment before it enters the Poudre. Overall, sediment supply from tributary reaches has probably decreased compared to natural conditions.

Continuity

In-line dams and reservoirs have the greatest impact on sediment continuity. Reservoirs trap essentially the entire sediment supply from the North Fork basin, which adds up to 54% of the Poudre's contributing watershed area when they join. Because of this impact, sediment continuity scores drop from A to D+ at the confluence, and then gradually increase moving downstream as the sediment-blocked North Fork drainage area becomes a smaller and smaller proportion of the contributing watershed. Other impediments to sediment continuity such as small in-line dams and diversion structures may be insignificant to sediment continuity because the volume of sediment trapped and stored is small compared to the annual yield and these structures are likely filled to capacity with sediment.

Water quality

When averaged across the entire study area, water quality on the Poudre River was graded B, indicating a highly functional condition, with reach scores ranging from B+ to C+ (Table 4.4). Local impairment issues are apparent, however, when the river is assessed at finer resolution. At the B grade, water quality may be impaired enough to affect the distribution and community assemblage of aquatic life, but it is still supporting essential functions well. Stressors to water quality are mostly managed or mitigated.

Table 4.4: Summary of water quality indicator scores and grades organized by zones and reaches.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18

	80			83			88							87				

Issues with temperature and dissolved oxygen concentration are the most important downward drivers on water quality and its grade. The higher water quality grades in Urban zone versus the Canyon zone may seem contrary to expectations, however, the grading criteria are set relative to water quality standards, which vary as the river changes in character. Therefore, grades relate to a correspondence with standards rather than some absolute measure of water "purity". Nutrient levels downstream of I-25 may be elevated enough to affect biological function, specifically in respect to potential changes in algal productivity and/or algal species composition in the river (a "reach 19"—downstream of the study area—was evaluated for certain water quality measures as explained below). Water treatment and ongoing active watershed management are critical to mitigate potential water quality issues and support aquatic life in these reaches below the study area.

Water temperature

Water temperature grades ranged from A- to D+. The reach upstream of the North Fork in the Canyon zone (reach 1) was graded B. Although this reach is part of the CDPHE Stream Segment 10a, which is on the state 303d list of impaired waters for temperature, an evaluation of temperature records showed that state temperature standards were not exceeded on this specific reach between 2013 and 2015. Below the North Fork confluence on reaches 2-4, however, several exceedances of the acute maximum daily temperature standard were observed over the same period, as well as exceedances of the chronic standard, maximum weekly average temperature (MWAT). These data confirm the 303d listing for this portion of Segment 10a for temperature issues, resulting in a D+ grade. Although seasonal average temperature (Apr-Oct) is within the B range, a 303d listing automatically confers a grade of D or less by RHAF grading guidelines.

The D+ grade and water quality standard exceedences for reaches 2-4 must be interpreted with broader perspective, otherwise these measures may convey an incomplete and potentially misleading picture of

river health within these reaches. In general, maximum daily temperature standard exceedances occurred during two times of the year, in late March and in the summer months from June - September. Temperature standards change abruptly from cold to warm season values on April 1. It is usually during this time of year, known as the shoulder season, when warmer air temperatures begin to increase water temperatures, and exceedances may occur depending on the timing and magnitude of the spring warm-up period. Summer exceedances occur during particularly warm years, and/or when river base flows are low. Regardless of the timing of the standard exceedances, the data record indicates they are generally infrequent and of short duration. For the large majority of the time during the years 2013-2015, temperatures are well within the standards. The exceedances, do however, highlight the importance of continued temperature monitoring for both aquatic life and water quality perspectives, as increases in the frequency and magnitude of exceedances may signal the presence of anthropogenic stressors, or climatic trends toward hotter and drier summers and earlier spring snowmelt, both of which could have considerable impact on overall river health and function.

The exact causes of the observed standards exceedances in reaches 2-4 are currently unknown, although a variety of factors may act together to result in relatively warmer water temperature in the river including the proportion of North Fork and Mainstem Poudre flows, overall river flow volume, diversions and inflows, in-channel reservoirs and weather. Figure 4.3 further illustrates the higher temperatures in reaches 2-4, as compared to upstream and immediate downstream reaches.

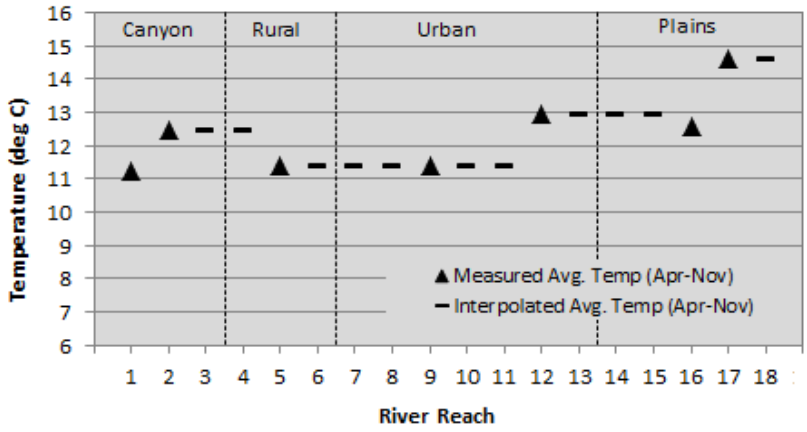

Figure 4.3: Reaches 2, 3 and 4 of the Poudre showed warmer temperatures than upstream and immediate downstream reaches, as shown in this graph of 2015 average temperatures by reach for the months of April – November, 2015.

Water temperature grades improve to B in reach 5 of the Rural zone, just downstream of the 303d-listed segment. This segment receives cold-water discharge from Horsetooth Reservoir via the Hansen Supply Canal which may mitigate some of the higher temperatures that drive exceedances in the river upstream. According to CDPHE Regulation #38, the river transitions from a cold-water to a warm-water designation at Shields Street, between reaches 8 and 9. Since water temperature standards are based on excessive heat, the warm-water designation at this point means that standards below Shields Street

are warmer. While water temperature continues to increase through the Urban zone, the improved grades (A-) on reaches from Shields to Mulberry are more a reflection of the change in designation from cold-water to warm-water and the less-stringent standards that go with it.

Both cold and warm season average water temperatures increase gradually downstream through the Urban and Plains zones, and this trend is reflected by a corresponding decrease in grades from A- to B for reaches from Mulberry to I-25. Increasing temperature may be attributed to the cumulative effects of decreased streamflow due to diversions, as well as inputs of treated wastewater effluent and urban stormwater runoff, which are usually warmer than river water. Temperature monitoring east of I-25 indicates that the warming trend continues downstream below the study area.

Nutrients

Nitrogen and phosphorus monitoring reveals little to no nutrient impairment anywhere in the study area. Grades for the nutrient metric (average of nitrogen and phosphorus grades) are in the A to B range, indicating reference standard to highly functional condition throughout— though there is a slight downward trend through the Urban and Plains zones. The slight increase in nutrient enrichment on the lower reaches is likely due to return flows from irrigated and fertilized areas within the urban and residential developments, agricultural runoff, and treated wastewater effluent.

Consistent with other indicators and methods employed in this SOPR assessment, water quality conditions are evaluated and reported for the 18 reaches of the study area, which ends where the Poudre River crosses I-25. However, it is recognized that the influence of the City on water quality is not fully represented by this geographical scope. It was, therefore, determined that water quality would be evaluated further east of I-25, below the point where discharge from Fossil Creek Reservoir enters the Poudre, as this location includes the return of local communities' reclaimed wastewater to the River. Although presentation and discussion of results throughout this report include only the common 18 reaches, where notable, water quality results for the additional site, termed reach 19, are included.

Within reach 19, measured nitrogen concentration was in the C range, and measured phosphorus was in the F range, resulting in a combined nutrient metric grade of a D for this reach. Given the drastic increase in nutrients at this station, and the lack of any other apparent stressors, Fossil Creek Reservoir discharge is the most probable cause of nutrient loading. The water quality in Fossil Creek Reservoir reflects the combined influences of Poudre river water, reclaimed municipal wastewater, local stormwater runoff, and seasonal reservoir dynamics. Total phosphorus concentration at this site exceeded CDPHE's proposed warm-water standards of 170 µg/L (based on Colorado's Water Quality Control Commission Regulation #31—The Basic Standards and Methodologies for Surface Water) more than once over the last five years. If CDPHE formally adopts the 170 µg/L phosphorus standard, this section of the Poudre will be considered impaired due to nutrient loading.

pH

Measured pH values were within normal ranges (6.5 - 9.0) at all stations during the monitoring period, indicating no functional impairment on any of the study reaches. Grades ranged from A- to B+, owing to

slight variations and occasional readings at the margin of the A-grade range. The grade decreased slightly to B downstream of Fossil Creek Reservoir outlet in reach 19, reflecting the influence of wastewater effluent and/or discharge from Fossil Creek Reservoir on river water quality.

Dissolved oxygen

Grades for dissolved oxygen were A- to B, and all sites met the water quality standard for spawning fish. Most sites throughout the study area scored a B+, but the lowest two reaches in the Plains zone (17 and 18) scored a B. These reaches on the river have the lowest seasonal flow conditions and receive warmer, nutrient-rich water from two upstream wastewater reclamation facilities. These inputs can reduce dissolved oxygen concentrations in the river water when biological oxygen consumption from metabolism and aerobic decomposition outpaces oxygen production from photosynthesizing aquatic plants and algae. Other stressors that may decrease dissolved oxygen concentrations include a lack of turbulence or physical mixing, stagnant water, elevated temperatures, and the accumulation of fine sediment that further increases oxygen demand. Dissolved oxygen concentrations drop further into the B- range in reach 19, below the confluence of Fossil Creek.

Floodplain connectivity

Overall, the floodplain connectivity indicator received a C grade (Table 4.5). Only one metric (floodplain extent) influenced this grade, as discussed below.

Table 4.5: Summary of floodplain connectivity indicator scores and grades organized by zones and reaches.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Floodplain Extent	78	82	85	74	65	85	62	61	87	50	67	73	70	77	50	98	82	71
Floodplain Connectivity	78	82	85	74	65	85	62	61	87	50	67	73	70	77	50	98	82	71
	81			75			68							79				

Floodplain extent

The floodplain extent metric considers the physical (topographical) connection between the river channel and its floodplain and the frequency at which flows inundate the floodplain. Conditions vary considerably through the study area, resulting in a wide range of scores. In the confined Canyon zone, there is limited natural floodplain, and connectivity depends almost entirely on the degree to which road fill for Highway 14 encroaches on it. Diversion dams and bridges are additional physical factors affecting floodplain connectivity where they consolidate flows between wing walls and over spillways. The river in the Rural, Urban, and Plains zones is not geologically confined and, historically, the natural floodplain area was up to two miles wide in places. Over time, however, that width has been deliberately decreased—through berms and channelization—to make use of the floodplain for a variety of purposes.

Floodplain connectivity is a keystone indicator because it is a fundamental requirement for a functional and resilient riparian habitat (Figures 4.4). An undeveloped floodplain that is well-connected to the river is critical for maintaining riparian habitats and dissipating potentially damaging flood energy. A healthy and resilient river needs an effective channel migration zone within which the river can move and adjust to disturbance. The C and C+ grades for floodplain connectivity on the Rural and Plains zones indicate a an impaired, but still modestly-functional floodplain. The D+ grade for the Urban zone highlights the legacy of land uses in the floodplain, many of which are difficult (or slow and costly) at best to rectify. The reach-scale grades vary considerably with most reaches scoring from B+ to D. Two reaches scored F, indicating a profoundly impaired and non-functional condition. Reaches with low grades for floodplain connectivity also tend to have poorly functioning riparian areas and low capacity for resilience (Figure 4.5).

Figure 4.4a: The five-year water surface extent between College Ave. and Lincoln St. (reach 10) shows an entrenched channel with limited floodplain connectivity due to natural bedrock and constructed berms.

Figure 4.4b: The five-year water surface extent from the Woodward campus to upstream of the Timnath Canal Diversion (lower end of reach 11 and upper half of reach 12) shows a less entrenched channel with a better-connected floodplain.

Figure 4.5: Floodplain connectivity is critical for river health, and it also reduces risk to infrastructure. During extreme high flow events, where floodplain-river connectivity is poor and development in the riparian zone is extensive, there is greater risk of flood damage to infrastructure. The photograph at left shows a connected floodplain at a former golf course (currently the Woodward site and Homestead Natural Area). Near the bottom left of the photograph, however, the intersection of Lemay Avenue and Mulberry Street limits floodplain connectivity and floodwaters threatened to over top Lemay Avenue. In contrast (right), at the ELC, the riparian zone is managed for natural habitats and the topography allows for the river to be connected to the immediate zone next to the river, resulting in a resilient situation

Riparian condition

Vegetation structure is the primary metric informing the riparian condition score, with the other two metrics of habitat connectivity and contributing area exerting a relatively smaller influence. The riparian condition indicator scores varied from B to D indicating that all reaches still maintain at least a rudimentary riparian zone (defined as the corridor extending 100m from each bank) (Table 4.6).

Table 4.6: Summary of riparian condition indicator scores and grades organized by zones and reaches.

Zone	Canyon (100 ac.)			Rural (449 ac.)			Urban (571 ac.)							Plains (427 ac.)

Zone Canyon Rural Urban Plains

Vegetation structure

The vegetation structure assessment considered various factors needed for sustainability and resilience of riparian habitat such as land use and cover type, habitat patchiness and interspersion, diversity in height structure, presence of problematic non-native species, and regeneration of native tree species. The reach scores are informed by the composite scores of individually-mapped patches or "polygons." The assessment was conducted at the patch level and averaged across each reach. There was often diversity in scores across the patches within a reach, with forested patches tending to have higher scores than non-forested ones.

Vegetation structure grades range from B to D with a strong demarcation of scores between reaches secondary to changes in land use and land cover and degree of connection with the river. Vegetation is absent or greatly altered in large portions of the historical riparian zone. In cases where no appreciable vegetation was present, the assigned grade was an F. Patches with vegetation structure more closely resembling natural conditions scored higher. Land cover determines the potential to support healthy riparian habitats. For the analysis, land use and land cover were the first filters to determine grading and also to identify candidate patches for field assessment. Appendix D provides the results corresponding to these classes, along with a basic description, a summary of grades, and the relative cover of each class.

Patches of quality riparian habitat may be present even on reaches with low vegetation structure scores (Figure 4.6a and b). Remnant patches of forest, scrub-shrub, and wetland are commonly embedded in more developed landscapes, especially on City of Fort Collins Natural Areas parcels. Remnant patches of high-quality riparian vegetation may have positive habitat benefits that exceed their contribution to overall reach scores since they provide urban habitat oases and refugia (Figure 4.6a and b).

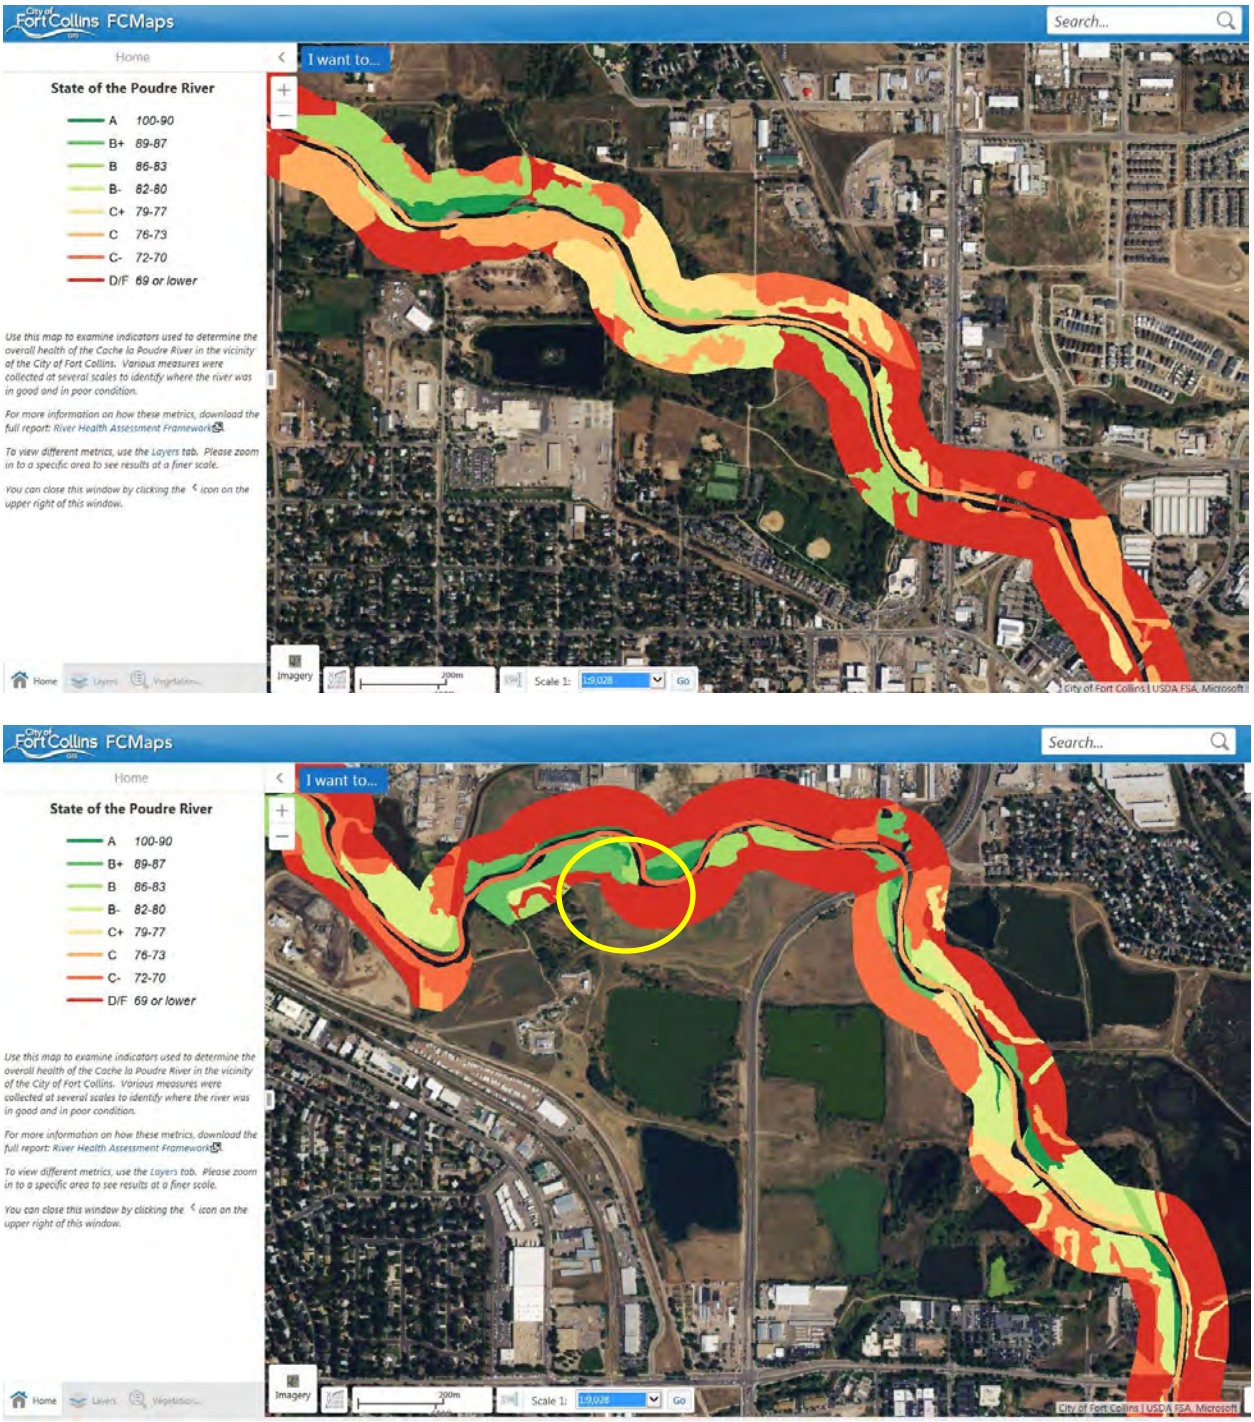

Figure 4.6a and b: Images from the SOPR online mapping tool illustrate how patches of naturalistic riparian vegetation provide high quality habitat amidst otherwise developed areas. The top image shows Shields Avenue to Linden Street in downtown Fort Collins (reaches 9, 10, and 11). The bottom image shows the river above and below Timberline road (reaches 12, 13, and 14). The primary driver of vegetation structure is connectivity with river flows which is particularly poor in the areas from College Avenue to Linden Street (bottom right Figure 4.6a). The yellow circle on Figure 4.6b shows the location of the photograph shown in Figure 4.7

Figure 4.7: A highly functional riparian forest can be adjacent to very poor-scoring riparian zone. This location of this photograph is provided in Figure 4.6b.

Eight sub-metrics were used to grade vegetation structure of patches with natural cover types such as forests. A majority of the field-graded habitat patches (especially within the Urban and Plains zones) are located on public lands managed by the City of Fort Collins (Natural Areas or Parks Departments) or CSU.

Comprehensive results for all polygons for all submetrics are also presented in Appendix D. As well, comprehensive results are presented for public lands only that are owned and managed primarily for conservation of natural habitats (like the City of Fort Collins Natural Areas.)

Vertical Complexity

Vertical complexity of wooded patches was graded B, on average, indicating highly functional condition with minor impairment. Wooded habitat typically has three layers of vegetation: herbaceous, shrub, and tree and all of the patches evaluated had at least two vegetation layers. When a stratum is missing, it is usually the shrub layer. There are several reasons for the loss of shrubs in forests. Primary causes are agriculture or landscaping, hydrologic alteration, overgrowth of crack willow that results in large

patches of shaded areas for long periods of time, and lack of natural physical disturbance that maintains and renews shrub populations.

Canopy species

Native cottonwoods are most commonly the dominant canopy species, although crack willow sometimes dominates and is often the second most -common species. The average score for canopy species submetric in canopy forest patches is B.

Sub-canopy species

Sub-canopy composition also generally leans toward a native-dominated composition, with exotics such as Chinese elm and crack willow commonly next in frequency. An increasing presence of green ash is observed in the Urban and Plains zone. While this species is considered native, it is likely to alter the trajectory of these forests and their future composition, but exactly how is not well understood yet. Grades for the sub-metric are B, on average, in the Canopy and Sub-canopy Forest patches, while scrub-shrub sub-canopies grades average C+.

Figure 4.8: Canopy and subcanopy dominated by native cottonwoods and associated desirable "vertical complexity" are observed adjacent to the multi-use Poudre Trail at Lions Park in the Rural zone.

Shrub layer

The shrub layer is significantly diminished in riparian forest habitats along the Poudre (as explained above), but where it exists it is still usually a functional stratum with grades of C to C+. In scrub-shrub cover class the stratum tends to be in outstanding condition (A) — being dominated by a dense coverage of native sandbar (aka, coyote) willow. Scrub-shrub habitat has become limited in distribution, however. Almost all of the scrub-shrub habitat patches are immediately adjacent to the river where a narrow band of fluvial disturbance along the channel still supports willows and other shrubs that require the bare ground and wet conditions to reproduce and establish. Areas farther away from the stabilized river channel are only exposed to fluvial disturbance during extreme flood and they tend to be dry, and are therefore not conducive to shrub establishment.

Problem herbaceous species

Problem herbaceous species are a significant cause of impaired function on some riparian habitat types. Canopy forest, sub-canopy forest, and scrub-shrub patches scored in the B to C+ range, while emergent wetlands averaged C-. In wooded habitat, reed canary grass, Canada thistle, and leafy spurge are the common problem herbaceous species, but infestations are rarely extensive. Broad-leaved cattail,

a common problem species, dominates most of the emergent wetland adjacent to the Poudre, often to the near exclusion of other herbaceous species.

Problem woody species

Problem woody species are not a major issue on most wooded riparian habitat along the Poudre, and scores for this sub-metric averaged A- to B. Crack willow is not considered a significant problem where it is only present occasionally, but it is a problem where it forms homogenous thickets or dense, impenetrable forest canopy. It is by far the most common problematic woody species yet its impact on function can be both positive - for instance as it provides bank stabilization- and negative when it significantly limits resources available for native species. Tamarisk—an invasive species that is common in neighboring watersheds— was only observed in one small stand of a few individuals at the ELC. Russian olive, an invasive tree species, occurs throughout the Rural, Urban, and Plains riparian zones, but extensive eradication efforts over the past decade by the City of Fort Collins has been effective such that very infrequently is it dominates the forest sub-canopy.

Patchiness and interspersion

Results for patchiness and interspersion follow a similar pattern to those for vertical complexity. In wooded habitats the average grade is B-. Decreased patchiness is often the result of direct impacts such as tree and shrub removal, land clearing, or development. Riparian vegetation structure has also become homogenized due to an altered disturbance regime and a reduction in system dynamism. Much of the river is artificially stabilized so that the natural meandering, avulsion, and deposition processes that would normally drive plant succession, diversity, and forest regeneration have been lost. Wetland emergent habitats usually have poor patchiness and interspersion because most of them have become overgrown by cattails.

Native tree species regeneration

Regeneration of native tree species—particularly cottonwoods— has been substantially curtailed by effects of water management and disconnection of the river from its floodplain. Owing to various floodplain alterations, such as channelization and berms, the opportunity for establishment of native trees has been limited, but it does still occur and it was common in forested and subcanopy patches (Figure 4.9). In cover types where native tree species regeneration would be expected—including canopy and sub-canopy forest, scrub-shrub and emergent wetland—this metric averaged a C, ranging from D+ in wetlands to B- in scrub-shrub patches. Regeneration was good in scrub-shrub patches because they tend to be near the channel and exposed to overbank flows. [Note that the lack of tiny seedlings or very young saplings was not taken to indicate a lack of regeneration, because regenerative floods are relatively uncommon events. Therefore, the main criterion for judging regeneration was the presence or extent of a multi-generational age structure.

Figure 4.9: Germinating cottonwood seedlings established readily at McMurry Natural Area when physical connectivity was restored such that annual spring flows provided basic habitat conditions.

Floodplain position

This sub-metric uses the floodplain position patch classification, which includes three categories: riverine, depressional, and terrestrial. Sixty-two percent of the riparian zone is riverine, meaning that is still effectively connected to the river. Eleven percent of the floodplain is now depressional (*i.e.,* mostly gravel ponds) and disconnected from the river by berms. The remaining 27 percent of the riparian zone has been terrestrialized and isolated from the river, except perhaps during the largest flood events.

Habitat connectivity

The habitat connectivity metric is a measure of the degree to which riparian habitat is biologically connected with surrounding riparian habitat, or conversely, the degree to which habitat has become fragmented or isolated. Habitat connectivity ranged from an A- in the Canyon zone and ELC to a D- in the heart of the Urban zone. While D- indicates very poor connectivity, it also signals that connectivity has not been totally eliminated. Organisms can still move throughout the entire study area, even if rates of movement may be greatly reduced through the urban bottleneck). Connectivity has been fairly well preserved upstream and downstream of the developed urban areas, and even in the Urban zone there are islands of good-quality riparian habitat that provide refuge to the animals that do make it through dangerous and stressful areas (Figure 4.10).

Contributing area

This metric reflects the level and type of land-use change that has occurred in the area surrounding the riparian corridor. Certain land uses, such as parks, still have some positive benefit as buffers between

riparian habitat and developed areas. Riparian areas directly in contact with more intensive land uses such as urban development, on the other hand, are adversely affected. Reach-scale contributing area metric grades from A- to D- roughly parallel scores for habitat connectivity since contributing area is affected by the same types of land-use stressors. Generally speaking, the contributing area is in fairly good condition, reflecting the rural uses surrounding most of the riparian zone. The obvious exception to this is in the Urban zone, where the contributing area has a generally negative effect on river health.

Figure 4.10: The presence of mink along the Poudre near is an indication that the food webs they rely on as predators (and associated habitats of their prey) is fairly intact.

River form

On the reach scale, river form grades ranged from a D to a B-, averaging a C for each zone (Table 4.7). Planform shape of the river was the most impaired of the three metrics, while cross-sectional profile was the least. The planform shape of the river has generally been straightened and simplified through channelization and armoring. The other two metrics of river form have often been able to adjust, at least in part, to the newly derived planform shape.

Table 4.7 Summary of river form indicator scores and grades organized by zones and reaches.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18

	76			76			73							73				

Planform

Planform describes the river's form in terms of length, sinuosity, meander patterns, and branching. Reach-scale planform grades range from C+ to D- with the lowest score occurring in the channelized, heavily riprapped, and bermed reach between College Avenue and Lincoln Street. At the sub-reach scale, scores range from A- to F (Tables 4.8a and b). The highest scores are on reaches that are not channelized or stabilized by armored banks, grade control, or bridge crossings. On these reaches, the river is able to meander naturally and adjust its planform in response to changing boundary conditions. The lowest scores occurred on channelized reaches with diversion structures, bridges, and heavily armored banks.

The Poudre River is channelized through most of the Rural, Urban, and Plains zones. The naturally complex, meandering, braided, and branched channel form has been simplified to a much straighter and single-threaded channel form which is maintained with berms, riprap, and grade control structures. It has essentially been converted from a dynamic "alluvial" river system—one that would naturally move and adjust in a gradual fashion—to a "threshold" system that is artificially locked into place and can only move or adjust catastrophically when stabilization measures are overwhelmed during extreme events.

When the river does overcome stabilization measures, and it begins to meander or form branch channels, it is usually reconstructed into its artificial, single-channel form. Lyons Park is a prime example of this back-and-forth pattern. During the 2013, flood this section of channelized river eroded through its armored bank and migrated 50 feet laterally to increase sinuosity and decrease slope. Within two years the river channel was returned to its pre-flood position, and the bank was backfilled and re-armored. In most cases, maintaining the present channelized and relatively straight single channel river planform is necessary to protect infrastructure and development, but this generally has negative impacts on river form, function, and resilience.

In some cases the channelized and straightened river form may have arisen due to a combination of natural and anthropogenic reasons. On the ELC in the Plains zone, approximately 3100 feet of the river became straightened when it avulsed into a large ditch on the floodplain in the 1990s (Figure 4.11).

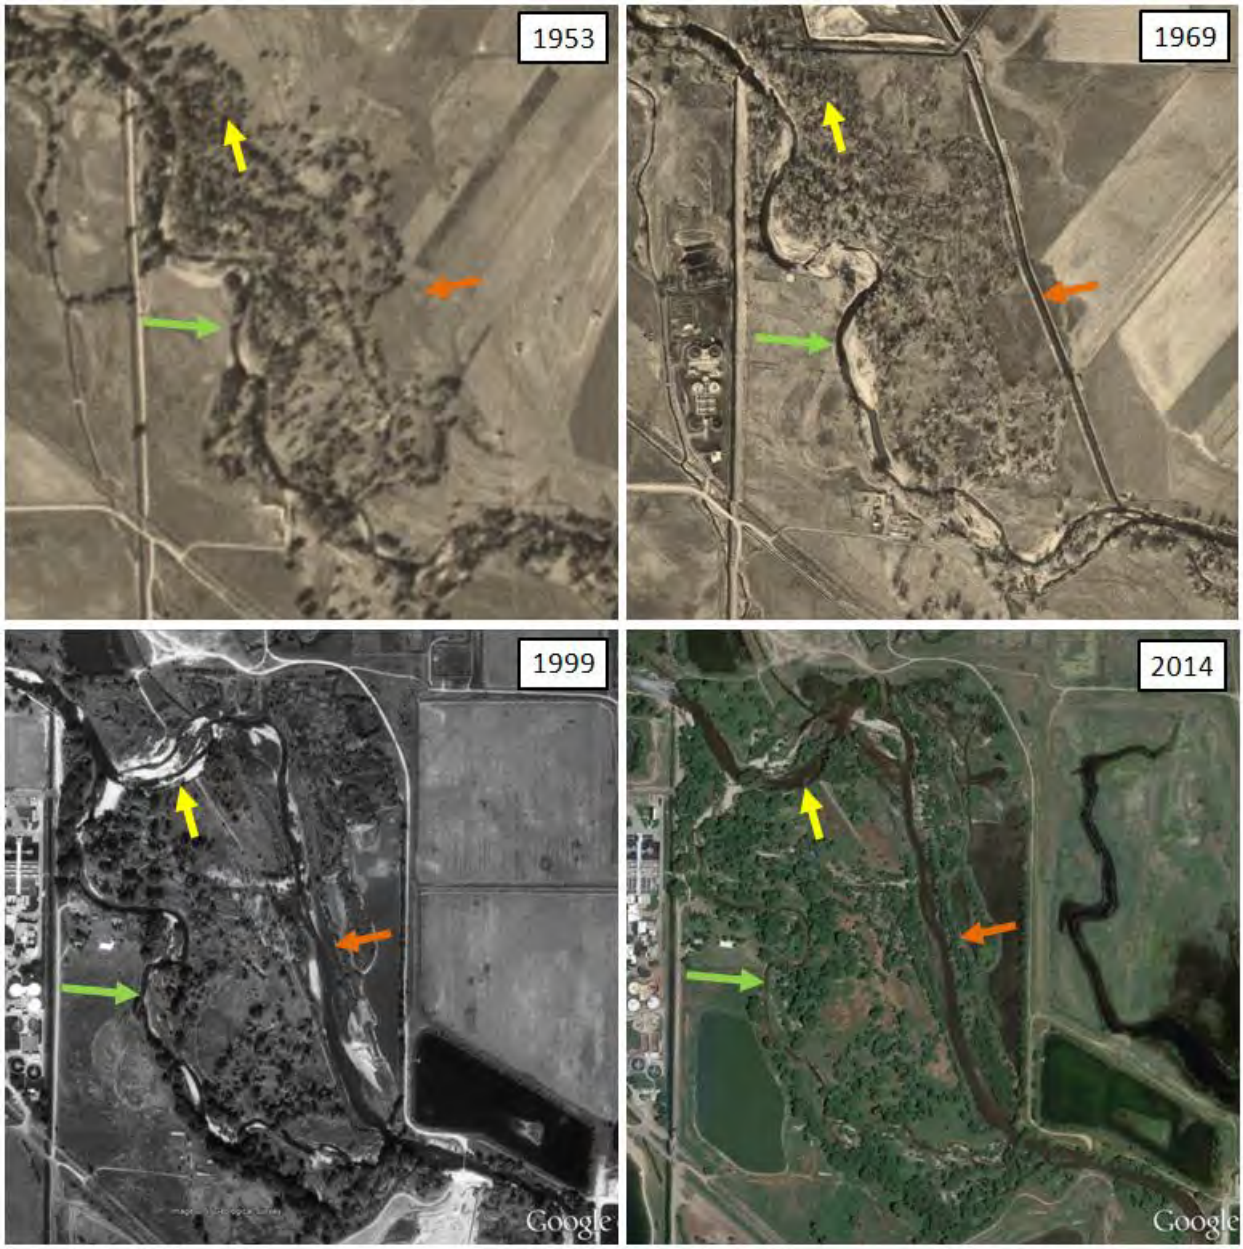

Figure 4.11: The straight single-channel planform of 3100 feet of the Poudre River on the Environmental Learning Center was formed in the 1990s when the river cut into and started flowing through a large floodplain ditch, abandoning its historic sinuous alignment. The time sequence of aerial photos shows the historic channel alignment (green arrow), avulsion point (yellow area), and current alignment through the ditch (orange arrow).

Table 4.8a: Chart showing grades of the geomorphic metrics and indicators in the two upper study zones. Colors corresponding to metric grades are shown for each of the 99 sub-reaches. Colors corresponding to indicator grades are shown for the 18 reaches. Bar lengths are scaled to the actual length of reaches and sub-reaches. Segments affected by floodplain encroachment, bank/channel armor, and bridge or dam structures are also shown.

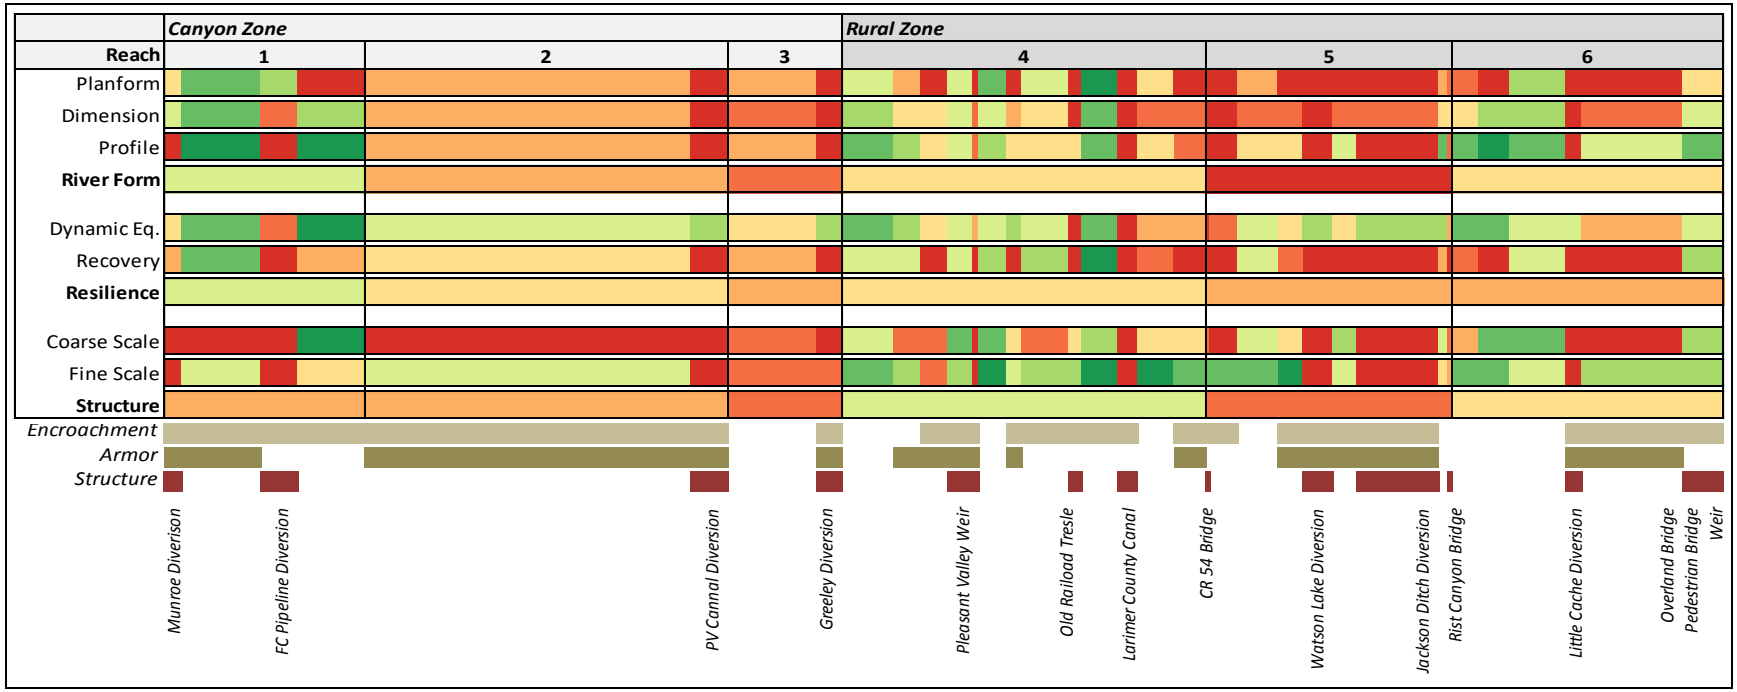

Table 4.8b: Chart showing grades of the geomorphic metrics and indicators in the two lower study zones. Colors corresponding to metric grades are shown for each of the 99 sub-reaches. Colors corresponding to indicator grades are shown for the 18 reaches. Bar lengths are scaled to the actual length of reaches and sub-reaches. Segments affected by floodplain encroachment, bank/channel armor, and bridge or dam structures are also shown.

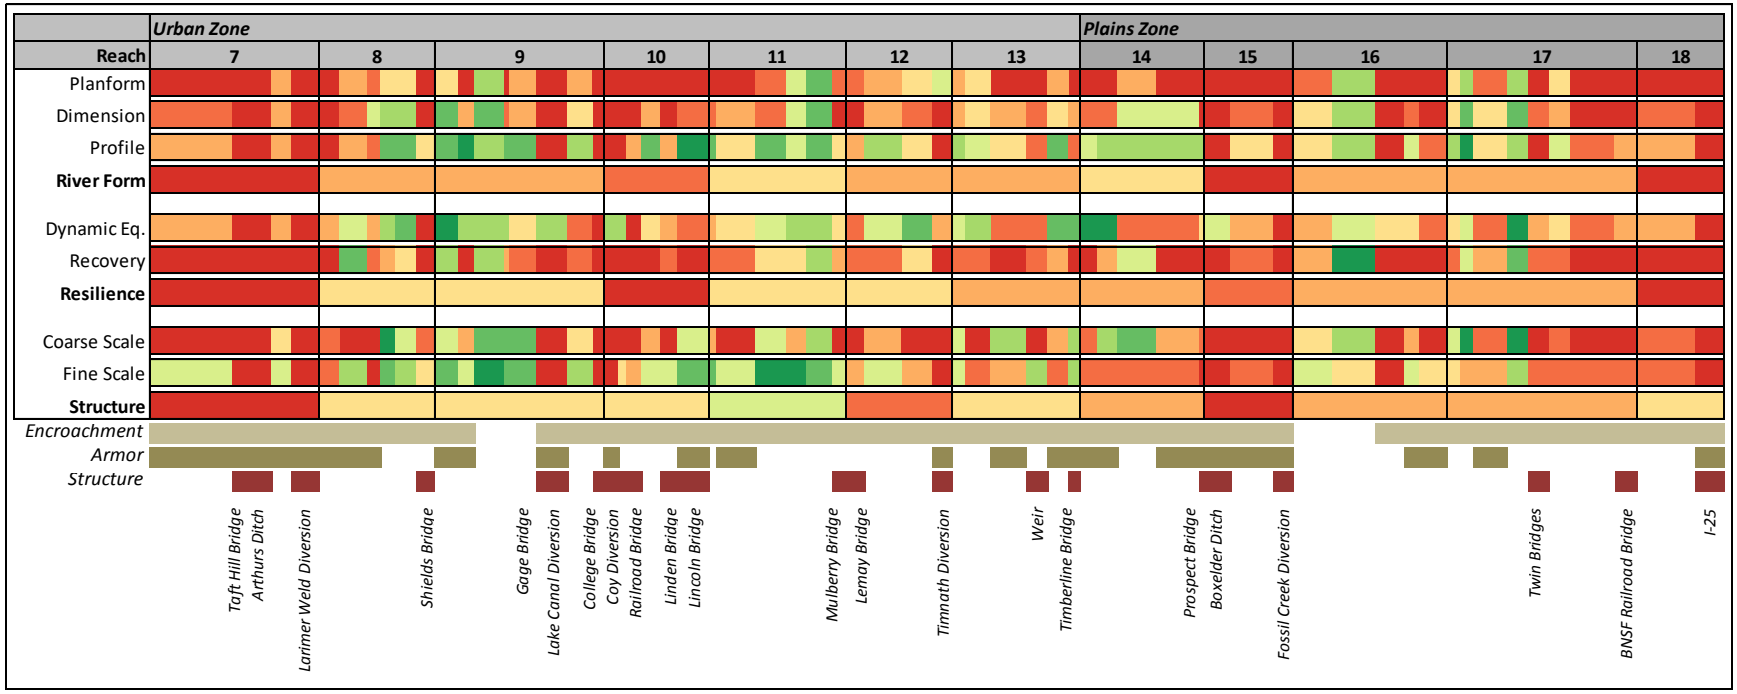

Dimension

Dimension defines the cross-sectional size and shape of the river channels and floodplain. Dimension grades range from B to D over the 18 reaches, and sub-reach grades range from B+ to F (Tables 4.8a and b). The farthest upstream reach, from Munroe Diversion to the North Fork, scored highest, as there are few stressors directly affecting channel dimension in the geologically-confined canyon setting. Downstream of the canyon, increasing channel modification and direct impacts increase entrenchment, channel volume, and width-depth ratio to varying degrees. The lowest grades occur at channel structures such as diversion weirs, dams, and bridges where the channel is often moderately entrenched, enlarged, and either over-wide or over-deep. Berms, and elevated road grades and pedestrian trails along the river disconnect it from its floodplain, creating moderately to severely entrenched channel conditions. In most of the channelized reaches, the active channel dimension has been greatly enlarged to accommodate peak flows and floods. This means that during most of the season, low flows are spread thinly and discontinuously over wide channel bottoms.

Profile

Profile describes the longitudinal slope of the river bed. At the reach scale, grades for profile range from B to D, and sub-reach grades range from A to F- (Tables 4.8a and b). Channel profile is altered by changes to planform shape and in-channel structures. On the reaches in the Canyon zone, river sinuosity is unchanged, but many of the Rural, Urban, and Plains zone reaches have been channelized and straightened. Decreased branching and sinuosity leads to an overall increase in slope over the length of the river. Therefore, the river is steeper than it was naturally, but most of the increased gradient occurs over very short segments at the drops below diversions dams and grade control. Every diversion weir and dam acts as a grade control structure that creates a flattened bed slope upstream and a sudden steep drop below.

The lowest grades for the sub-reaches are often just above diversions. Sub-reaches with the large diversion dam structures such as the Larimer-Weld Diversion and Cache la Poudre Reservoir Inlet Canal score in the F range, indicating severe changes to profile represented by long segments of very low gradient bed slope upstream and steep drop of four to eight feet or more on the downstream side of the structure. Grade control at most of the major bridges has a similar—though less extreme—effect. The lowest-scoring reaches are reach 5 from County Road 54 to Rist Canyon Road in the Rural zone, and reach 15 from Prospect Road to Fossil Creek Reservoir Inlet Ditch on the Plains zone. Both of these reaches have multiple large diversion dams and bridges that create an artificial stepped-slope river profile.

Resilience

In the four zones resilience indicator zone grades ranged from B- to C and for the 18 reaches the grades ranged from B- to D (Table 4.9). Dynamic equilibrium is at least functional along the entire SOPR study area and half of the reaches fall in the highly functional B range. Score for the recovery metric, on the other hand, ranged from C+ to D-, and this metric drove down the overall resilience indicator score. Recovery potential was low mainly because of the reliance on artificial channel stabilization. When artificial stabilization measures do ultimately fail, it leaves the system in such a state that it has little chance of recovering to a healthy and stable state on its own.

Table 4.9: Summary of resilience indicator scores and grades organized by zones and reaches .

Zone	Canyon			Rural			Urban							Plains

Zone Canyon Rural Urban Plains

Dynamic equilibrium

Dynamic equilibrium is a component of stability that depends on the balance of sediment supply and river energy. Excess sediment supply or decreased energy leads to accumulation of material—a process known as aggradation. Decreased sediment supply or increased energy leads to excess scour and erosion that can cause channel incision and/or widening. In the Canyon zone, the Poudre is a threshold river which means that sediment transport capacity, a function of energy, is much greater than sediment supply. Dynamic equilibrium is not normally important for maintaining stability on these types of reaches since it is maintained by a resistant bed and banks of bedrock and boulders. Decreased grades for dynamic equilibrium on the Canyon zone reaches, therefore, reflect acute impacts to sediment transport capacity from in-line dams that cause sediment to aggrade upstream.

Downstream of the Canyon, in the Rural, Urban, and Plains zones, the Poudre was historically an alluvial river. Alluvial river channels are not held in place by naturally-resistant bed and banks—rather, the bed and banks consist of material that can be moved by the river. They naturally move and change shape due to scour and deposition processes. Dynamic equilibrium is normally very important for maintaining stability on alluvial rivers, as the balance between sediment supply and river energy is what maintains proper size and shape. Although the river was historically an alluvial channel in these zones, it is now mostly functioning as a threshold channel due to artificial channelization and stabilization. Grade control structures and bank armor are the resistant features that hold the river in place on many reaches, rather than natural geological features or dynamic equilibrium.

Grades for dynamic equilibrium on the Rural, Urban, and Plains zones generally reflect the degree to which the reach depends on artificial structure to maintain stable form. Reach grades are B- to C- and sub-reach grades range from A- to F+ (Tables 4.8a and b), reflecting the degree to which existing channel configuration maintains sediment transport in the existing flow and sediment regime without either

aggrading or degrading. Grades in the A-B range indicate reaches where the alluvial dynamic equilibrium processes are still functioning. Most reaches are in the C range, indicating the presence of moderate to severe stressors such as channel incision and/or widening that is mitigated with bank armoring and/or grade control structures.

Recovery potential

The recovery potential metric rates the ability of the river system to recover from major disturbance. The predominant factors are (1) whether the river has a sufficiently-wide floodplain and channel migration zone within which it can move and adjust unimpeded by artificial structure, and (2) whether the riparian zone is in sufficiently good condition to support rapid natural vegetation recovery. Sub-reach grades have a wider range, from A- to F- (Tables 4.8a and b). Failing grades indicate sub-reaches that depend entirely on artificial stabilization, engineered structures, or routine maintenance to maintain functional condition, and have no capacity to recover naturally if these fail. In these areas, severe infrastructure damage or safety risks are often the probable consequences of bank failure. A serviceable channel migration zone and the potential for natural channel recovery are virtually nonexistent on these segments.

Scores in the C to D range indicate some potential for recovering function after disturbance, but direct intervention would probably be needed for recovery to occur in a reasonable amount of time. These river segments have significantly diminished channel migration zones, obstructions to physical movement and adjustment, and limited vegetation cover due to a lack of local source material, dispersal barriers, impediments to establishment, or presence of exotics. Infrastructure and human safety are at risk in major events. The important factors limiting recovery potential are: encroachment onto floodplains, channel migration zones, and riparian areas by berms, development, and infrastructure. Infrastructure in the river itself such as dams and bridges are particularly influential drivers of river health and the scores for this metric specifically.

Reach-scale grades ranged from C+ to D-, however, it is important to recognize that the major impediments to recovery that result in failing grades occur on short sub-reaches in association with sub-reaches that are less impaired. Since reach scores are calculated as the weighted-average sub-reach scores, the short, high-risk segments are averaged with low-risk segments within a reach, which tempers the grade at the reach scale.

Physical structure

The physical structure indicator ranged from B- to D across the 18 reaches and averaged C to C- across the four zones (Table 4.10). Coarse-scale structure was in poorer condition on most reaches (relative to fine-scale), with grades ranging from B- to F; only one reach was in the B range. Except in two reaches in the Plains zone, fine-scale structure was always at least in the C range and almost half the reaches were in the B range.

Table 4.10: Summary of physical structure indicator scores and grades organized by zones and reaches.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Coarse-scale	76	67	70	78	70	75	59	74	77	73	75	65	77	80	60	73	73	68
Fine-scale	76	80	72	85	74	83	72	80	80	81	87	74	77	72	65	74	75	69
Physical Structure	76	74	71	82	72	79	66	77	79	77	81	70	77	76	63	74	74	69
	74			78			75							72				

Coarse-scale structure

The fundamental shift in river dynamics from alluvial conditions to an artificially-stabilized threshold channel through most of the study area has significant ramifications on coarse-scale physical structure, affecting the diversity of characteristic depth-velocity combinations and physical features. The natural processes that maintain structural diversity on dynamic alluvial rivers such as lateral bend scour, bar deposition, and accumulation of large woody material are rarely present on channelized and artificially-stabilized reaches. Structural diversity on these impacted reaches depends on artificial material and engineered features. Patterns in sub-reach grades for the coarse physical structure metric, which range from A- to F- (Tables 4.8a and b), generally correlate with the degree of channelization, but acute impacts from in-channel dams and diversion weirs are also an important factor. Dams and weirs create flat slack water where sediment accumulates and scour is limited, resulting in structural homogenization at both the coarse and fine scale.

Sub-reaches with failing grades have severely homogenized structure in the form of glide habitat caused by in-line diversions. Sub-reaches scoring in the D range lack some characteristic depth-velocity combinations or structural elements at most flow levels. In most cases, structural homogenization on these segments is caused by artificial stabilization, low scour potential, and lack of large woody material in the river. Despite the widespread impacts of channelization, channel and bed armoring, in-stream structures, and impaired flow regime, some sub-reaches are less impacted and still maintain a high degree of structural diversity due to natural or artificial mechanisms. Less developed segments in between diversions in the upper part of the Rural zone have highly functional coarse physical structure grades in the B range. Even in the Urban and Plains zones at Lee Martinez Park and the ELC, for instance, some sub-reaches were graded in the B range. Reach-scale scores range from B- to F+, reflecting the average of several more diverse sub-reaches within each reach.

Fine-scale structure

Fine-scale structure grades are based primarily on streambed characteristics at a scale relevant to aquatic insects and larval fish. The predominant factor is availability of interstitial space within bed material, which may be reduced by bed armoring, embeddedness, fine sediment accumulation, or excessive algae growth which are primarily caused by a decreased frequency of flushing flows (Figure 4.12). Grades were similar to coarse-scale grades because the same types of stressors affect them both. Fine structure sub-reach grades ranged from A- to F- (Tables 4.8 a and b).

Figure 4.12: Fine sediment deposited following fires clogs spaces between the cobbles. This eliminates important habitat for aquatic insects and spawning fish (left). Team member Johannes Beeby reaches down to check the embeddedness of cobble while scoring the fine scale metric.

As with coarse-scale structure indicators, failing grades were assigned to flat sub-reaches just upstream of diversion dams and bridge constrictions that form backwater conditions at high flow. On these segments, the bed is static and armored or embedded with fine sediment or algae. There is little to no available interstitial space. Clean and unarmored sub-reaches exist throughout the study area where the river is unaffected by in-stream structures. The 2013 flood, followed by several years with above-average peak flows, may affect the interpretation of results based on field observations for this metric. Flows during these events appear to have been high enough to mobilize coarser bed material and flush fines from the majority of riffles. These observations confirm that bed mobility and bed flushing functions are still intact, to varying degrees, along most reaches of the Poudre, justifying a range of scores in the B to C range for reaches that are not highly impacted by in-stream structures or dams.

Aquatic Life

Aquatic life indicator scores ranged from B- to C, with roughly one-half of the reaches in the B range (Table 4.11). Surprisingly, three reaches in the Urban and Plains zones received higher grades for aquatic life than three of the Canyon zone reaches; however, the overall aquatic life scores from the Canyon zone were higher than the Urban zone. In the majority of stream reaches, breaks in habitat are caused by cross-channel structures severely impact the aquatic habitat connectivity grades. Habitat segmentation caused by these structures is the main cause for the depression of aquatic life scores in the Canyon zone. The lack of cross-channel structures improved habitat connectivity in the downstream portion of the Urban zone and within the Plains zone. While the ability to support a fishery is a critical

and highly valued aspect of the river, it was important to represent available data accurately without introducing additional uncertainty. Because fish sampling data are infrequent and conditions of the river can be variable, it was decided to not extrapolate fish sampling data between sampling stations for this baseline assessment. Therefore**, information and grades for native fish and trout were included in the SOPR, but they were not factored into the overall indicator score.**

Table 4.11: Summary of aquatic life indicator scores and grades organized by zones and reaches.

Aquatic insects

Aquatic insects can be impacted by a wide range of anthropogenic activities. These organisms are particularly sensitive to changes in water quality and habitat modifications such as increases in fine sediment and algal growth. As the aquatic insect community responds to certain impacts, other aquatic life (such as fish) may also be influenced. To provide an assessment of impacts from stressors, this study considered six sub-metrics, each representing a different aspect of aquatic insect community structure and function. Index scores for the six sub-metrics at the 13 sample stations are shown in Table 4.12, along with the aquatic insect grades for each stream reach. Index scores are measured on a scale of 0 to 100; however, **these values do not do not relate to the academic grading scale**. Index scores are translated into health grades in a separate step.

Stream reaches with high aquatic insect grades generally supported a well-balanced and diverse insect community that included a variety of sensitive taxa. Aquatic insect grades ranged from B+ to C throughout the study area, and most reaches scored in the B range (Table 4.12). The highest grades (A- to B+) were assigned to the Canyon zone (and upstream), and these scores were an indication that the aquatic conditions support a healthy benthic macroinvertebrate community. The lowest scores were produced in reaches 9 and 10 in the Urban zone (78) and reaches 16-18 in the Plains zone (75). Although these scores were somewhat lower than the rest of the study area, results from the six sub-metrics suggest that aquatic conditions support adequate community structure, including some taxa that are considered sensitive to stress. An evaluation of each sub-metric has been included to provide a more thorough evaluation of the macroinvertebrate communities in each sampling reach.

Table 4.12: Index scores (MMI) for the six sub-metrics aquatic insect at the 13 sample stations along with the grades for each reach. A map of these sampling locations is presented in Appendix C).

EP Taxa *(Mayflies and stoneflies)*

The EP Taxa metric measures community richness based on the presence or absence of Ephemeroptera and Plecoptera (mayfly and stonefly, respectively) taxa, two insect orders that are sensitive to a variety of human-induced changes in water quality and habitat (Figure 4.13). All of the sites in the Canyon, Rural, and Urban zones received a score of 100 from this sub-metric suggesting that mayfly and stonefly taxa were well-represented at each sampling station (Table 4.12) A decrease in sensitive taxa was observed in the Plains zone which may have been an indication that impacts were increasing downstream from Prospect Avenue; however, the decrease in EP Taxa scores exhibited at sites PROS and PBOX were relatively minor and a variety of other sensitive taxa continued to exist at these sites in the Plains zone.

Figure 4.13: A common species of stonefly (*Claassenia sabulosa)*, represented one of the sensitive taxa measured with the EP Taxa sub-metric within the Cache la Poudre River.

Percent Chironomidae *(non-biting midges)*

The Percent Chironomidae sub-metric measures the relative abundance of the family Chironomidae (non-biting midges). Chironomidae are typically considered more tolerant to changes in aquatic conditions than other insect taxa, so changes in the proportion of Chironomidae can be a good indicator of stress. The Percent Chironomidae sub-metric is sensitive to a variety of potential stressors including increased nutrients. Scores from this metric were somewhat variable within the study area; however, there appeared to be a slight increase in stress (represented by lower scores) at most sites in the Rural, Urban, and Plains zones. The highest proportion of non-biting midges were found at the farthest downstream site (PBOX) in the Plains zone which produced the lowest Percent Chironomidae score (55). As with the EP Taxa sub-metric, these results suggest that macroinvertebrate communities have been somewhat disturbed in areas of the river near urban areas.

Sensitive Plains Families

The Sensitive Plains Families sub-metric was designed by the CDPHE specifically for Colorado plains streams. It is a general measure of aquatic condition based on the presence or absence of key taxa that are known to occur in lower elevation Colorado streams (Figure 4.14). Results from this sub-metric produced scores ranging from 11 at site PRaLM to 81 at site PLINC – both stations are in the Urban zone. This sub-metric is a CDPHE regulatory requirement; however, it is possibly biased at high elevations since the natural range of many of the indicator taxa does not extend beyond the plains. Because of these limitations, the low scores produced at higher elevation sites may not be indicative of poor aquatic conditions. On the other hand, the lower scores for the Sensitive Plains Families in the Urban and Plains zones probably detect real health impairment caused by land use and management.

Figure 4.14: A mayfly (*Leptophlebia cupida*) that is a representative from one of the Sensitive Plains Families (Leptophlebiidae).

Predator and Shredder taxa

The Predator/Shredder Taxa sub-metric measures the abundance of taxa in the predator and shredder feeding (food acquisition) groups. Both predators and shredders are moderately sensitive to ecological disturbances that alter the availability of food in the stream. Results from this sub-metric provide evidence of high numbers (represented by higher scores) of these sensitive taxa within most of the study area with decreasing scores in the lower reaches of the Urban zone and throughout the Plains zone. Like the other sub-metrics, the decrease in the number of predators and shredders within the Urban and Plains zones provides additional evidence that stress has increased in these downstream reaches.

Clinger Taxa

The Clinger Taxa sub-metric measures the number of insect taxa that cling to clean substrate surfaces in riffle habitat (Figure 4.15). These taxa are often reduced when the natural substrate material becomes embedded or covered by fine sediment or algae. All the sample sites in the study area produced the highest possible score for this sub-metric (100) which showed that clingers are well-represented throughout the entire study area, even in regions that may be susceptible to urban or agricultural runoff.

Figure 4.15: This species of caddisfly (*Brachycentrus americanus*) is an example of a Clinger Taxa.

Percent Non-Insect Taxa

Insects are generally more sensitive to changes in water quality or habitat alterations than non-insects (such as snails, worms, mites, etc.), therefore high proportions of non-insect taxa in benthic communities can be another indicator of stress. Results from this sub-metric showed that the proportions of non-insect taxa were somewhat variable in the study area and the lowest proportions of

these taxa (represented by higher scores) were produced at the two sites within the Rural zone. Despite its location upstream the SOPR study area and above most known sources of stress, site PRbRB produced one of the lowest non-insect taxa scores (44) (Table 4.12). The macroinvertebrate community at this location contained a high proportion of aquatic worms belonging to the family Naididae, a group known to be tolerant to nutrients as well as a variety of other aquatic disturbances. It is possible that the high proportion of worms at this site was a response perturbations occurring upstream near the community of Rustic, Colorado. Elevated numbers of Non-Insect Taxa were also observed at site PLINC; however, scores from this sub-metric improved farther downstream in the Plains zone.

Aquatic habitat connectivity

As described previously, the many cross-channel structures present in the SOPR study area severely fragment the aquatic habitat. The longest section of unobstructed flow is about 11 miles. This reach lies between the Timnath Reservoir Inlet Diversion and Greeley Canal No.3 Diversion. With 16 diversion dams in the study area, the majority of reaches scored a D or lower indicating that most unobstructed reaches are less than two miles long. Reaches within the Rural zone scored lowest, with diversion dams blocking fish passage occurring nearly every mile (see Figure 3.1).

Native fish

At least 20 (and likely more) native fish species historically occupied the Urban and Plains zones of the Poudre River (Colorado Parks and Wildlife, Aquatic Research Station, 2016). The loss of more than half the local species over the past 50 or so years is alarming (Figure 4.16). At least four species have not been captured since the mid- to late-20th century and are thought to be locally extirpated. These are the central stoneroller, common shiner, northern plains killifish, and bigmouth shiner. The orange spotted sunfish, red shiner, and brassy minnow have not been observed on the Poudre upstream of I-25 since 2003, 2005, and 2010, respectively, while the creek chub is becoming increasingly rare.

Figure 4.16: The number of native fish species in the Poudre River has steadily declined over time.

In 2015, ten native fish species were captured across the five sampling stations, including creek chub, fathead minnow, Johnny darter, longnose sucker, longnose dace, plains topminnow, sand shiner, and white sucker (Figure 4.17). The plains topminnow has special status in Colorado, where it is listed as a Tier 1 species of greatest conservation need in CPW's State Wildlife Action Plan (Colorado Parks and Wildlife, 2015). Flathead minnow, longnose sucker, and white sucker were captured at all five stations. Longnose dace and green sunfish were found at four of the five stations, Johnny darter at three, plains topminnow and sand shiner at two, and creek chub at just one.

Figure 4.17: The Johnny darter is a small-bodied plains fish that is still present in the Fort Collins reach of the Poudre.

The native fish metric is based on the number of native species still present in sustainable populations, measured as the number of species and number of life stages captured in samples. The number of species, life stages, and corresponding metric grades are shown in Table 4.13. Five reaches were sampled in the Plains and Urban zones, and the number of species present ranged from four to eight, with multiple life stages represented for only about half the species at each site. Consequently, grades ranged from C to F.

Table 4.13: Native fish indicator scores in five reaches of the Poudre River.

Zone	Canyon			Rural			Urban							Plains				
Reach	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
Sample Station										P1			C1	P2		P3		P4
Number of Species										6			8	4		6		7
Life Stages										half			half	half		half		half
Native Fish										65			75	55		65		70

The disappearance of native fish parallels fundamental changes in the river system and is, therefore, a powerful indicator of the degree of biological impairment. The most likely stressors contributing to this negative trend in species diversity are de-watering (impaired base flow regime), habitat fragmentation from man-made barriers to fish migration (*i.e.,* aquatic habitat connectivity impairment), decreased habitat complexity (*i.e.,* physical structure impairment), altered temperature regime (*i.e.,* water quality impairment), and competition with non-native species. Even temporary degradation of habitat conditions can have permanent or long-term effects on native fish because when a reach becomes uninhabitable, even for a short time, it is often improbable or impossible for them to return owing to the numerous fish migration barriers.

Native fish diversity tends to be correlated with local habitat complexity; however, there is a larger landscape-scale trend of extirpation. Fish species are disappearing from the river altogether as their longitudinal range shrinks. The red shiner and bigmouth shiner were previously detected in the Plains zone, but are now found only east of I-25. In addition to the species already extirpated from the study area, the plains topminnow's range appears to be contracting upstream since it was found only at the two most upstream sampling stations. The sand shiner was found only at the two downstream stations, and its range appears to be contracting downstream.

Trout

Brown trout are not native to the Poudre River, but the species has become dominant on most Colorado Front Range rivers including the Poudre. It is a valued game fish and also a common biological indicator of aquatic habitat conditions. Trout populations were sampled at two stations in the study area in 2015, and data were used to grade the trout metric for the two reaches represented (Figure 4.18).

The uppermost reach of the Canyon zone, between Munroe Diversion and the North Fork was graded B for brown trout. Multiple-age classes and a high-biomass estimate indicate a naturally-sustaining population with high biomass. While there are high densities of brown trout, a large proportion of them are below quality-size (*i.e.,* less than nine inches), in the six - nine inch range and with a below-average relative weight. These characteristics brought down the overall reach score. Population estimate data suggests 436 brown trout per mile greater that are quality-size or greater. This is considered a moderate or mediocre recreational fishery.

Figure 4.18: Brown trout thrives in much of the study area (photograph courtesy of Colorado Parks and Wildlife).

The reach between Shields Street and College Avenue in the Urban zone was graded A, due to age class diversity as well as high biomass and population estimates. Multiple age classes, high recruitment level, and high numbers of adult fish indicate a well-supported and natural- sustaining trout population. Population estimates suggest 625 quality-size fish per mile and biomass; this exceeds "gold medal" standards for trout, indicating a viable recreational fishery and good support of faunal food webs (Figure 4.19). Results for the six sub-metrics are detailed in Table 4.14.

Table 4.14: Trout indicator scores in two reaches of the Poudre River.

Zone	Canyon	Urban
Reach	**1. Munroe to North Fork**	**9. Shields to College**
Sample Station	Gateway Park	Lee Martinez Park
Age classes	> 4 age classes	> 4 age classes
Recruitment	Low (600 age-0 trout/mile)	High (1100 age-0 trout/mile)
Recreation potential	Moderate (360 quality trout/mile)	High (590 quality trout/mile)
Relative weight	Below average (0.86)	Average (0.94)
Biomass	69 lb/acre	73 lb/acre
Population number	High 1430 stock size trout/mile	High 792 stock size trout/mile
Trout Metric	**85**	**95**

Trout populations are sensitive to a suite of stressors. Common factors limiting trout populations on the Poudre include poor coarse physical habitat diversity, water quality (especially temperature regime and dissolved oxygen), critically low flows during summer and winter, seasonal dry-ups, and migration barriers. Healthy, naturally-sustaining trout populations (at least for the short term) indicate that none of these factors are currently critical on the two reaches that were sampled. The exceptional trout population in the Urban zone in 2015 is partially due to several years in a row of higher-than average flow. A self-sustaining population of trout on this historically warm-water reach, combined with the evidence of declining native warm-water fish species, suggests that the current water temperature regime is cooler than it was historically, but it is difficult to tease apart all the factors affecting temperature and fish populations.

Figure 4.19: Osprey live and hunt along the Poudre River and rely on fish and a central food source.

5 River health scores and key issues by zone

5.1 Overview of Poudre River health

Land-use changes in the Poudre River corridor have been pervasive since European settlement in the middle 1800's. The once-broad and complex river-riparian corridor on the plains has been dramatically narrowed and simplified. We will never know exactly what the Poudre looked like before these lands were settled (Figure 5.1). Even by the time the town of Fort Collins was established around 1870, more than a decade of farming and ranching had occurred in the area, and nearly 30 years before that, the fur trade had essentially extirpated beavers from the region. Today, no part of the river system remains untouched. The river is channelized, confined, and armored for much of its length, and flows are heavily managed to meet water-use needs. Much of the historic riparian zone and floodplain has been developed or converted to other land uses.

Figure 5.1: *On the Cache la Poudre River*, painted by Worthington Whittredge in 1876, is the earliest depiction of the Poudre River on the plains that we have. Farming and ranching land uses had already been established for decades by this time, and the river and riparian zone appear to be already impacted through clearing of the understory. Conversely the canopy was sparser historically, as this painting depicts the river before exotic trees such as crack willow invaded and crowed the canopy.

And yet, all things considered, the Poudre is still a relatively healthy and resilient river. Overall, this assessment gives it a C rating, meaning that it is functionally healthy. The river still supports the basic

natural river and riparian functions—even through the Urban zone—despite a suite of ecological stressors that affect all aspects of river health.

The SOPR is a baseline against which the City can measure progress towards its vision of "…*sustaining a healthy and resilient Cache la Poudre River"*. The health assessment scores (Section 4) reveal the ramifications that stressors (described in Section 3) have on ecosystem condition and the degree of impairment observed in each zone and reach. Here in Section 5, the focus shifts to an overview of river health, describing the link between stressors and impairment for each of the four zones. Poudre River health indicator grades for each zone are compared to the ranges recommended by river experts and resource managers—as described in the Poudre RHAF—to highlight best and the most impaired aspects of river health. This section also includes an analysis of the causes of impairment and reveals which problems may be practically solved.

Patterns of land and water use vary across the four zones, but the most influential stressors are consistent throughout the study area. To provide a succinct summary of key issues that affect modern-day river health, Table 5.1 provides a matrix illustrating the relative contribution of each stressor on each indicator. The City has influence over some of these stressors—and therefore an opportunity to improve river conditions—and less or no influence over others. This section describes the general approaches the City could take towards improving river health based on a summary of conditions for each of the four zones. This report, however, does not make recommendations for specific projects or actions to manage factors that contribute to river health, as these decisions must involve the broader set of stakeholders.

For this chapter, the summaries of river health by zone are organized generally by indicators or groups of indicators that are related (for example, floodplain extent and the riparian condition indicators can be discussed together.

Table 5.1: Matrix that relates the causes of impairment (stressors) on the vertical axis with the degree of impairment (indicator scores) on the horizontal axis. The degree of impairment is based on a high, medium, and low scale (dark grey to light grey, respectively).

Poudre River Stressor Matrix										
Stressors	Flow Regime	Sediment Regime	Water Quality	Floodplain Connectivity	Riparian Condition	River Form	Resilience	Physical Structure	Aquatic Life	River Health
Diversions (withdrawals)										
Transbasin diversions (augmentation)										
Large dams/reservoirs

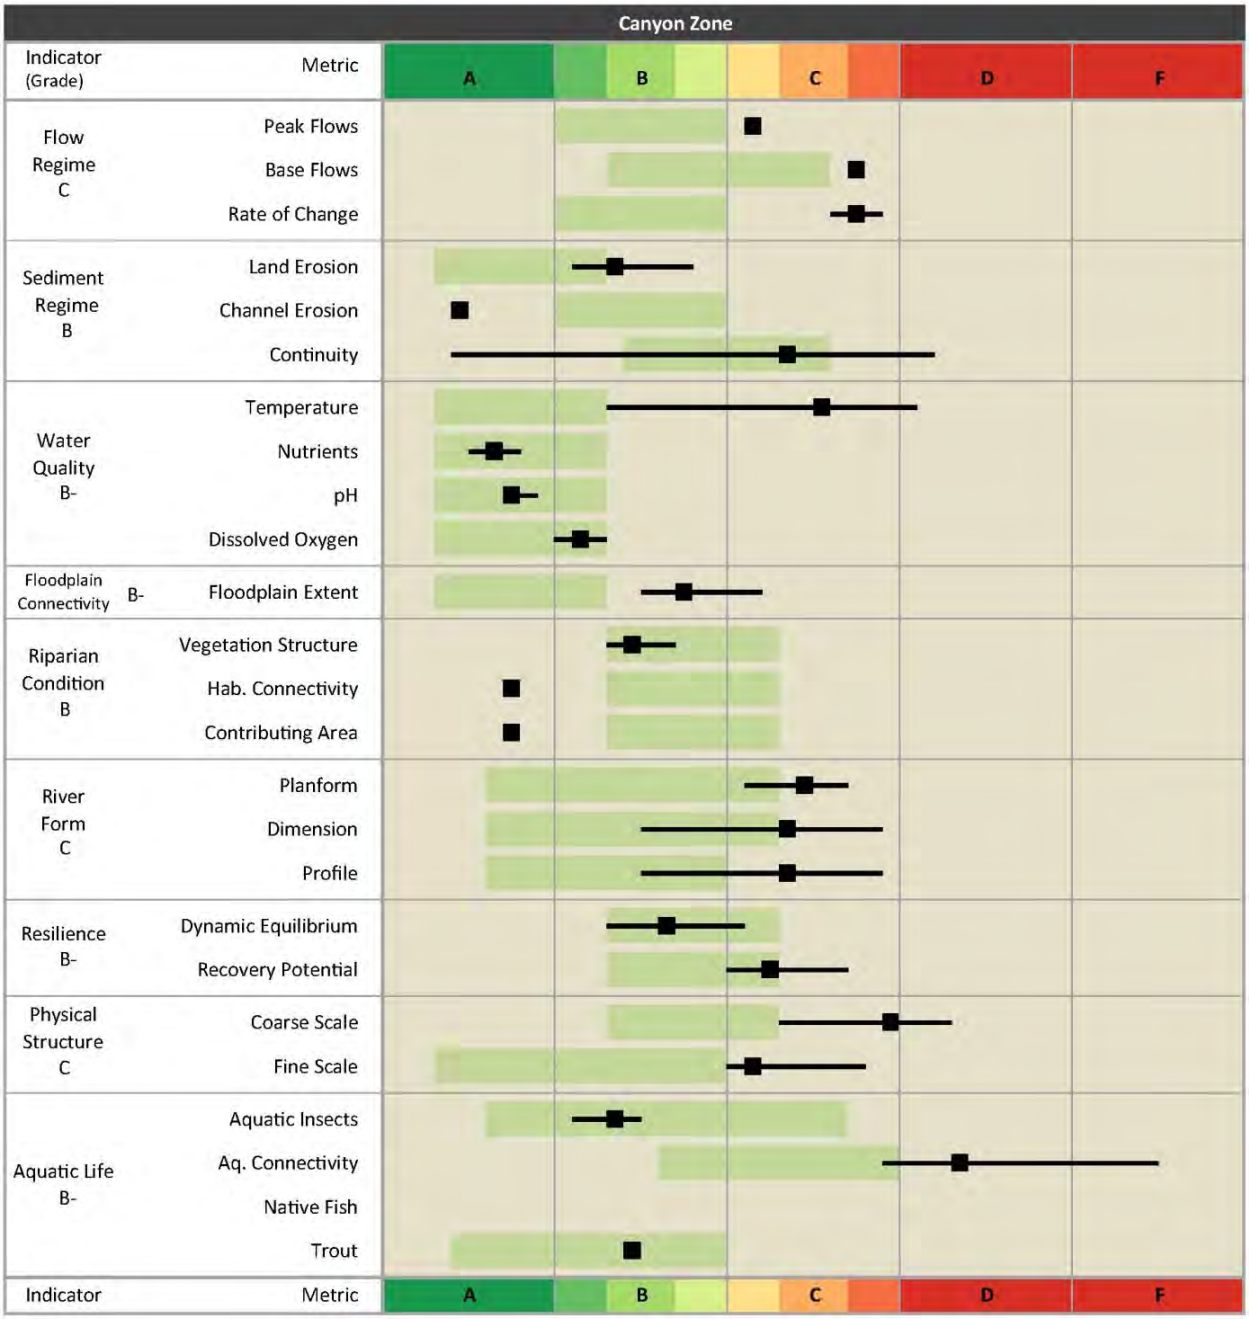
5.2 Canyon zone

Figure 5.2: In the Canyon zone, the river is bounded by a narrow floodplain and confined between steep canyon walls, rocky hills and/or the CO Highway 14.

Geology governs the character of the Canyon zone. Relatively steep and straight, the river is bounded by a narrow floodplain and riparian corridor that is confined between steep canyon walls and rocky hills (Figure 5.2). The influence of peak flows on the floodplain is therefore limited, and naturally-resistant rock banks are insensitive to the rushing waters. A narrow band of riparian vegetation provides wildlife habitat and a critical migration corridor. The forested watershed is mostly undeveloped, and to a large extent, its natural hydrologic, geomorphic, and biogeochemical processes are intact, providing support for river health (Table 5.2).

Table 5.2: Metric grades in relation to recommended ranges for the Canyon zone. Recommended ranges (green bars) represent expert opinion for reasonable and practical potential metric grades given existing land and water-use constraints. Points (square black boxes) present the average grade for the given metric for this zone. The black lines show the range of results across the reaches within this zone.



Flow regime scores are below recommended ranges for all three metrics on the Canyon zone, suggesting some room for improvement in peak flow, base flow, and rate of change, albeit the concerns are less than the downstream zones. Cumulative impacts from within the watershed and various dams are responsible for some of the alterations to flow regime, but flows are most directly impacted by

diversions that occur within this zone. The scores for all three metrics are closely linked to the magnitude and timing of diversions, storage, and releases.

The overwhelming sediment regime stressors are the large dams that interrupt sediment continuity, so scores for the continuity metric fall below the recommended range downstream of the North Fork confluence. The land-erosion metric scored slightly below the recommended range due to the impacts from recent fires, and this score will improve as the burn scars revegetate. In addition, the Coalition for the Poudre River Watershed and several stakeholder groups, including the City of Fort Collins Utilities, have developed an Upper Poudre Resilience Watershed Plan. The purpose of the plan is to improve watershed resilience through watershed restoration activities aimed to reduce risk of future wildfires and post-fire erosion (Figure 5.3).

Figure 5.3: Post-fire land erosion causing a major debris flow into the Poudre near the upper Landing Campground.

The channel erosion metric for the sediment indicator was above the recommended range. In the Canyon zone channel erosion is altered by riprap banks along Highway 14. However, sediment supply from bank erosion would naturally be limited in this confined canyon setting.

Water quality

Nutrient, pH, and dissolved oxygen scores in the Canyon zone fell within recommended ranges. Water temperature is within range upstream of the North Fork confluence, but fell to D+ immediately downstream due to seasonal regulatory standards exceedances. The D+ grade may overestimate the degree of temperature impairment, however, since exceedances are rare and limited to shoulder seasons (see Section 4, water quality subsection). The City's monitoring data do confirm that temperatures on the North Fork are generally warmer than the mainstem between April and November, however. This may be because the North Fork basin is a naturally warmer habitat, or it could be an effect of Seaman Reservoir. The direct influence of Seaman Reservoir on water temperatures is not straightforward. A review of temperature data collected through the City of Fort Collins cooperative monitoring program shows that the reservoir can have both warming or cooling effects on the North Fork, most likely depending on the timing, volume, and nature of reservoir releases. Whether releases are made from the spillway or bottom outlet is of particular importance. The somewhat warmer temperatures downstream of the confluence likely result from combination of natural and anthropogenic factors.

River channel *(river form, resilience and physical structure indicators)*

Most of the physical geomorphic metric scores in the Canyon zone are below recommended ranges, suggesting the potential for improvement, but this may be misleading since early estimates for these metrics in the original RHAF underestimated the degree of impairment to floodplain connectivity, river form, resilience, and physical structure. The original estimates of current condition presented in the RHAF for these metrics are in the A to B range, but measured results are from B- to C. Localized impacts at diversion dams and bridges account for some of the physical river channel impairment, but the primary cause is Highway 14, which runs up the narrow canyon parallel to the river. Portions of the road are built on fill that encroaches on the already-limited floodplain area. Areas where road fill impinges on the river are physically stabilized using bank armor, which itself is a source of impairment to physical structure. Armored reaches have proven resistant to damage from floods, but considerable damage would occur and there would be limited potential for unassisted recovery if or when these banks do fail.

Riparian corridor *(floodplain connectivity and riparian condition indicators)*

The Canyon zone was graded B for riparian condition and floodplain connectivity, reflecting the highly functioning nature of the streamside habitat. All of the riparian condition metrics were at or above recommended ranges. The recommended range for floodplain connectivity from A to B+ is greater than the observed grades (B to C+) indicating that the effects of Highway 14 encroachment and diversion dams are greater than previously estimated. Highway 14 is the sole source of impairment to riparian zone health on most of the canyon reaches, and scores generally correlate with the degree to which the highway encroaches on the floodplain and riparian zone. Outside of the influence of the road, such as on the opposite bank of the river, riparian zone habitat is essentially in natural condition. Most of the reach is managed for natural habitat and other than the highway, there are few artificial barriers to the movement of organisms through and between riparian habitats. As with habitat connectivity, the

contributing area surrounding the Canyon zone is in very good condition and managed primarily as wildland by federal, state, city, and county agencies.

Aquatic life

The aquatic insect indicator results provide strong evidence of healthy and functional aquatic fauna communities in the Canyon zone. While grades ranged from B to B+, individual metric values were well within the recommended ranges, and scores for all three sampling sites were among the highest within the study area. High scores for the EP taxa and clinger taxa sub-metrics show that the zone supports insect taxa that are considered sensitive to a variety of perturbations. The only evidence of minor stress in this zone was provided by the percent of non-biting midges (Chironomidae) and non-insect taxa that known to be more tolerant of poor water quality. The zone also supports a relatively healthy trout population and a viable trout fishery, at least on the sampled reach above the North Fork. However, aquatic habitat connectivity is severely limited in the zone due to the frequency of major structural barriers with metric grades from C- to F. The recommended range for this metric (B to C-) would be realistic only if instream barriers could be removed or reconfigured.

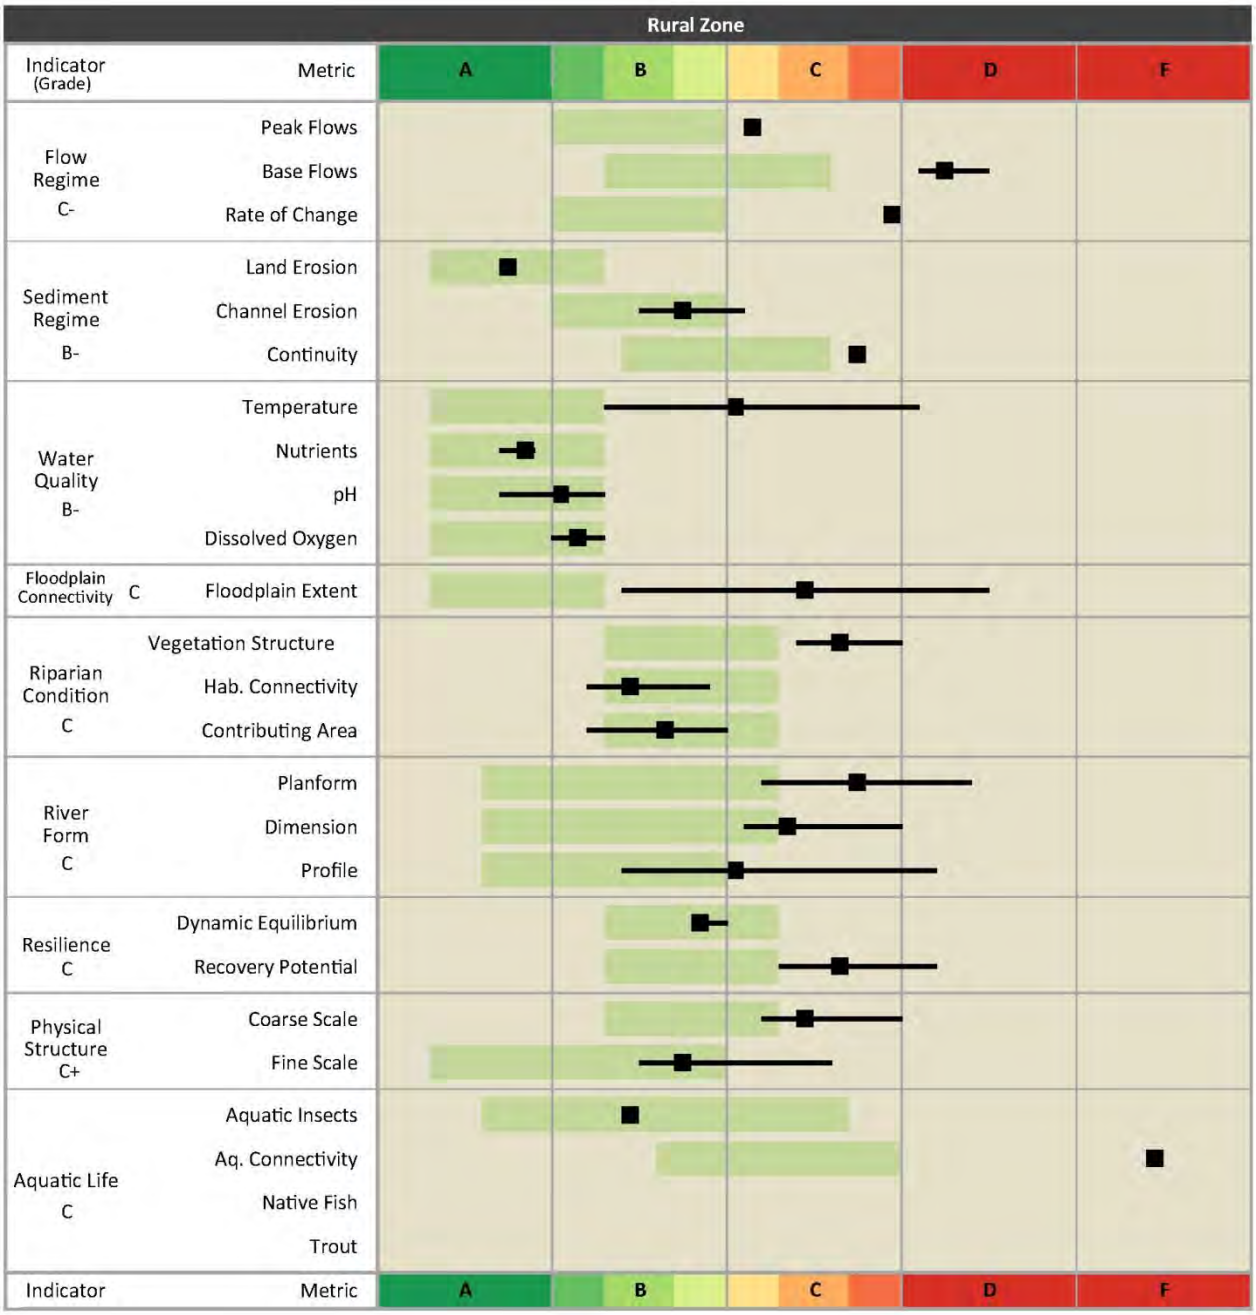
Figure 5.3: In the Canyon zone the confluence of the North Fork (the largest tributary in the canyon) into the main stem at Gateway Natural Area influences water quality parameters and therrefor habitat foraquatic wildlife.

5.3 Rural zone

Figure 5.4: As the river exits the canyon, the gradient begins to slacken, and the native river type shifts to a meandering channel that maintains form and structure through dynamic equilibrium between erosion and sediment supply.

The Poudre transitions from a confined to an unconfined river in the Rural zone, which is a fundamental shift in geomorphic river type (Figure 5.4). In the unconfined reaches downstream of the canyon, the floodplain and riparian zones become critical drivers of river health. Lacking resistant geology, a functional floodplain would be able to dissipate flood waters and their potentially destructive energies. Riparian vegetation provides roughness, which slows flows while lending structural integrity to river banks, serving as important wildlife habitat, and acting as the source of organic material that forms the base of the aquatic food chain. The gradient begins to slacken in this zone, and the native river type shifts to a meandering channel that maintains form and structure through dynamic equilibrium between erosion and sediment supply Figure 5.4). The Rural zone is still classified as cold-water river, with water temperature standards based on the requirements for supporting trout. The Rural zone is where land use shifts from wildland to rural development, and agriculture, eventually phasing into urban development (Table 5.3).

Table 5.3: Metric grades in relation to recommended ranges for the Rural zone. Recommended ranges (green bars) represent expert opinion for reasonable and practical potential metric grades given existing land and water-use constraints. Points (square black boxes) present the average grade for the given metric for this zone. The black lines show the range of results across the reaches within this zone.



Flow and sediment

All the flow regime metrics scored well below recommended ranges in the Rural zone, with diversions being the greatest cause of impairment. The effects of large reservoirs on reduced peak flows may still be a factor on these reaches, but the direct effects of water management have the greatest influence on flow regime scores. The base flow and rate of change metrics are much more impaired than peak flows. Recommended ranges for these metrics of B to C and B+ to B-, respectively, may not be obtainable unless there is willing collaboration and agreements can be made to manage water diversions differently. The cumulative effect of numerous diversions reduce, peak flows with in this zone. Similarly, base flows are also effected with the Greeley Filter Plant, Little Cache, and Watson Lake diversions all known to cause winter dry-ups. Some flow augmentation at the Hansen Supply Canal can partially offset the withdrawals but the acute impacts to base flow and rate of change are dependent on the timing of these diversions and releases.

The sediment regime indictor scored a B- in the Rural zone. Land erosion grades fell within the recommended range as impacts from the wildfires diminish moving downstream. The channel erosion metric dropped below the recommend range to a C+ below Rist Canyon Road. Bank armoring within this reach is limiting natural bank erosion processes which contribute to sediment supply imbalance. This altered sediment supply can also create accelerated bank erosion in areas without riprap due to the river's increased capacity to transport sediment. Sediment continuity grades fell below the recommended range in this zone reflecting the lingering impacts from the dams in the contributing watershed and, to a lesser degree, the smaller in-line dams within the zone.

Water quality

Water quality in the Rural zone is similar to that of the Canyon zone, with nutrient, pH, and dissolved oxygen grades within recommended ranges and temperature falling short. The reaches that score low for temperature are in the upper portion of the zone, and the degree and causes of impairment are similar to the reaches in the Canyon zone. Temperature grades increase rapidly through the zone. The sudden improvement is due to the fact that the lower reaches in this zone do not exceed temperature standards. This may be due, in part, to the introduction of cold water effluent from Horsetooth Reservoir via the Hansen Supply Canal. While these inflows may offset some of the warming observed in the Canyon zone downstream of the North Fork, the cooler stream temperatures may affect assemblages of fish and other aquatic organisms, both locally and downstream. However there are no fish data for the study period (2015/2016) in this zone and the relatively high aquatic insect scores reflect thresholds set for cooler waters.

River channel *(river form, resilience and physical structure indicators)*

Channelization, berms, armor, diversion dam structures, and bridges have a strong negative influence on floodplain connectivity, river form, resilience, and physical structure through the Rural zone. The effects of these stressors are very localized, but they are so widespread that most of the river channel indicators show impairment through the zone. A few segments, however, display a more natural form

and variation where the river has not been contained or confined. In these segments, natural floodplains still exist and the river is not as constrained or entrenched, though nowhere are they wide enough to meet the target range for the metric. Consequently, the river has been able to adjust its form to changing sediment and flow regimes and maintain a more natural form that is appropriate for the landscape position. As a result, net dynamic equilibrium scores are within the recommended range. The recovery potential metric scored well below the recommended range, however. Dams, bridges, berms, armored banks, and other confining structures on the reach increase the risk of damage and severely limit the river's ability to recover from large to moderate flood events.

Coarse-scale structure, such as overhanging banks and a mosaic of complex aquatic habitat, has suffered in the Rural zone with the installation of bank armoring and other active channel modifications. Even though some of the better pool-riffle sequencing was found in this zone, it is still lacking in pool habitat and structural diversity. The Rural zone scored best for fine-scale physical structure because of the recent occurrence of flushing flows on bed mobility, and most of the reaches are within the target range for this metric.

Riparian corridor *(floodplain connectivity and riparian condition indicators)*

Floodplain extent is well below the range recommended for river health in the Rural zone, and this is mostly the result of channelization, berms, and other direct physical impacts. Low-impact land uses dominate the historical floodplain area and SOPR riparian zone (defined as the corridor 100m from either bank). Today's riparian zone is largely functional owing to the lack of widespread or intensive development and relatively low presence of problematic woody species. Overall, riparian condition in the Rural zone rated a C. This grade accurately reflects the functional ability of the riparian habitats to support river health, and, in turn, the ability of the rural landscape to support somewhat healthy riparian habitat, while acknowledging that land use and land cover changes have substantially altered the form, structure, functioning and ecological integrity of the riparian habitats. The vegetation structure and complexity metric was the only riparian metric below the recommended range. The lower-than-desirable grade stems from the fact that much of the riparian zone vegetation has been cleared for agriculture or is no longer hydrologically connected to the river. Two large gravel ponds also severely impair riparian condition on one of the reaches. Sections of roadway affect small portions of the riparian zone, and in the town of Laporte, residential development and Cache la Poudre schools intrude into the riparian zone. The Watson Lake Fish Hatchery is another significant development limiting the riparian zone function.

The habitat connectivity scores are generally good throughout the Rural zone. Each reach had some disruption in the continuity of riparian habitat, such as intrusion of roads, or urban development. The most widespread impact on habitat connectivity is forest clearing for agriculture. Cleared areas still allow passage of most organisms, but cleared habitats are more difficult or dangerous for many organisms to cross, exposing them to an increased risk of predation or heat stress, for example. The contributing area metric indicates that the land use beyond the riparian zone is generally supportive of river health. Widespread light agriculture and small areas of intensive agriculture impair some of the

ability of these areas to support river health, but nevertheless most of the contributing area is vegetated and only sparsely developed.

Aquatic life

Aquatic insect grades indicate that the level of stress to aquatic life may have increased slightly in the Rural zone based on minor shifts in the aquatic insect community compared to the Canyon zone. The zone received a C grade which is slightly lower than the grade in the Canyon zone. The EP and clinger taxa sub-metrics reflect healthy aquatic conditions through the zone, however. The number of sensitive taxa remained high in the Rural zone, while the proportion of some aquatic organisms that are considered tolerant to anthropogenic stressors increased slightly. These findings are likely in part the result of increases in agriculture in the surrounding area.

The Rural zone was not directly sampled for fish populations in 2015 so no grades are presented for this zone; however, it has been frequently sampled in the past. Despite the presence of localized habitat features that can influence trout populations within short sections of river, the overall population can be estimated based on prior sampling, as well as upstream and downstream sample points. These extrapolations suggest that in general the Rural zone supports a thriving trout fishery.

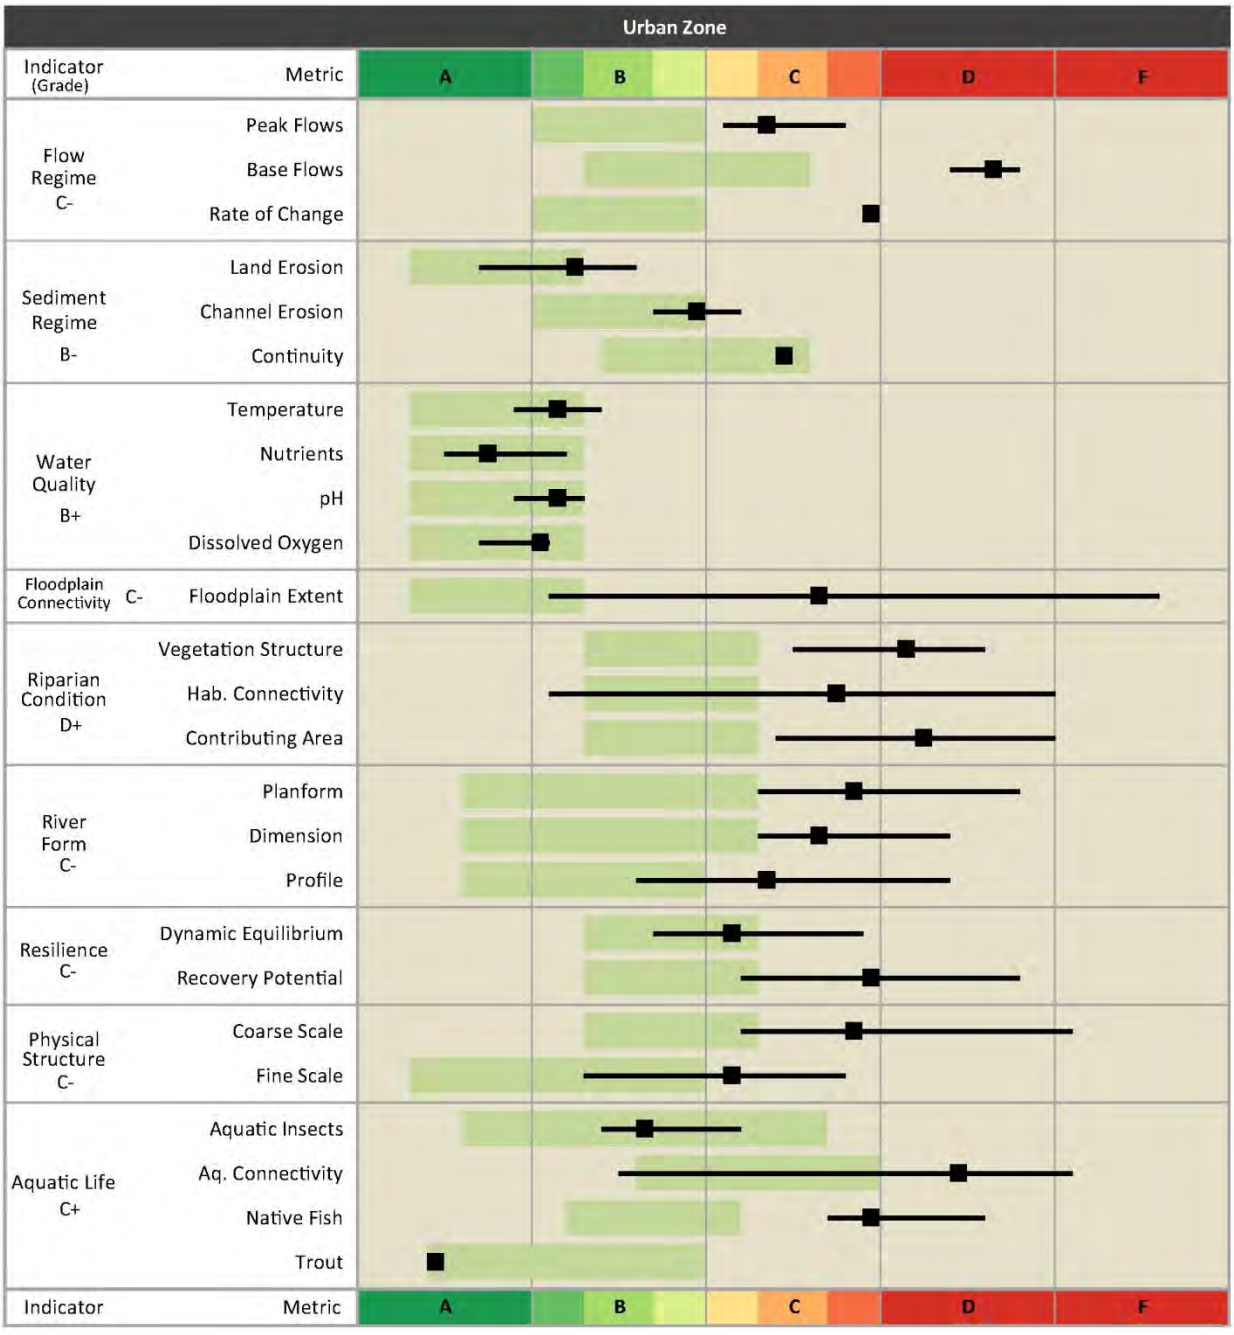
Figure 5.5: In contrast to the foot-long brown trout, the small-bodied longnose dace is one of the few native plains fish that can also survive in slightly cooler waters. It lives in the Poudre all the way up to Gateway.

5.4 Urban zone

As the river courses into and through town, its gradient slackens further and the Poudre begins its transition towards becoming a warm-water river (Figure 5.6). In this zone, the river's natural form would have been multiple channels interwoven into a braided pattern, running through an expansive and unconfined floodplain. Riparian vegetation would have formed a complex mosaic of habitats, providing critical support to river functions and health. Floods and disturbance were historically common and would have shaped most ecosystem processes (Table 5.4).

Figure 5.6: The river takes a narrow course through the heart of the Urban zone where the Linden Street crosses the River.

Table 5.4: Metric grades in relation to recommended ranges for the Urban zone. Recommended ranges (green bars) represent expert opinion for reasonable and practical potential metric grades given existing land and water-use constraints. Points (square black boxes) present the average grade for the given metric for this zone. The black lines show the range of results across the reaches within this zone.



Flow and sediment

The pattern of flow regime impairment in the Urban zone is similar to the Rural zone, but alterations are more pronounced because the diversions and flow reductions are cumulative. Peak flow, base flow, and rate of change metrics are all below the recommended ranges.

The sediment regime score dropped slightly in the Urban zone, but remained at a B- grade. Sediment grades generally decreased moving downstream through the Urban zone as land uses increasingly impact the sediment regime. Land erosion scored an A in the upper reaches of the Urban zone, but fell below the recommended range to a B+ at Shields Street due to increased urbanization and development surrounding the river. Channel erosion scored on the low end of the recommended range in the upper reaches as the river flows through several City owned Natural Areas, but fell below the recommended range to a C+ at College Avenue.

From College Avenue downstream the river becomes heavily impacted by bank armoring and channelization further disrupting natural erosion and deposition processes causing a sediment imbalance.

Figure 5.7: In addition to its construction site sediment and erosion control program, the City's LID Program requires on-site infiltration of stormwater to help prevent in-stream impacts associated with increased imperviousness.

Water quality

Water quality in the Urban zone is quite high, reflecting the quality of water that comes into town from upstream zones, and the City's commitment to protecting water quality in the Poudre River by managing stormwater runoff and meeting regulatory requirements for wastewater effluent. All water quality metrics scored within recommended ranges. Temperature regime grades are high (A- to B+) indicating no excessively warm periods, but the success of coldwater fish and the demise of native warmwater species on this historically warm-water segment may suggest an unnaturally-cold temperature regime—probably due to the release of cold water from Horsetooth Reservoir into the river just upstream at the Hansen Supply Canal.

River channel *(river form, resilience and physical structure indicators)*

The geomorphic (*i.e.,* physical) condition of the Poudre is most compromised in the Urban zone. The majority of the floodplain has been severely encroached upon or cut off by channelization and berms. More than two thirds of the river in this zone is armored and more than half of it is directly affected by eight dams and twelve bridges. These features have severely impacted river form. In most places, the channel is moderately to severely entrenched. Resilience of the system is low in the Urban zone, particularly with regards to natural recovery potential, due to the level of floodplain encroachment and

the number of structures. These alterations increase the risk of flood damage, as well. Channel stability depends almost entirely on artificial stabilization. A few areas remain where a wide buffer of undeveloped land has been maintained along the river corridor especially between Shields Street and College Avenue. Most of the undeveloped riparian zone is managed by Fort Collins Natural Areas or the Parks Department (in the case of Lee Martinez Park).

Bed mobilization and flushing functions appear to be intact in portions of the Urban zone that are not affected by dams or bridge constrictions, but these functional segments are short because there are so many such structures along the river in this zone. There is little physical habitat diversity here, and fewer pools except for notably higher scores in reaches 8 and 9 (from Larimer and Weld diversion to College Avenue) where some segments of river adjusted and became more complex during the 2013 flood (*e.g.*, adding large woody material that helped to create pool habitat). Elsewhere, the river is mostly channelized, and large woody material is limited and actively removed from the channel.

Large woody material has many roles in the riverine ecosystem; for example, it is a critical catalyst of habitat structure formation and an important driver of channel form. The systematic removal of large woody material in this zone limits the ability of the river to provide complex habitat and cover for fish, yet this action is deemed essential to public safety and protection of infrastructure. The need for removal of large woody material is an important challenge in the context of urban river management. Increased awareness of the importance of large woody material in river function and health could help instigate creative solutions to its use in future management plans.

Riparian corridor *(floodplain connectivity and riparian condition indicators)*

Overall, riparian condition in the Urban zone scored a D+. While lower than optimal, there is still some positive health support provided by the remaining habitat, such as flood flow abatement, bank stabilization and overall support of resiliency. Starting at Overland Trail the river undergoes a transformation as it meanders through town. In the uppermost reach—from Overland Trail Road to the Larimer-Weld Diversion—ponds from gravel mining, and associated berms, press almost to the banks of the river in spots. The riparian zone on averaged rated a D in the upper reach. The density of gravel ponds gradually decreases going downstream from the Larimer-Weld Diversion. Further downstream, an increasing amount of the riparian zone is City of Fort Collins property managed by the Natural Areas program. Several former gravel pond sites have been restored as wetland and reconnected to the river, allowing the wetland to directly support river health. Downstream of Shields Street, much of the riparian zone is managed by Natural Areas, and much of the zone remains forested, despite the otherwise urban surroundings. Therefore, in the Urban zone, patches of riparian forest in relatively good health and rated grades as high as B or B+, but too little remains across the zone for it to support the functionality recommended to maintain river health.

The reach below College Avenue is the heart of the river's urban course, and width of the riparian vegetation reduces down to a narrow stream-side band. Commercial and industrial areas encroach on the northern riparian zone, but fortunately, much of the riparian zone of this reach is managed by

Natural Areas. Because of that, despite its highly-urban setting, the riparian zone still remains functional. The newly completed Woodward-Governor site on the east bank of the river includes some habitat restoration. At the time of this survey, vegetation development at this site was rudimentary because of its newness, but as the site develops riparian health is expected to substantially increase.

Within the Urban zone, habitat connectivity varies widely according to the diversity of land uses through which the river flows. At the upper end of the zone, habitat connectivity was severely restricted by past and present gravel mining and the loss of vegetated habitat. Habitat connectivity improves downstream of Taft Hill Road, but in the central urban reaches (reaches 10 and 11), habitat connectivity becomes greatly impaired. Fortunately, there is almost always some vegetation or habitat, at least along the banks, providing limited cover for wildlife passage. From Mulberry Street to the end of the Urban zone, habitat connectivity once again improves as more and more of the riparian zone falls under City ownership and Natural Areas management (Figure 5.8). Much of the contributing area of this zone is urbanized or used for gravel mining and water storage. Only in the middle reaches from Taft Hill Road to College Avenue was the contributing area functional in supporting river health. Elsewhere, most land use in the area assess for the contributing area metric have negative effects on river health. Even so the influences are not as negative as might be expected in an area as developed as the City of Fort Collins.

Figure 5.8 At the lower end to the Urban zone the river is bordered on its northern side by industrial development along Mulberry Avenue, while on its south side the floodplain begins to open up as the land is owned by the City's Natural Areas Department.

Aquatic life

The overall health of aquatic insect communities in the Urban zone appeared to be similar to the Rural zone; although, some of the submetrics detected clear changes in community structure. The SOPR assessment assigned a C grade for aquatic life in the Urban zone. Sub-metrics varied in their ability to detect stress in this stream segment, but the richness of sensitive and specialized insect taxa (demonstrated by the EP Taxa and Clinger Taxa sub-metrics) remained high in the Urban zone even though there stressors were generally more severe as a result of increased anthropogenic activities.

Although the number of sensitive taxa remained elevated, the insects that have developed specialized feeding methods (Predators and Shredders) decreased in a downstream direction. Similarly,

proportions of aquatic organisms that are tolerant to stress *(i.e.,* Chironomidae and Non-Insect Taxa) were higher in the Urban zone compared to the Canyon and Rural zones. These changes in macroinvertebrate community structure were likely caused by increases in anthropogenic stress that come with urbanization.

The high grade (A) for the trout metric at Lee Martinez Park, is confirmation of quality habitat, at least locally (Figure 5.9). Multiple age classes, high recruitment level, and high numbers of adult fish indicate a well-supported and naturally-sustaining trout population. Population estimates suggesting 625 quality-size fish per mile and biomass that exceeds Gold Medal standards indicate a quality recreational fishery. These promising data, however, only represent 2015 and data from other years were not as high.

While good for trout, the river's condition in this zone is not good for native fish, most of which have recently been extirpated from the downstream portion of the zone. In the upstream portion of the zone, the available historic fish sampling data suggest that native warm water fish species richness was naturally limited, presumably because of the colder water. Native fish populations rebound some in the downstream reaches of the zone.

As found throughout the SOPR study area, aquatic habitat connectivity is highly fragmented and detrimental to fishery support. Several large diversion dams pose barriers that prevent native fish from migrating to the Urban zone from the plains, therefore, when populations do crash opportunities for recolonization from downstream are limited. Unlike fish, aquatic insects are less sensitive to in-channel barriers and grades fall within the recommended range. An equally concerning factor affecting native fish in the Urban zone is poor floodplain connectivity. Many of these small bodied native fish species require access to the floodplain as refuge from high flow events, and several species require access to the floodplain for reproduction.

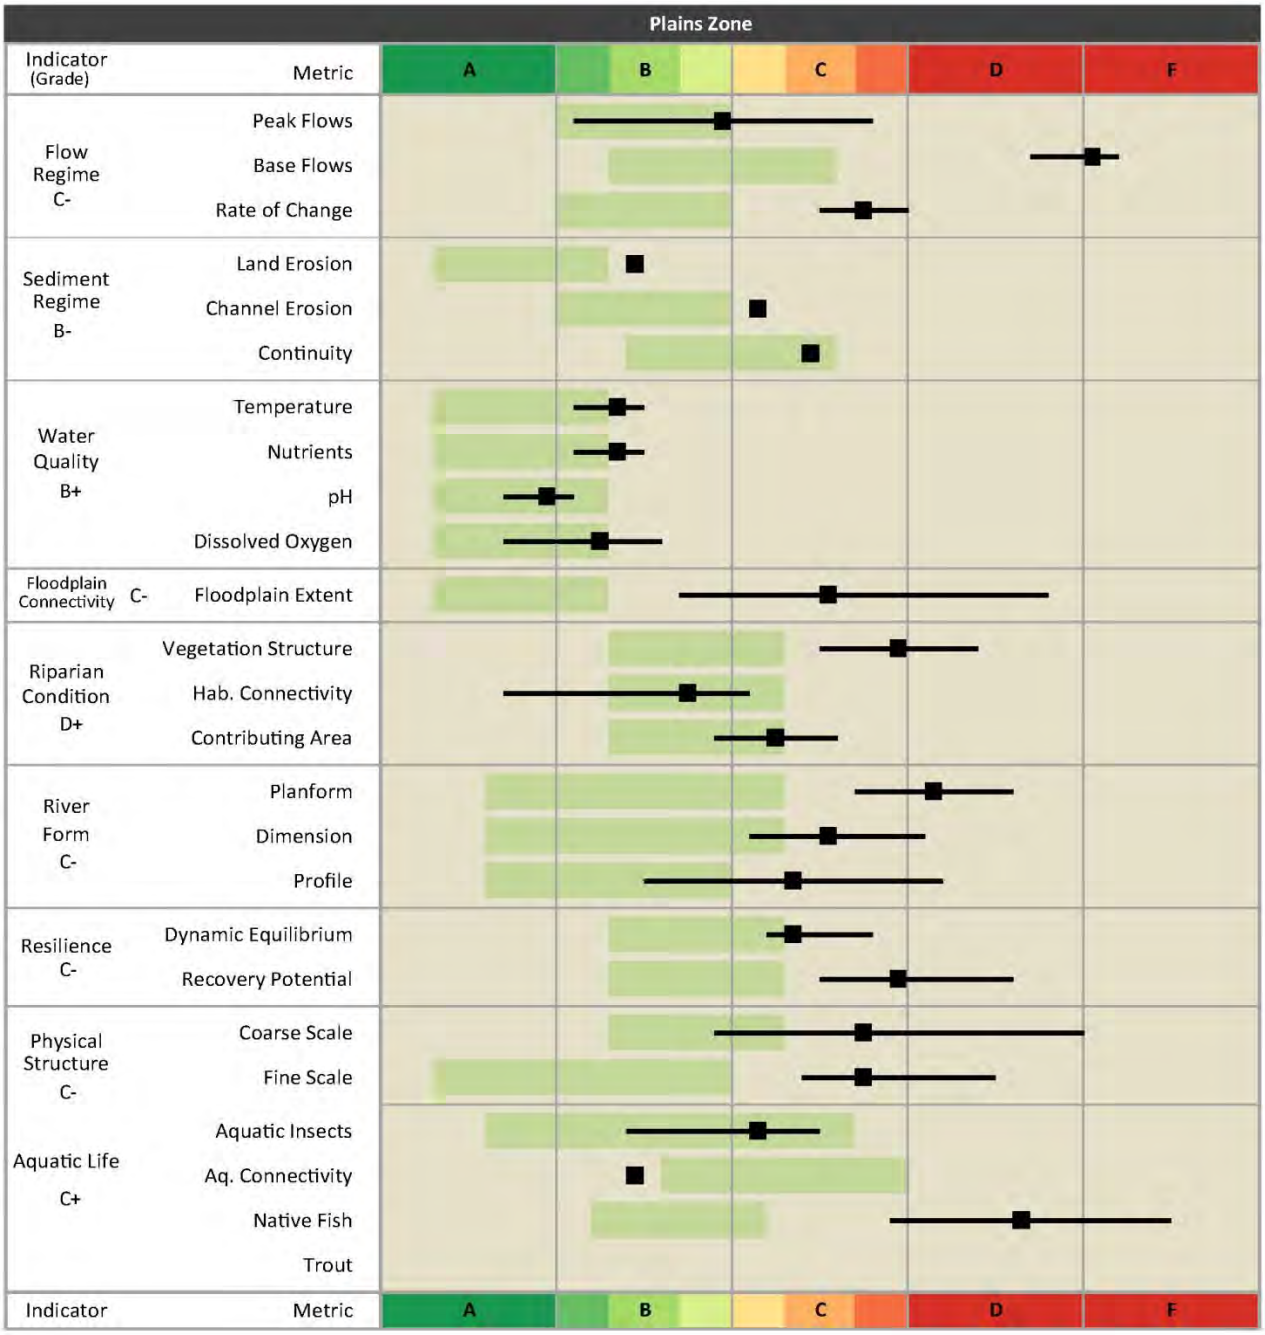
Figure 5.9: While the healthy brown trout populations in the Urban zone indicate suitable habitat conditions for cold water species, their influence as predators on the declining populations of native fish is not well understood (photograph courtesy of Colorado Parks and Wildlife).

5.5 Plains zone

Differentiation between the Plains zone and the Urban zone is largely based on land-use patterns and development rather than inherent differences in ecosystem properties. Historically the river would have continued to braid, with waters becoming warmer and bed material finer. A stretch of multi-thread channel exists in the broad floodplain preserved at Colorado State University's ELC south of Prospect Road, but most of the river has been simplified (Figure 5.10). Diversions continue to impair river health (except for fish movement due to recent installation of fish passage), as do berms, channelization, bank armoring, and impervious surface runoff upstream of this zone. Basically, all the land-use modifications that come primarily with mineral resource extraction in the floodplain influence this zone (Table 5.5).

Figure 5.10: In the Plains zone the river has some opportunity for good connectivity with the floodplain which results in higher function through the system and allows for periodic flooding of the riparian zone (left). However, through much of the Plains zone the channel is continues to be highly confined by ponds and berms on either side drastically altering its function (right).

Table 5.5: Metric grades in relation to recommended ranges for the Plains zone. Recommended ranges (green bars) represent expert opinion for reasonable and practical potential metric grades given existing land and water- use constraints. Points (square black boxes) present the average grade for the given metric for this zone. The black lines show the range of results across the reaches within this zone.



Flow and sediment

As in the Urban zone, most metrics in the Plains zone have grades below the recommended ranges. Flow regime scores on the Plains zone were similar to those in Urban zone, but the peak flow metric received a B- compared to C. The better grade in the Plains zone does not reflect an actual increase in peak flow hydrology, but rather a reduction in bed material size that potentially increases the ability of peak flows to mobilize stream bed material and flush it through the system. Therefore, even though observed magnitude and frequency of peak flows have been lessened, they are still considered sufficient for basic streambed maintenance functions in this zone. On the other hand, functions affected by diminished peak flow hydrology, such as floodplain activation, recharge, and riparian support are significantly reduced. Base flow conditions are at their worst on the Plains zone, where frequent dry-ups and critically low flows severely limit aquatic life. Grades for all these metrics are lower than the recommended ranges.

The sediment regime scored a C+ in the Plains zone. The grade is driven by the channel erosion metric, which fell below the recommended range at a C+. Despite the river flowing through large areas of land managed as conserved open lands, bank armoring and channelization continue to impact the sediment regime. Like the Rural zone, the altered sediment supply is also creating accelerated bank erosion in areas without riprap due to the river's increased capacity to transport sediment.

Because much of the area in this zone is conserved land, the opportunity may exist to better allow the river to adjust but cumulative impacts of multiple diversions upstream severely impact the river's flow regime directly influencing the sediment dynamics. Opportunities for improving sediment metrics in the Urban zone are limited due to encroachment of development and the need to protect infrastructure near the river. The City of Fort Collins Utilities' Stormwater Management Program enforces and implements several management practices aimed at reducing stormwater runoff impacts to the river. Erosion control practices during construction help to reduce undesired sediment from entering the river.

Water quality

Water quality is diminished compared with upstream zones but remains relatively high through the Plains zone. In this zone, grades for nutrients and temperature are lower than the recommended ranges, while dissolved oxygen scores hover at the lower limit of the recommended range. The relatively lower grades reflect the combined influences of urban stormwater runoff, treated wastewater effluent, and lower river flows.

River channel *(river form, resilience and physical structure indicators)*

River form is highly altered from the historic condition in the Plains zone. Approximately 70-80% of the river length is channelized or bound by berms, and more than half of it is armored. Floodplain extent is severely limited as a result. Like the zones upstream, the dependence on artificial measures to maintain river form indicates poor resilience and limited recovery potential. The channelized river form and lack of woody material are responsible for impaired physical structure and lack of habitat diversity on most of the zone, where most reaches exhibit homogenous run habitat and few riffles, pools, side channels,

or backwater features. Channel structures such as bridges, dams, and weirs are fewer and spread farther apart compared to the Rural and Urban zones, but they are still the most important stressors to river form, structure and resilience on the sub-reaches where they do occur.

Riparian corridor *(floodplain connectivity and riparian condition indicators)*

The Plains zone holds some excellent patches of dynamic, resilient riparian habitat, such as that in the Riverbend Ponds Natural Area and at the ELC. Yet these are few and far between because ponds and berms (along with the Boxelder Treatment Plant), narrowly encroaching on the channel seriously impair riparian vegetation condition throughout much of this zone. Vegetation structure and complexity is well below the recommended range, at the low end of the C range. This indicates that vegetation has only a tenuous hold on healthy functioning.

The ELC has some of the highest-quality—or at least most extensive— riparian habitat in the SOPR study area (Figure 5.11). In this reach, the split channel creates a wide riparian zone. Although variously wooded and an outstanding resource, much of the habitat in the interior is essentially "high and dry" and disconnected from the river; therefore, its ability to support river health is diminished.

Figure 5.11: In the Plains zone, a stretch of multi-thread channel exists in the broad floodplain preserved at Colorado State University's ELC south of Prospect Road (above). The river in the ELC is a contrast to the simplified river form that exists in much of this zone.

Habitat connectivity was generally good and within the recommended range in the Plains zone. Reductions in connectivity were usually caused by the narrowing of native riparian vegetation – most commonly as the result of gravel mining. Prospect Road also crosses the river and riparian habitat and

creates a break, but fortunately the bridge underpass provides a protected corridor for organism movement and passage for water and materials.

The contributing area of reaches in the Plains zone were on the average just within the recommended range for maintaining river health. Open, vegetated habitats cover most of the areas that have not been mined and converted to water storage. Because most of the ponds are isolated from the river, they do not contribute positively to river health, but they also do not cause major ongoing negative effects on the river and the remaining riparian habitats.

Aquatic life

Aquatic insect grades range from B to C, and all reaches scored within the recommended ranges. Native fish grades range from C- to F in the Plains zone. Most native fish species are either extirpated from the zone or at risk. Trout were not graded in the Plains zone because this warmer segment of river is not natural habitat for these cold water-fishes. Aquatic habitat connectivity is greatly improved in this zone, compared to the Rural and Urban zones,largely due to the installation of fish passage at one of the major diversion dams. Because aquatic habitat connectivity is greatly improved on the Plains zone compared to reaches upstream, the average grade exceeds the recommended range. Nevertheless, barriers downstream of the study area limit upstream migration of native fish, so when populations do crash locally, it is difficult or impossible for them to recover naturally (through immigration from downstream waters).

Many factors are negatively affecting native fish species richness in the Plains zone and contributing to their decline, particularly poor base flow conditions and seasonal dry-up of certain reaches. As in the Urban zone, poor floodplain connectivity diminishes habitat quality for native fish that require access to the floodplain to carry out basic life history functions. Numbers of brown trout have also recently increased above historic levels in upstream portions of this zone suggesting marginally cold thermal conditions for warm water native species. Finally, the proportion of other warm water non-native species has increased in this zone. Many of these species may indirectly compete with native species for resources, while others such as largemouth bass suppress native populations directly through predation.

While the results from the aquatic insect evaluation for the Plains zone produced an overall B- grade, many of the sub-metrics detected a general increase in stress in a downstream direction. An evaluation of taxa that are sensitive to stressors indicated that there was some decline in the richness of these species; however, the Clinger Taxa sub-metric produced scores that were identical with the rest of the study area. Despite the variable responses among some metrics, a distinct reduction in specialized feeding groups (demonstrated by the Predator and Shredder Taxa sub-metric) was observed, while the abundance of taxa that are usually tolerant to disturbances increased in the most downstream portion of the study area. In general, negative impacts affecting aquatic insect communities appeared to increase in the downstream portions of the Plains zone, yet evidence suggests that aquatic conditions were adequate for maintaining moderately healthy communities of these organisms.

5.6 Potential opportunities for improving river health

The goal of this section is to identify the types of opportunities where the City may be able to most effectively improve river health and resilience by strategically applying its resources. The following section is provided as a high-level description of management possibilities rather than a site-specific set of priority actions.

Flow

Achieving improvements on the river will be challenging since the amount and timing of the multiple diversions on the Poudre River are governed by water rights that are administered by the State according to strict legal procedure. Water rights administration is largely outside the sphere of influence of the City. The existing (and future) diversions on the Poudre River support local food production and the water needs of our homes, businesses and institutions. Concepts for improvements to the river will need to consider these historic rights and may require some type of compensation if historic diversions are not maintained, operations become more costly, or physical structures need to be altered. There may be opportunities for improvements that minimize impacts to these water users (as described below), but doing so will take collaborative efforts with many stakeholders.

From the Canyon zone to the Plains zone refining water management operations to better mimic the natural flow regime would improve river health and grades. In the Canyon zone, a more natural flow regime would especially benefit the rate of change metric. Out of the canyon, water management becomes increasingly complicated due to the multiple diversions for irrigation and municipal water needs, including those by the City of Fort Collins. Known dry up locations could be good focal points for collaborative flow related initiatives aimed at reducing the frequency and severity of complete dry-up events during critical low flow periods. Water exchanges and creative uses of local storage could be effective tools for improving base flow conditions.

Improving base flow in the Urban and Plains zones would require major changes to water management and diversion operations in order to elevate the current grade ranges of D to F+ to the recommended C (or greater). Achieving this level of improvement is highly aspirational, but even small improvements could make a big difference in the health of the aquatic habitat. Improving the rate of change metric from C- to the recommended minimum B- may be more attainable goal since this could be accomplished by ramping diversions so that river flows change less drastically over short periods of time. For example, local storage releases to diversion points lower on the river could be made in a manner that avoids sudden flow changes and yet maintains the same volume of delivery. Improving peak flows (mention zones if you want) may also prove to be challenging, since these flows are typically diverted throughout the watershed to fill local storage reservoirs and provide local irrigation and municipal water needs.

However, there could potentially be better coordination among local water users and the river administrators to consider short periods during which administration of the river could potentially be implemented in a way that would allow higher peak flows to provide ecological benefits to the river. For example, in particularly high snowpack years when there is consensus that there will be more than

enough runoff to meet all the basins water needs, much of the diversions could be curtailed for 1-3 days during the projected highest runoff period to allow for better flushing flows. Again, this type of operation would require close and willing collaboration with the various stakeholders in the basin.

Water Quality

Water quality is quite high in the Canyon zone. The metrics that are most impaired— temperature and dissolved oxygen—could possibly be improved by changing dam and reservoir operations, but it is unclear which changes should be implemented to bring about the desired effects. Detailed study and modelling would be necessary to make prescriptions for actions to improve water quality in the Canyon zone, because unguided action could exacerbate problems.

Downstream of the canyon, opportunities for improving water temperature seem technically feasible but again it would probably involve changing water operations. Water operation changes are notoriously challenging and usually expensive, therefore, improvements in temperature are unlikely in the near term.

There are irrigated agricultural lands influencing the SOPR study area, specifically in the North Fork watershed, within the Rural zone, and near the Dry Creek and Box Elder tributaries that feed the Poudre River. Nutrient metric grades indicate impacts from irrigated agriculture are currently a low stressor to the Poudre River. If water quality monitoring efforts indicate pollution inputs from irrigated lands, then best management practices could be recommended to improve agricultural runoff and decrease nutrient loading. The City has no control over privately owned agricultural land so stakeholder partnerships and participation would be necessary to mitigate impacts from agriculture.

River channel *(river form, resilience and physical structure indicators)*

The physical setting is described through the four indicators: river form, structure, and resilience. In the Canyon zone, physical constraints limit the range of improvements that could occur and because a large proportion of the physical impairment in the zone is tied to the highway and dams, there is little opportunity for improving these aspects of river health.

Below the canyon, there are a number of technically feasible ways that the physical characteristics of the river could be improved. Creating bridge designs that incorporate appropriate bridge spans and adding floodplain culverts could reduce river health and resilience impairments. Increasing floodplain connectivity near bridges in conjunction with floodplain culverts could help ease flow constriction through bridges, improve sediment transport, and provide drainage if the bridge were to become clogged during a large flood event. These actions would greatly increase resiliency in the face of large flood events. Reclaiming abandoned roads and removing non-essential bridges, constrictions, and relict in-channel structures may be feasible in the areas where they exist and these improvements would be a benefit in any of the zones.

Even in the most urban areas, potential opportunities exist for improving the river's physical form and function. In general, offsetting berms (when possible to beyond the 100m riparian zone), setting multi-use paths further back (when due for replacement), removing or offsetting bank armor (unless it is necessary to protect infrastructure), restoring natural stream form in undeveloped open areas could greatly improve river health and resilience. These actions would improve floodplain connectivity, river form, resilience, and structure by decreasing entrenchment and allowing the river to adjust planform. This would allow the river's energy to decrease during floods by spreading water over the floodplain, slowing velocities, and increasing sinuosity. These mechanisms of dealing with floods are less expensive and more resilient, over the long-term than trying to make channels strong enough to resist the high energies generated by flood flows. It also allows the river to be dynamic, which is important for maintaining structural complexity, habitat diversity, and healthy riparian vegetation.

Some berms may be able to be removed outright. For instance, many of the naturalized open spaces and Fort Collins Natural Areas are channelized or have berms close to the channel where their close proximity may not be critical to health or safety. Rehabilitation or removal of these features would open floodplain access, restore river form, and improve riparian condition. Furthermore, these undeveloped areas could be utilized as areas where floodwaters could spread, drop sediment, and slow down to help protect entities downstream. The City of Fort Collins Natural Areas Department recently completed the successful removal of the Josh Ames diversion and associated riparian restoration projects at Sterling and McMurry Natural Areas (just upstream and downstream of Shields Street respectively). Similar beneficial opportunities may exist elsewhere, but the main challenge is that these types of projects are expensive and difficult to implement given the various engineering and regulatory issues they present.

When riprap is necessary, the way it is installed can lessen its negative effects. For instance, offsetting and burying riprap right at the protected structure may provide increased resiliency during large flood events by allowing the river to erode banks and dissipate energy. Furthermore, during large flood events rivers will move and possibly even avulse into a new channel. By allowing the river as much room as possible to move during large flood events, management works with natural processes instead of trying to halt them. Ignoring natural processes may increase risk of harm and costly impacts during high floods in the very areas we are trying to protect.

Riparian corridor *(floodplain connectivity and riparian condition indicators)*

In the Canyon zone, riparian condition is generally good, and since the small-degree of impairment here is directly related to encroachment by the highway, there is little opportunity for improvement other than maintaining best management practices, addressing noxious weed issues, collecting litter, etc. Most of the practices must be carried out by individuals and entities other than the City.

Downstream of the canyon, areas with rural-land use or light agriculture have some capacity for maintaining at least patches or strips of native riparian vegetation alongside existing uses. In fact, some of the forested patches in light agricultural areas scored among the highest in the entire study area, especially near the canyon mouth. These forests have fewer problematic woody species and better

canopy structure than most of the habitats downstream. Stewardship and riparian restoration may, therefore, be potential options for improving riparian condition if landowners are interested. The average riparian condition grade on areas mapped as rural, pasture, or light agricultural land use is D+, but the range extends to C+. This range suggests that there could be potential for improvement at some lower condition sites. The City does not own or manage lands in the Rural zone, so improvements to riparian habitats in that zone would be voluntary, landowner-led efforts; although the City could potentially help support improvements through a variety of means.

In the Urban and Rural zones, improving the character of foundational processes such as opportunities for flooding, scour, and deposition would drive a cascade of positive influences throughout affected riparian areas.

Other potential riparian improvements include improving the recruitment of large woody material and leaving woody material in the river to the greatest extent possible. In areas where the surrounding and downstream land is relatively undeveloped, increasing floodplain extent and tolerance for some degree of channel migration in naturally forested areas is also a mechanism for improving recruitment of woody material recruitment. These refinements in management would increase structural diversity and aquatic habitat heterogeneity. But woody material can also cause damage to bridges, dams, berms, and other structures, so there will always be some need to manage how and where wood is allowed to contribute to river dynamics. Maintenance strategies that employ selective, rather than complete, removal of wood could provide river health benefits, while still protecting infrastructure.

Aquatic life

One of the biggest impacts to aquatic life in the study area is habitat fragmentation and migration barriers caused by the diversion dams. Construction of fish passageways or other passage mechanisms would lessen the impact of dams on fish migration, and such measures would elevate the aquatic habitat connectivity scores (Figure 5.12). Facilitating fish passage at diversion dams would also allow fish to access the mosaic of habitats vital to different life history attributes, and would allow recolonization following localize population crashes. Such measures would seemingly lead to increases in fish populations and certainly fishery health.

Figure 5.12: Recently installed fish passageway at the Fossil Creek Inlet Ditch just downstream of Prospect Avenue.

Across aquatic life metrics and river reaches aquatic habitat could be enhanced by improving flow metrics as discussed above. Low flows and dry ups during summer and winter months are known limiting factors to aquatic life health. Improvement to flow characteristics would mitigate thermal

stresses, support desired dissolved oxygen levels, increase the amount of aquatic habitat, flush interstitial spaces for aquatic insects, and reduce the habitat fragmentation caused by dry ups.

Projects increasing habitat complexity, especially those which result in increased pool habitat, would definitely bring benefits to aquatic life. Use of large wood material and other scour providing materials could lead to increases in habitat scores and greater fish numbers and health. Promoting habitat at the tributary nodes of storm water return, irrigation return, and other small tributaries for production of some native fish species paired with active translocation of species would further improve the aquatic species populations. Continued stocking and evaluation of rainbow trout recruitment and survival in the face of whirling disease and high brown trout densities is an objective of Colorado Parks and Wildlife for the Poudre and similar Front Range rivers.

Aquatic insects have evolved and adapted to the healthy aquatic conditions that historically persisted in Colorado streams for eons. Many of the human activities in the Poudre River watershed alter water quality or habitat resulting in a shift in aquatic insect community structure or function. Accurate and consistent sampling and monitoring of aquatic insects is important for the documentation and evaluation of stress-related shifts in aquatic life over time. Long-term biomonitoring studies also provide valuable information that can be used to identify trends and help distinguish between natural variation and impacts from anthropogenic stressors which could then potentially be addressed through management actions.

6 Looking forward

A primary goal of the SOPR is to foster management approaches that consider river health and function in a more comprehensive fashion. The SOPR takes a holistic and science-based approach, and provides a platform for evaluating operational, management, and policy options for preserving or enhancing river health. It is a tool for weighing outcomes and evaluating tradeoffs in the currency of river health. This first SOPR assessment also serves as a benchmark for monitoring river health changes into the future.

The SOPR is intended to serve to enhance the collective understanding on the potential impact of projects or decisions and to provide a means to effectively evaluate and prioritize opportunities, measure progress, and communicate results (Figure 6.1).

Figure 6.1: Colorado Water Institute staff Reagan Waskom and MaryLou Smith lead a community dialog at the annual Poudre River forum.

6.1 The future of the State of the Poudre project

Continuing this project through repeat assessments on a periodic basis (3-5 years) allows it to serve as a tool for following a "plan, do, check" management approach. Using this strategy, the results of SOPR assessments can first be considered by City staff and collaborators. Next, reach and metric specific goals, scores and stressors can be linked to create management priorities (Figure 6.2). Then the subsequent version of the State of the Poudre can help us reflect, or "check" on the progress we are making towards our goals.

Figure 6.2: Diagram illustrating the process whereby the SOPR may be applied to inform management priorities and track river health trends over time.

The metrics included in this study are each distinct and therefore need to be measured on specific time scales. To support subsequent iterations of this project data for some metrics should be collected annually, or perhaps data gaps filled. Other metrics change more slowly and need to be measured on less frequent intervals. These metrics may not be revisited until the next full assessment. The following section presents a list of recommendations developed by this project team of potential methodological improvements and enhancements that could be made in the future.

6.2 Potential improvements to the SOPR methodology and data

- While maintaining this existing approach for evaluating peak flows, a potential addition for understanding this metric would be to evaluate new locations for scour analysis thresholds, collect evidence of "flushing" using tracer rocks, and/or use point flow model to understand local conditions at discrete (diversion) points. Also a quantitative approach could be developed for evaluating flows in the Canyon zone.
- Work with collaborating organizations to catalyze a landscape-scale fish movement study to improve understandings of the relationship between fishery health, movement and the suite of stressors. This study would not become a regular part of the SOPR, rather it would provide

important insight and additional evidence to supporting various scores associated with fish and fish habitat.

- Continue annual insect data collection, generally during both spring and fall (including new data points initiated in 2016 to inform this project). Review 2016 fish data including the sampling location in from the Rural zone. Conduct field assessment of valued riparian sites not assessed through a 2016 on-site evaluation for this baseline assessment.

Wrap Up

For the first time, the City of Fort Collins has a comprehensive baseline of river condition. From here forward, this tool will help the City and the region measure efforts to sustain, maintain, and improve river health. Ultimately, the SOPR is an act of faith in the future and an example of the City's commitment to the plan-do-check-act cycle (Figure 6.3).

Ultimately, a well-stewarded river contributes to the long-term success of our community, which has for over a century depended on the Poudre. As challenges to water security and ecological health mount over the next century – it will become ever more important for decision makers to have powerful tools like the SOPR at their disposal, to inform critical decisions. With good tools, and some hard work, our community will be in a better position to sustain the cherished values of the beloved Cache la Poudre.

Executive Summary

Introduction

The City of Fort Collins is located 65 miles north of Denver in Larimer County, between the Rocky Mountains foothills and the Eastern Plains of Colorado. Fort Collins Utilities (FCU) currently serves about 75% of Fort Collins' residents and businesses. The FCU service area boundary for water, which does not coincide with Fort Collins city limits, is landlocked by neighboring water districts. Current estimates for the FCU service area show an increase in population to about 178,000 by 2065. Fort Collins is home to Colorado State University and a few large commercial enterprises.

The Fort Collins Water Supply Vulnerability Study (WSVS) was performed to investigate the ability of the FCU water supply system to meet future demands under current policy criteria and level of service goals when subjected to alternative hydrologies and various risks and uncertainties. The WSVS compiled alternative hydrologies, demands, and infrastructure risks and uncertainties into risk scenarios, resulting in a broad range of potential future conditions. The performance of the Fort Collins system under these risk scenarios was evaluated to inform under what future conditions the FCU water rights portfolio, raw water infrastructure and water supply policy and planning efforts are most vulnerable.

This project was performed by Stantec Consulting Services, Inc. under a contract with the City of Fort Collins. RTI International was a subconsultant to Stantec for hydrologic analyses and demand tool development.

Water Resources System Model

The WSVS involved risk-based water resources planning analyses that required a robust modeling platform to simulate the performance of FCU's raw water system under a wide range of possible future conditions. The modeling system used for the WSVS consists of three separate models: the Colorado-Big Thompson Quota Model (CBTQ), the Poudre Basin Network Model (PBN) and the Fort Collins System Model (FCSys).

- The CBTQ Model was developed by Northern Water to estimate annual quotas of C-BT and Windy Gap water for its allottees based on hydrology and current operations.
- The PBN Model is a MODSIM model that simulates water supply infrastructure and operations by municipal, industrial, and agricultural entities in the Poudre River basin and the lower South Platte River basin below the Poudre River confluence near Greeley. It was originally developed by Resource Consultants in 1985 for the Fort Collins Drought Study, but has been enhanced by Fort Collins, Northern Water and Greeley over the years to serve a number of purposes.
- The FCSys is a MODSIM model developed by FCU that simulates the FCU water supply system under various water demand, water rights, infrastructure and operational scenarios. The FCSys simulates city water deliveries, deliveries to large contractual users (LCU), return flow obligations

from the use of converted agricultural water rights and various other operations of the FCU water supply system.

These models were run in sequence through a Data Management System as shown in **Figure ES-1.** The system is semi-automated and includes the ability to export FCSys output as PBN inputs and vice versa.

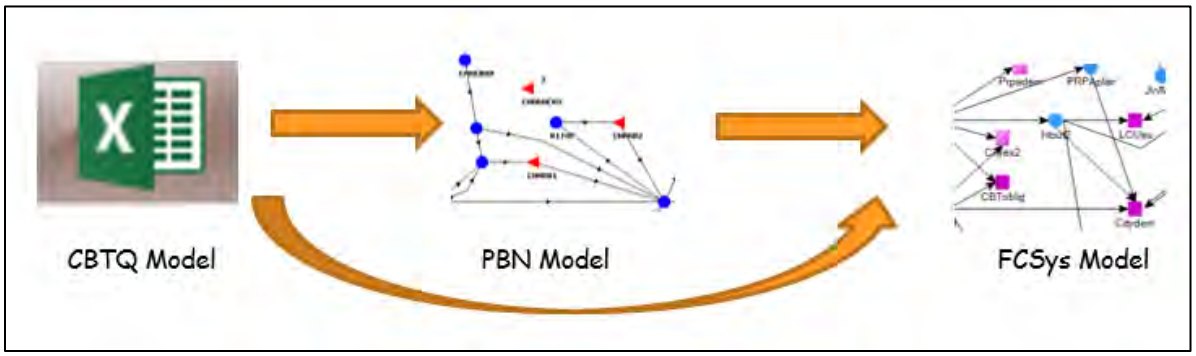

Figure ES-1 FCU Modeling System Overview

Fort Collins and other agencies have used previous versions of the PBN and FCSys models for past water resources planning and decision-making. The WSVS modeling system was not developed to re-evaluate any previous planning studies and it does not simulate flows in streams that could be affected by water development projects in the Poudre River basin. This modeling system was developed to identify and prioritize future risks for which FCU should be planning.

The WSVS used the FCU modeling system to evaluate FCU water supply system performance. “System performance” is defined as the ability to meet customer demands and satisfy adopted water supply planning policy criteria. For FCU, the Water Supply and Demand Management Policy (WSDMP) establishes an objective of:

- meeting demands calculated using a per capita use factor of 150 gallons per capita per day,
- through the 1-in-50-year drought,
- with no shortages or water restrictions,
- while maintaining a minimum of 20 percent of annual demand in reservoir storage at all times (storage reserve factor).

As part of the WSVS, the performance of the FCU water supply system was quantified using measurable parameters (metrics) with target values based on the criteria defined in the WSDMP (level of service goals). The performance metrics and level of service goals were identified and calculated as part of the modeling system outputs. Risk-based water supply planning commonly considers three categories of performance metrics: reliability metrics (i.e., measures of how often certain conditions occur), resilience metrics (i.e., how long certain conditions occur) and vulnerability metrics (i.e., how severe certain conditions area). Many specific reliability, resilience and vulnerability performance metrics were identified

to help quantify the impacts of risks and uncertainties to the FCU water supply system. As the WSVS progressed, FCU staff found that the following four performance metrics were most useful for identifying the impactful risks.

- Average annual total demand shortage in years when shortages occur
- Reliability (i.e., frequency) of maintaining 20% of annual demand in storage (storage reserve factor)
- Percentage of time in any level of water use restrictions based on the current planning policy criteria
- Reliability of meeting indoor demand

Hydrology

Synthetic sets of potential future hydrologic model inputs that include natural variability and large-scale shifts in precipitation and temperature trends due to potential climate change were generated for use in the Fort Collins Modeling System.

Figure ES-2 provides an overview of the process used to generate hydrologic datasets for the WSVS. Application of this process resulted in 20 sets of 100 sequences of natural hydrologic variability (referred to as a "trace"), with each set representing a particular future climate condition. Future climates were described by the offset of temperature and precipitation from historical conditions. Based on review of previous climate change studies for the Front Range region, the temperature offset ranged from 0 to plus 8 degrees F compared to average annual 1981 to 2010 observed temperature, and the precipitation offset ranged from -10% to +15% of average annual 1981 to 2010 observed precipitation.

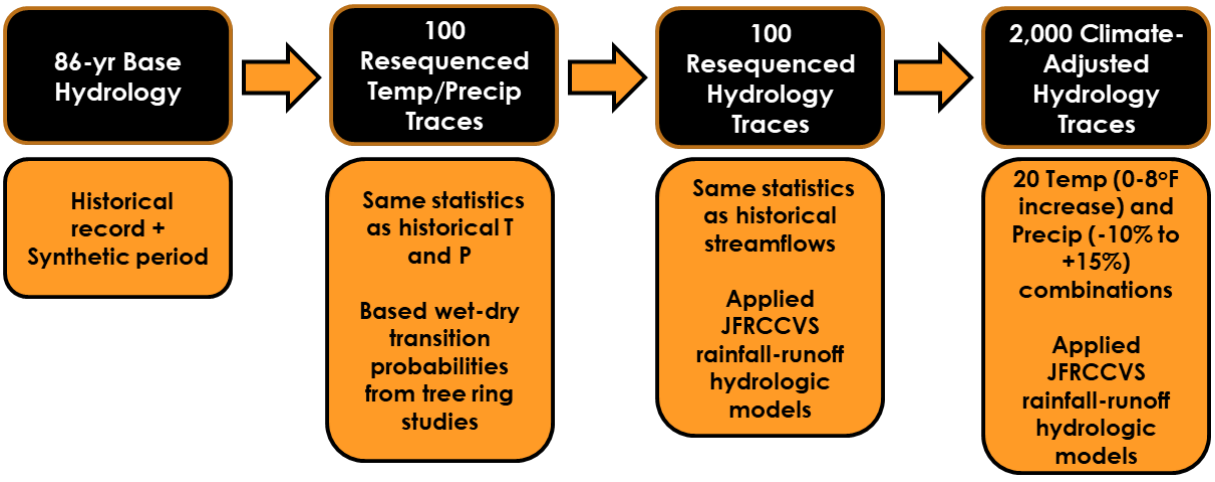

Figure ES-2 Overview of Hydrologic Analysis Process

Note: JVRCCVS = Joint Front Range Climate Change Vulnerability Study

Temperature and precipitation changes in the range adopted for the WSVS were found to have significant effects on streamflow contributing to FCU water supply. The hottest/driest climate condition (T=+8, P=-10%) reduced the Poudre River at the Canyon Mouth mean annual streamflow by an average of 30% for the 100 hydrologic traces, compared to the non-climate adjusted traces. The coolest/wettest climate condition (T=0, P=+15%) increased the Poudre River mean annual streamflow by an average of 39% for the 100 hydrologic traces, compared to the non-climate adjusted traces. This is shown in **Figure ES-3**.

In the past, FCU has used a 6-year critical period within the 86-year model simulation period to determine the 1-in-50-year drought for water supply planning. Hydrologic inflows were based on synthetic runoff data. This 6-year critical period for the Poudre River at the Canyon Mouth has an average annual runoff of 196,090 acre-feet per year (AFY). The 100 hydrologic traces in the WSVS hydrologic dataset for the unaltered historical climate conditions (T=0, P=0%) have an average 6-year critical period flow at this location of 191,343 AFY, which is a 2% reduction. The hottest/driest climate condition (T=+8, P=-10%) produces an average 6-year critical period annual streamflow that is 31% less than the critical period streamflow currently used for planning. The coolest/wettest climate condition (T=0, P=+15%) produces an average 6-year critical period annual streamflow that is 38% more than the critical period streamflow currently used for planning. This is important when interpreting the vulnerability study results relative to current water supply policy criteria that are based on the 6 year long, 1-in-50-year drought in the synthetic runoff data. When considering the full set of 100 hydrologies times 20 climate scenarios generated for the WSVS, there are traces which capture more severe and more frequent critical periods than the historical 6-year critical period used in previous water supply planning to represent the 1-in-50 year drought. Additionally, there are traces in the WSVS that do not see critical periods as severe as the historical.

		Delta P				
Basin	Delta T	-10%	-5%	0%	7%	15%

Figure ES-3 Average Annual Flow Volume for Hydrologic Traces for All Climate Conditions

Note: Each cell shows the mean of the average annual flows for the 100 traces with the corresponding T/P combination expressed in AFY and as a percentage of the average annual flow for the T=0, P=0 combination.

Water Demands

Future water demands for general residential and commercial customers in the FCU service area were estimated using a new Demand Estimation Tool developed for this project. The Demand Estimation Tool consists of individual linear regression models, each developed for the following groups of water customers: single family and duplex, multifamily, commercial small, commercial medium, and commercial large customers. It was developed using processed historical customer-level water use data from 2001-2016.

Three demand scenarios were developed by FCU for use in the WSVS: City Plan 2, City Plan 3 and City Plan 3 plus 20%. The first two demand scenarios are based on the most likely proposed future development scenarios for 2070 developed as part of the Fort Collins City Plan update. The median average annual water demand in 2070 under City Plan 2 assumptions, including the effects of climate change, is 37,700 AFY. The more aggressive growth assumptions in the City Plan 3 scenario result in a median total water demand of 39,200 AFY, for an increase of 4% compared to City Plan 2. The City Plan 3 Plus 20% scenario increased both the general residential and commercial portion of the total demand and a portion of the Large Contractual User demand by 20%. This resulted in a median total water demand of about 45,200 AFY. **Figure ES-4** compares the total annual demands for these three scenarios. The average annual demand for 2065 developed from previous FCU planning studies is 40,629 AFY; this is referred to as the “baseline demand” in this study.

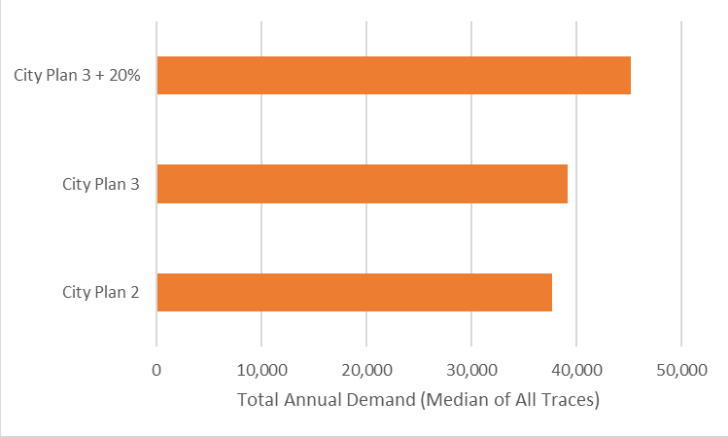

Figure ES- 4 Total Annual Demand in 2070 Including Climate Change (Median of All 2,000 Traces for Each Development Scenario)

Note: Average Baseline demand = 40,629 AFY

Risks and Uncertainties

The purpose of the WSVS is to identify the vulnerability of the FCU water supply system to a range of risks or threats that could occur in the future and factors that cannot be accurately forecasted. Risks and uncertainties that could affect the future performance of the FCU water supply system were brainstormed in workshops held at Fort Collins Utilities and Northern Water. Identified risks and uncertainties were organized in the following categories that span the various aspects of the FCU water supply system.

- ***Climate and Hydrology*** risks relate to weather variability and other hydrologic factors, both short- and long-term, that can impact the potential yields from a watershed.
- ***Watershed*** risks relate to physical watershed conditions that can impact the yields available to FCU.

- ***Operational and Infrastructure*** risks relate to how FCU delivers physically and legally available water to its treatment facilities.
- ***Administrative and Legal*** risks relate to conditions, regulations, or policies that could impact the legal allocation or availability of water supplies.
- ***Demand*** risks relate to changes in required volume, timing, and quality of water that will need to be delivered to water treatment facilities to meet customer needs.

Some risks are long-term, or chronic, and would persist indefinitely and affect all future years. Other risks are short-term, or acute, and would only occur for a short period of time (e.g., several months or a few years). Although long-term and short-term risks could have very different impacts on the FCU raw water system performance, both types of risks were assessed together in the WSVS.

The identified risks were rated as part of the prioritization process. Individual risks were rated by assigning a 1 to 5 score for both likelihood (possibility of the risk or uncertainty occurring) and impact (consequences to the FCU/C-BT water supply system if the risk or uncertainty were to occur). The composite score was calculated by multiplying the likelihood score by the impact score and was then used to prioritize risks. The prioritized risks and uncertainties were organized into five major threat groups that span the various risk categories. These threat groups are: climate change, demands, critical outages, enhanced environmental stressors and shared infrastructure (i.e. risks or uncertainties due to lack of infrastructure ownership by FCU). The risks and uncertainties selected for analysis in the WSVS are shown in **Table ES-1.**

Table ES-1. List of Key Risks and Uncertainties Prioritized for Simulation

ID	Risk or Uncertainty Name	Threat Group	Description
O1	Outage - 24 Pipeline	CO	Short term outage due to flooding, landslides, wildfire, etc.
O2	Outage - 27 Pipeline	CO	Short term outage due to flooding, landslides, wildfire, etc.
O3	Algal Blooms	EES	Algal blooms in storage reservoirs and rivers increases water quality issues and potential treatment problems.
C1	Longer duration droughts	CC	Multi-year and/or more severe droughts occur in the future that are not captured in the observed record.
A1	New Regulations	EES	New regulations (either federal or state) impact availability of yields from existing water rights.
W1	Wildfires	EES	Wildfires occur, causing a variety of impacts on water quality, runoff and threats to infrastructure.
C3	Change in precipitation type - Hydrology	CC	More precipitation falls as rain instead of snow during the Fall and Spring.
C4	Changes in frequency/ magnitude of precip events - Hydrology	CC	Precipitation events, particularly summer rainstorms, become less frequent and more intense.
C2	Changes in runoff timing	CC	Early higher runoff and lower late-season baseflow reduces yield from volumetric decrees that list specific diversion dates.
W2	Forest Health Degradation	EES	Forested area health decreases due to beetle kill, pollution, warming climate, etc.

ID	Risk or Uncertainty Name	Threat Group	Description
A4	Changing state administration	CC	Policies around state water administration change, impacting yields from water rights
D3	Development Uncertainty	D	The composition of development in service area (e.g. density, type, outdoor area) is different that past.
A2	Increased Basin Demands	D	Higher demands across the entire Poudre River basin (due to climate change/population growth) impact use of water rights.
O5	Outage - Horsetooth Reservoir Intake	CO	Short term outage of reservoir outlet and intake to WTP; higher risk due to lack of redundancy.
O4	Outage - Michigan Ditch	CO	Short term outage due to flooding, landslides, wildfire, etc.
D2	Water Use Changes	D	Decrease in per capita use continues and how water is used (e.g. indoor vs. outdoor) changes.
D1	Service area growth and Regionalization	D	Ft. Collins expands its service area or enters into agreements to provide water to regional entities.
A9	Elimination or Interruption of Reuse Plan	SI	Platte River Power Authority decommissions Rawhide Energy Station, effectively eliminating the need for the Reuse Plan. In multi-year droughts, water from the Reuse Plan is reduced or unavailable.
D8	Change in precipitation type - Demands	CC	More precipitation falls as rain instead of snow during the Fall and Spring.
D9	Changes in frequency/ magnitude of precip events - Demands	CC	Precipitation events become less frequent and more intense.
A3	Changes to Northern Water C-BT Operations	SI	Allocation of C-BT water through setting of the quota and ways in which C-BT water can be managed, changes in the future.
W3	Development in Watersheds	EES	Land development in watersheds (recreation, residential, O&G, mining) increases risk of water quality contamination.
D6	Hotter summer changes irrigation	D	A warmer climate increases the length of the irrigation season and hotter days increase demand during the summer.
O6	Outage - Chambers Reservoir	CO	Short term outage due to flooding, landslides, wildfire, etc.
O8	Outage - Joe Wright Reservoir	CO	Short term outage due to flooding, landslides, wildfire, etc
O11	Outage - Pleasant Valley Pipeline	CO	Short term outage due to flooding, landslides, wildfire, etc.
Note:	Threat Group ID definitions: CC = Climate Change, D = Demands, CO = Critical Outages, EES = Enhanced Environmental Stressors, SI = Shared Infrastructure		

Risk Scenarios

Risk scenarios were developed by FCU to represent combinations of future conditions for which a vulnerability analysis was desired. Scenarios are comprised of single or multiple risks and are designed to allow FCU to understand how its water resources system would behave under a range of future stressful conditions.

In general, a WSVS scenario consists of three parts:

- A climate condition, defined as one of the 20 temperature and precipitation combinations, which determines 100 hydrologic traces representing climate variability around that climate condition.
- A demand condition, defined as one of the two City Plan demand scenarios or the baseline planning demand.
- A system risk condition, defined as a combination of one or more of the risks and uncertainties.

The process for creating WSVS scenarios is shown in **Figure ES-5**.

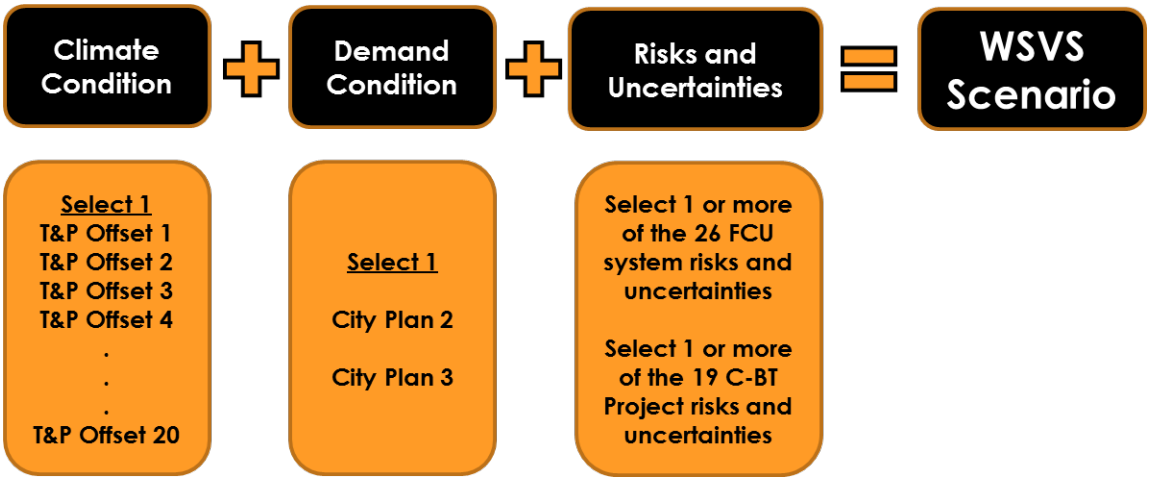

Figure ES-5. Process of Creating WSVS Scenarios

FCU Staff, in coordination with Northern Water, identified 13 scenarios for simulation, including baseline conditions. The 12 non-baseline scenarios were selected to represent a range of future conditions believed to be possible and potentially impactful to the FCU water resources system. They represent both long-term or chronic conditions (i.e., those that occur over the entire simulation period) and short-term or acute conditions (i.e., those that occur for only a short period of time). These risk scenarios are described briefly below.

- Baseline – Future conditions, including current water rights and anticipated acquisitions, current water supply infrastructure, Halligan Reservoir enlargement and a demand of 40,629 AFY.
- Climate Change Impacts – 20 future climate conditions with constant demand and no other risks.
- Loss of Storage – No Halligan Reservoir enlargement and no C-BT carryover storage in Horsetooth Reservoir.
- Increased Demands – Two City Plan based demand scenarios and one increased demand scenario beyond the City Plan development assumptions.

- No Halligan Enlargement – No enlargement of Halligan Reservoir as currently proposed.
- Poudre River System Acute Outage – Short-term outage of 24-inch and 27-inch delivery pipelines and Pleasant Valley Pipeline.
- C-BT System Environmental Impacts – Impacts on C-BT quota allocations due to environmental issues resulting from wildfires in the receiving East Slope watershed or restricted use of Horsetooth as a water source because of algal blooms.
- Poudre River System Environmental Impacts – Impacts due to algal blooms or environmental issues resulting from wildfires in source watersheds (e.g. increased sediment deposition) that would limit FCU's diversions from the Poudre River.
- C-BT System Acute Outage – Short-term loss of C-BT deliveries due to delivery infrastructure failures.
- C-BT System Long-Term Reduction - Captures possible effects of a wide range of conditions that could reduce C-BT deliveries and quotas over a period of 10 years.
- Horsetooth Reservoir Outage – Short-term outage of deliveries from Horsetooth Reservoir due to infrastructure failures.
- Reuse Plan Changes – Two options: Reuse Plan Change 1 represents 100% elimination of the Reuse Plan; Reuse Plan Change 2 represents 50% reduction in the Reuse Plan.

Vulnerability Assessment

The impacts of these various risk scenarios on the FCU water supply system were quantified using the system performance metrics tied to the current water supply planning policy criteria. Vulnerabilities were investigated in a systematic methodology based on the following steps.

1. Determine the current system's performance for the baseline demand with no climate or infrastructure risks.
2. Investigate how potential short-term climate variability and broader climate change could affect the performance of the baseline system.
3. Assess the impacts of increased demands, generated by the new Demand Estimation Tool in combination with the climate-adjusted hydrologies.
4. Evaluate the superposition of the risk scenarios with the climate-adjusted hydrologies and each City Plan based demand scenario.
5. Identify the risk scenarios with the greatest potential to adversely affect the FCU system performance.

The process for evaluating risks in the WSVS is shown in **Figure ES- 6** below.

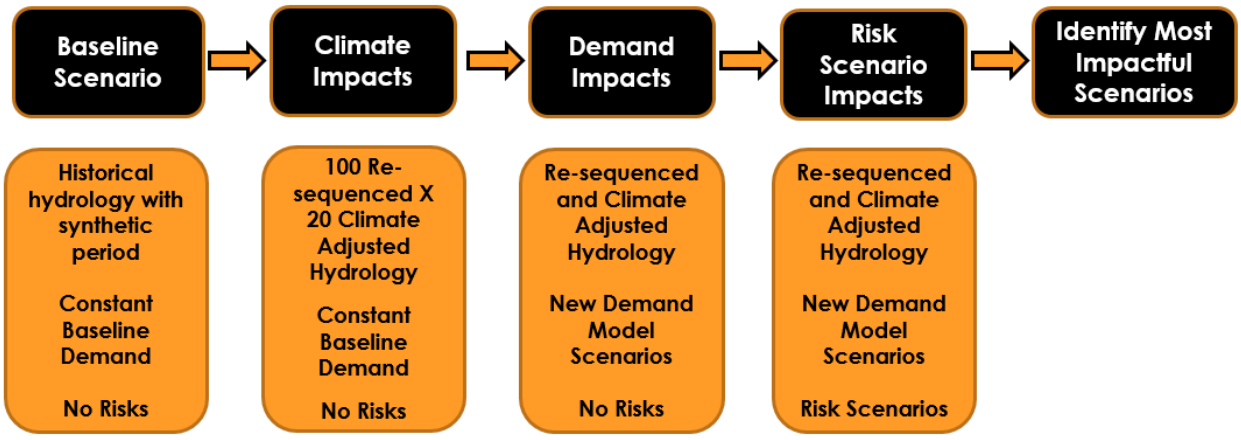

Figure ES- 6 Method for Risk Evaluation

Results showed that FCU's water system and water rights portfolio is well adapted to current climate conditions. The existing system, which includes the Halligan Reservoir enlargement, meets all demands, including Reuse Plan demands, with 99.1% reliability. Indoor demands are met 99.8% of the time. The results also showed that the system maintained the policy guideline of a 20% storage reserve factor in 97.1% of the total simulated months. Note that none of the WSVS simulations include the effects of water use restrictions.

However, system performance declines as the climate gets hotter and drier. The effect of climate on the reliability of meeting an annual demand of 40,629 AFY is shown in **Figure ES-7**. This figure shows the average percent of months in which the target baseline demand was met across the 100, 86-year traces for each of the 20 climate conditions. Comparing these reliability results to the current water supply policy of 100% reliability, under almost all climate futures, including no change in climate, the FCU system is unable to meet this level of service goal. Uncertain future hydrology is the biggest threat to FCU's future water supply, as it is heavily influenced by changing climate. Even the risk scenarios with the worst performance under current climate conditions were shown to perform better than a scenario with no system risks and an increase in temperature and decrease in precipitation.

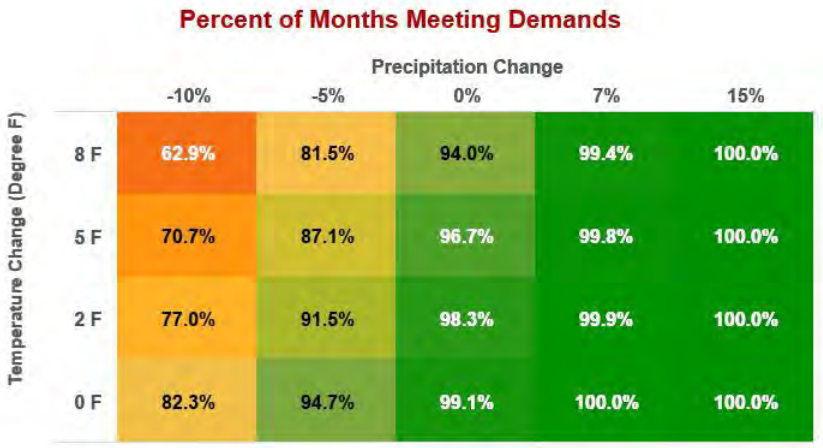

Figure ES-7. Average Monthly Reliability of Meeting Total Demands for All Climate Conditions

Simulations of increased demands showed the FCU baseline system is only moderately vulnerable to the City Plan 2 and City Plan 3 scenarios and only for hotter/drier climates. However, the City Plan 3 + 20% condition has more significant effects and represents a greater threat to FCU system performance. **Figure ES-8** shows the effects of the demand scenarios on the average annual shortage metric. This metric calculates the average annual shortage across the years when shortages occur. The figure also shows the number of years when shortages occur for each scenario. The current water supply policy establishes a level of service goal of no shortages during the 1-in-50-year drought. With the exception of significantly wetter climates, all demand scenarios have a shortage, showing the FCU system is unable satisfy this level of service goal, even for traces where the critical drought period is less than the historic 1-in-50-year drought used in previous water supply planning.

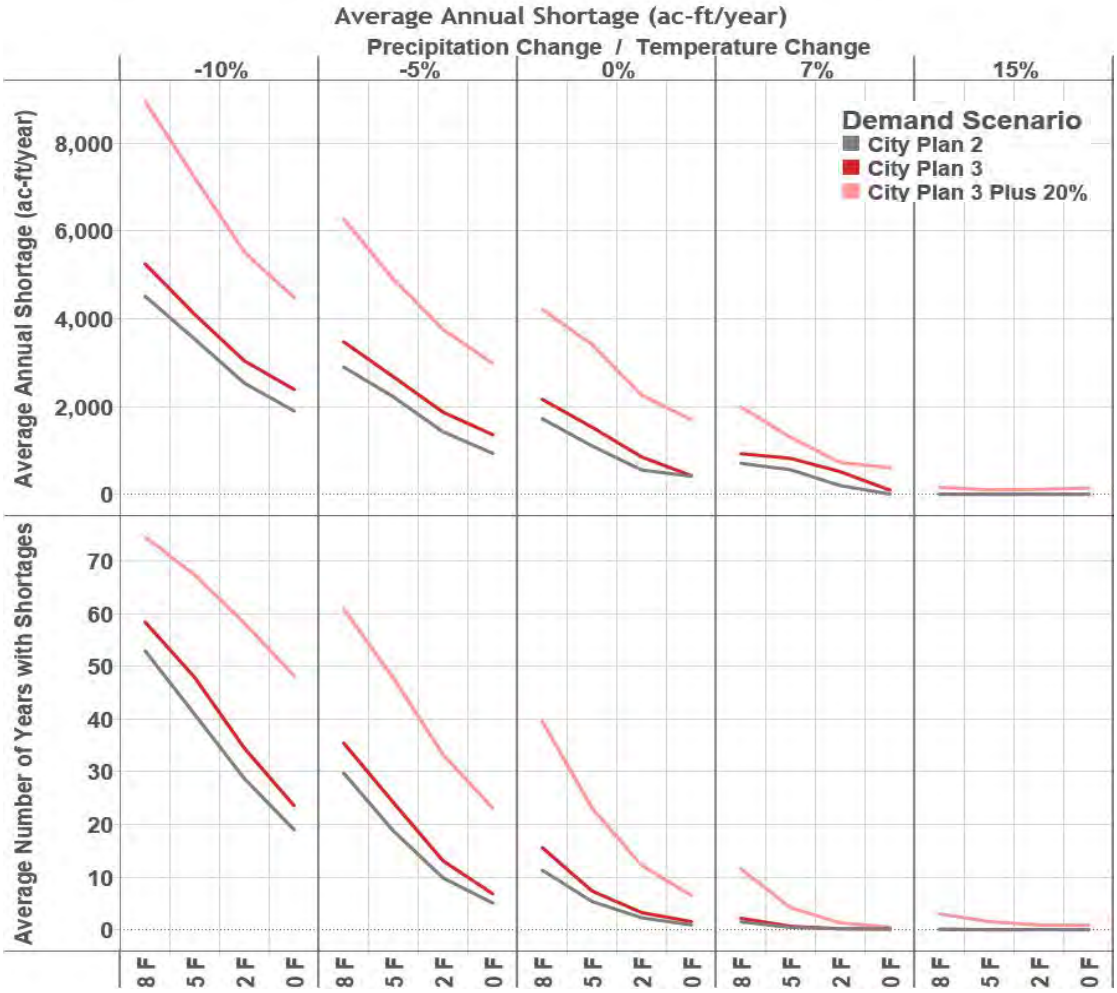

Figure ES-8 Average Annual Total Demand Shortage for Increasing Demand Scenarios and All Climate Conditions

Notes:

a) Poorer performance is indicated by greater shortage volume towards the top of the graph.
b) Current water supply planning policy goal is no shortages for the 1-in-50-year drought.

Besides climate change and increased demands, the risks found to have the largest impact on the Fort Collins system performance relative to the current water supply planning policy criteria are:

- loss of storage, including no Halligan Reservoir enlargement;
- Reuse Plan changes, including elimination or 50% reduction;
- increase in demands above the expected City Plan 3 levels;
- and a long-term reduction in C-BT quota due to constrained C-BT supply or other factors.

Over the four metrics analyzed in this report, those risks and risk scenarios show the poorest performance for current climate conditions and their performance is significantly reduced for the warmer and drier climates.

Figure ES-9 shows the storage reserve metric for all risk scenarios as a function of climate. The storage reserve metric measures the ability to maintain a minimum of 20% of total annual demand in reservoir storage. The water supply policy establishes a level of service of 100% for the storage reserve factor. Under any risk, the FCU system cannot satisfy this LOS goal at most climate futures however the Loss of Storage and No Halligan Enlargement risks have the most significant cumulative impact on maintaining 20% of total annual demand in storage.

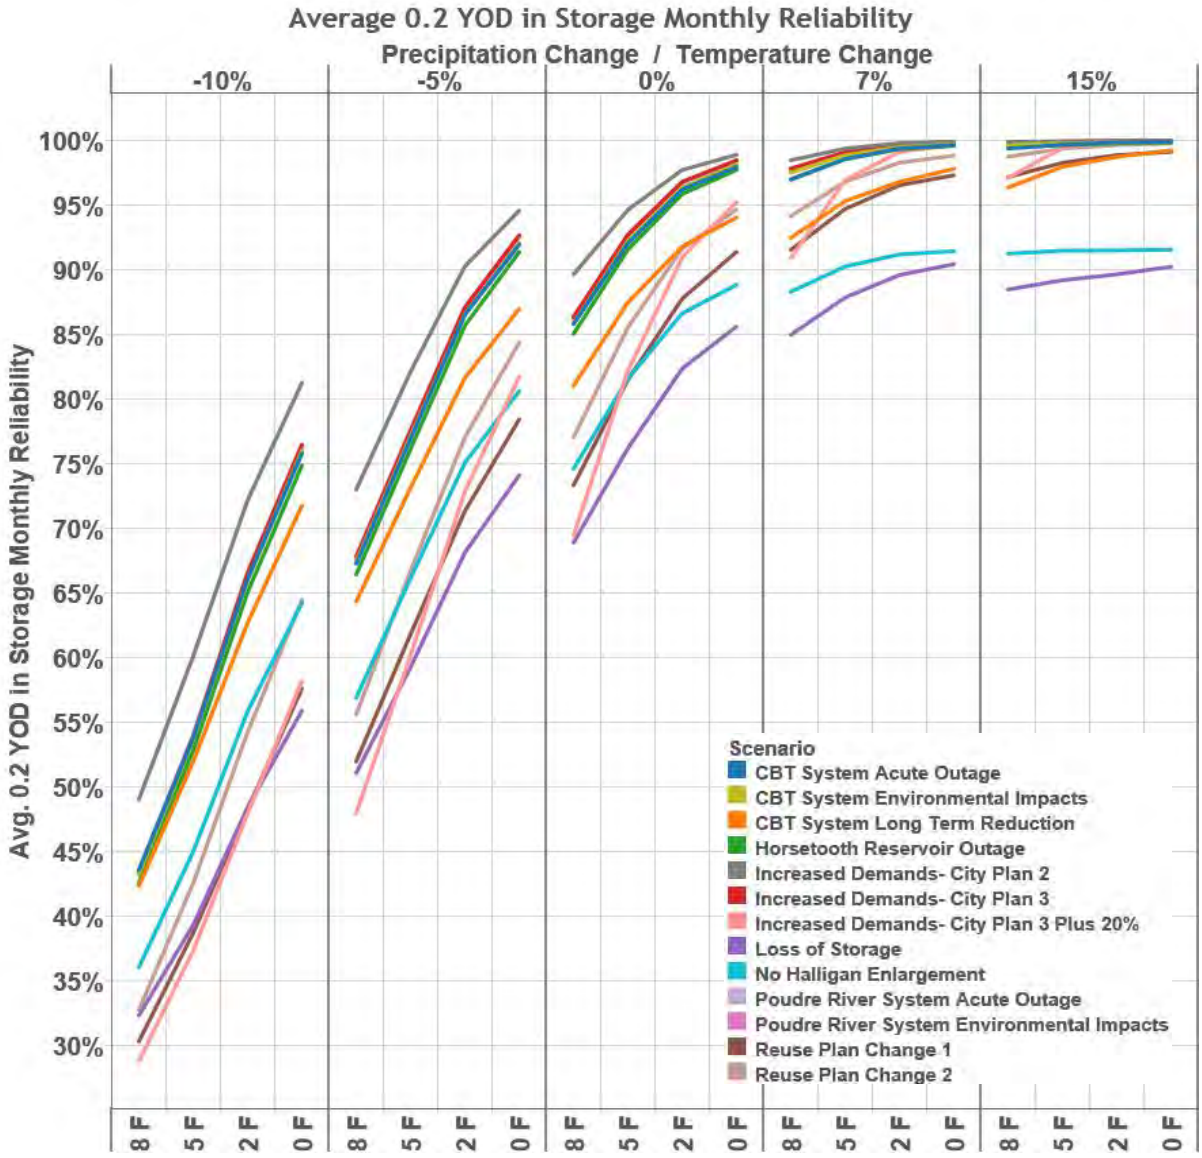

Figure ES-9 Storage Reserve Metric for All Risk Scenarios and All Climate Conditions

Notes:

a) Poorer performance is indicated by lower reliability towards the bottom of the graph.
b) Current FCU policy establishes a goal of 100% for the storage reserve factor during the 1-in-50-year drought.

The risk scenario simulations demonstrated the fundamental difference between long-term or chronic risks and short-term or acute risks. All the most impactful risks based on the metrics used in the WSVS are long-term risks. This is biased by the metrics themselves which, with the exception of the annual demand storage metric, are always calculated over the entire 86-year simulation period. Thus, long-term risks that adversely affect system performance over the entire simulation period or for many years within the simulation period affect metric values more than short-term risks that occur for only a few months or years. Short-term risks such as an outage of the Poudre River pipelines or C-BT facilities can have extreme impacts on system performance for a short period but are masked by climate shifts that cause significant long-term impacts to performance. The effects of long-term risks are not as easily masked by the shifts in climate, as their impacts are also significant over several years or the entire simulation.

Figure ES- 10 highlights the storage reserve metric for the five short-term risks simulated for the WSVS. This figure shows that most of the short-term risk scenarios have very similar performance when measured by the WSVS metrics. Additional investigation may be warranted to develop different metrics that are useful in comparing performance of short-term risks to each other. Many of these short-term risks received relatively high composite scores (likelihood multiplied by impact) at the risk identification workshops, meaning they are of high concern to FCU staff and should be further assessed.

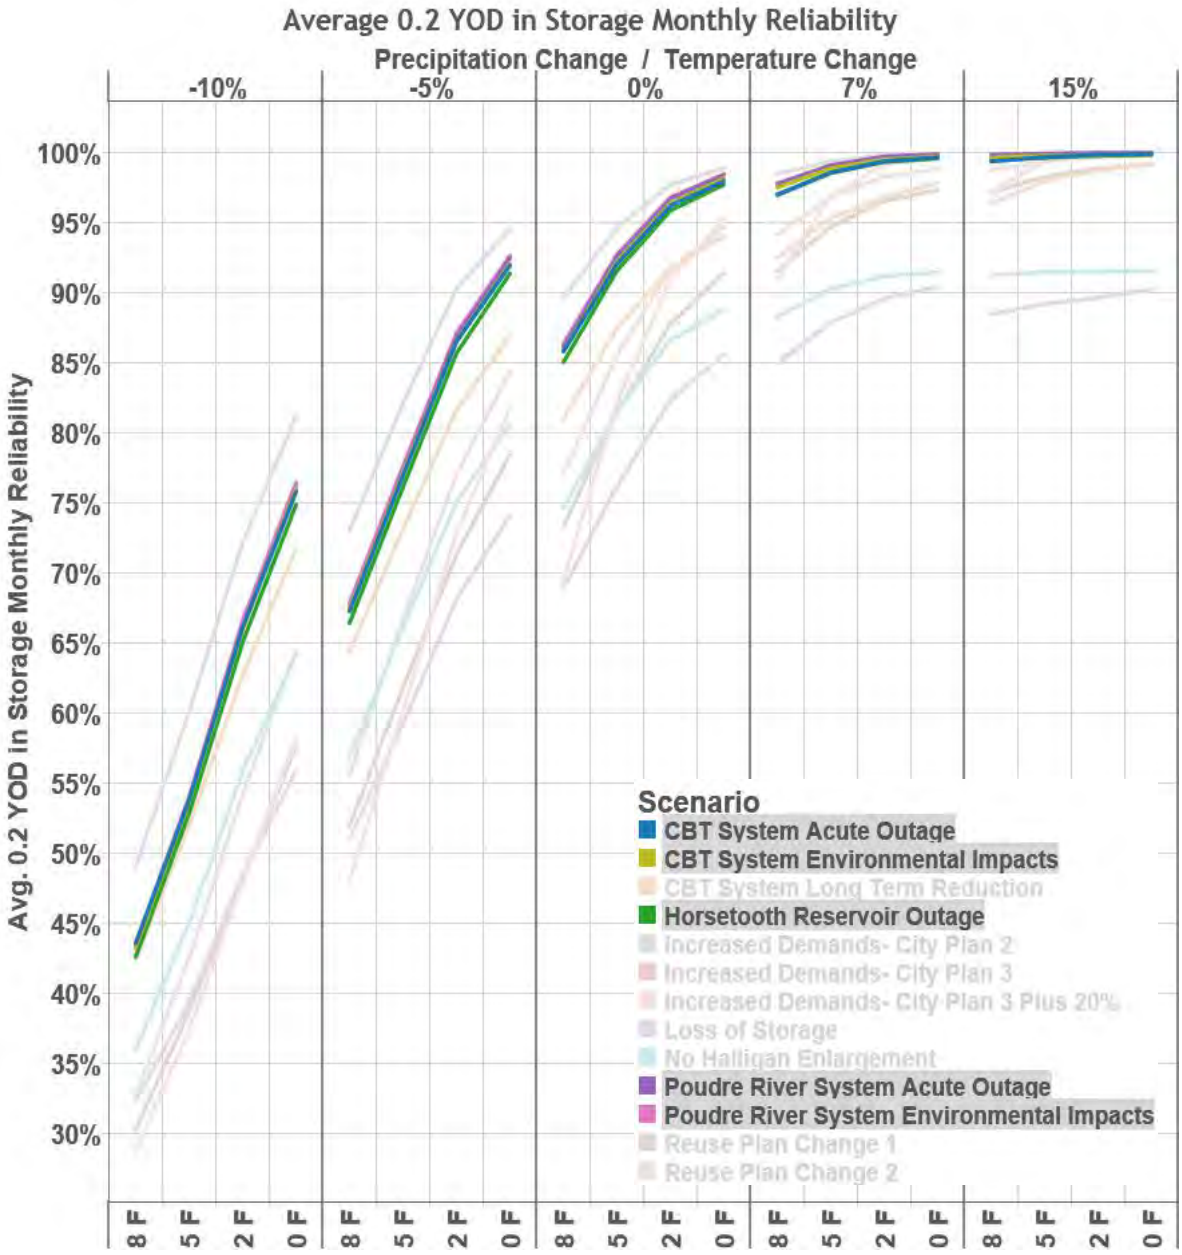

Figure ES- 10 Reliability of Retaining 20% Storage Reserve for Short Term Risks Compared to Long Term Risks

Conclusions

FCU plans to use the results and conclusions of the WSVS as the foundation for updating its Water Supply and Demand Management Policy and its long-range water resources strategy. The following findings from the WSVS may be important as FCU contemplates the coming planning process.

- Climate change is the most important vulnerability faced by the FCU system. Future climate conditions may be more impactful to FCU's ability to meet its water supply planning policy criteria than the occurrence of any particular infrastructure outage or environmental condition simulated by the WSVS risk scenarios. However, climate change is the most difficult risk to track. Long-term trends are difficult to measure and are obscured by the natural variability in wet and dry years. Participating in or keeping informed of state and federal climate change studies will help FCU understand the trajectory of climate change in the region.

- Water demands higher than those forecast in the City Plan 3 scenario represent a significant vulnerability to the current FCU system. This points out the importance of FCU maintaining its water conservation program, and working with City Planning Department to closely monitor population and development density trends to see how they are tracking with City Plan assumptions. An increase in 2070 demands by 20% significantly increases shortages and incidence of failures to meet current water supply policy requiring 20% of average annual demand in storage through a 1-in-50-year drought.

- The risk scenarios found to have the largest impact on the FCU system performance across the range of performance metrics are listed below.

    - Loss of storage, including no Halligan Reservoir enlargement; the FCU system is storage-limited, therefore loss of any existing or proposed storage capacity has significant adverse effects.

    - Reuse Plan changes, including elimination or 50% reduction in the amount of water incorporated in the Plan; the Reuse Plan is a water supply agreement with other Northern Colorado entities that results in additional water supplies for FCU in most years. Losing all or part of the supplies generated from this agreement has compounding effects on FCU water supply.

    - A long-term reduction in C-BT quotas due to C-BT supply or delivery infrastructure issues; C-BT supply is a critical part of FCU's water supply portfolio and reduction in that source over several years significantly impacts FCU's ability to meet its water supply planning policies.

- For most risk scenarios, shortages for climate conditions that are wetter than the current climate would occur most often in late summer and early fall. For warmer and drier climate conditions, shortages would occur throughout the year except in the peak runoff months of May and June. This shows the challenge of maintaining a resilient water resources system in the face of a warmer and drier climate with the limited amount of storage in the FCU raw water system.

- Without the proposed Halligan Reservoir enlargement of 8,125 AF, FCU system performance would be significantly impacted and current water supply planning policy criteria could not be met under most future climate and demand conditions.
- The WSVS highlights the importance of storage in the FCU system and the significant vulnerability posed by the inability to implement the proposed Halligan Reservoir enlargement or a similar storage project as a strategy to mitigate effects of climate change and other risks.
- The WSVS validates that FCU is highly reliant on the C-BT system and is particularly susceptible to extended periods of low quotas and loss of the carryover storage program. FCU should monitor conditions that could trigger either of those risks.
- Results of the WSVS are biased toward long-term risks, but a number of short-term risks were identified that could severely impact FCU operations for a few weeks or months. These conditions will require further study and may involve a different management strategy in the future water supply plan.
- The WSVS analysis was performed without simulating the effects of demand management measures that FCU could adopt under the City's current Water Supply Shortage Response Plan. Investigating benefits of the current shortage response policy should be a key aspect of the water supply plan update.
- FCU now has a water supply modeling tool that can be used to conduct more detailed analyses of the WSVS risk scenarios or explore a broader range of uncertainties or operating conditions if desired. It can also be used to measure and compare the effectiveness of alternative water supply system improvements.

1.0 INTRODUCTION

1.1 PROJECT OBJECTIVES

The objective of the Fort Collins Water Supply Vulnerability Study (WSVS) is to investigate the ability of the Fort Collins water supply system to meet future demands under current policy criteria and level of service goals when subjected to various risks and uncertainties. The WSVS explores and prioritizes the impacts of a wide variety of risks and uncertainties, including:

- hydrologic changes resulting from a warming climate;
- risks of water supply disruptions, such as infrastructure failures;
- wildfires, water quality and other environmental factors; and
- changes in water demands resulting from shifts in population, development density and water use patterns.

The WSVS combines alternative hydrologies, demands, and infrastructure vulnerabilities into plausible scenarios, resulting in a broad range of potential future conditions. Knowledge of these potential futures and the impacts of possible risks and uncertainties on the ability to meet the criteria specified in Fort Collins' current water supply planning policy will allow Fort Collins to determine if its water rights portfolio, raw water infrastructure, and water supply policy and planning efforts are adequate to meet changing water demands into the future.

Results of the WSVS will be used by Fort Collins in the future to investigate potential water resources system improvements and operating policies as part of a planned update to its Water Supply and Demand Management Policy (City of Fort Collins, 2012).

1.2 PROJECT BACKGROUND

1.2.1 Fort Collins Utilities

The City of Fort Collins is located 65 miles north of Denver in Larimer County, between the Rocky Mountains foothills and the Eastern Plains of Colorado. Horsetooth Reservoir borders Fort Collins to the west, the Cache la Poudre River winds its way through north Fort Collins before reaching the South Platte River, east of Greeley and several small gravel pit reservoirs and agricultural reservoirs are located in and around the city.

Fort Collins Utilities (FCU) currently serves about 75% of Fort Collins' residents and businesses. The FCU service area boundary for water, which does not coincide with Fort Collins city limits, is landlocked by neighboring water districts. FCU anticipates little new development and mostly re-development of existing properties within the service area boundary. Fort Collins-Loveland Water District (FCLWD) and East Larimer County Water District (ELCO) provide water to some areas within the city limits and will serve much of the new development in the Fort Collins Growth Management Area ("GMA", or future City limits).

Figure 1-1 shows the spatial extent of the City Limits with respect to the FCU service area, GMA and surrounding water districts.

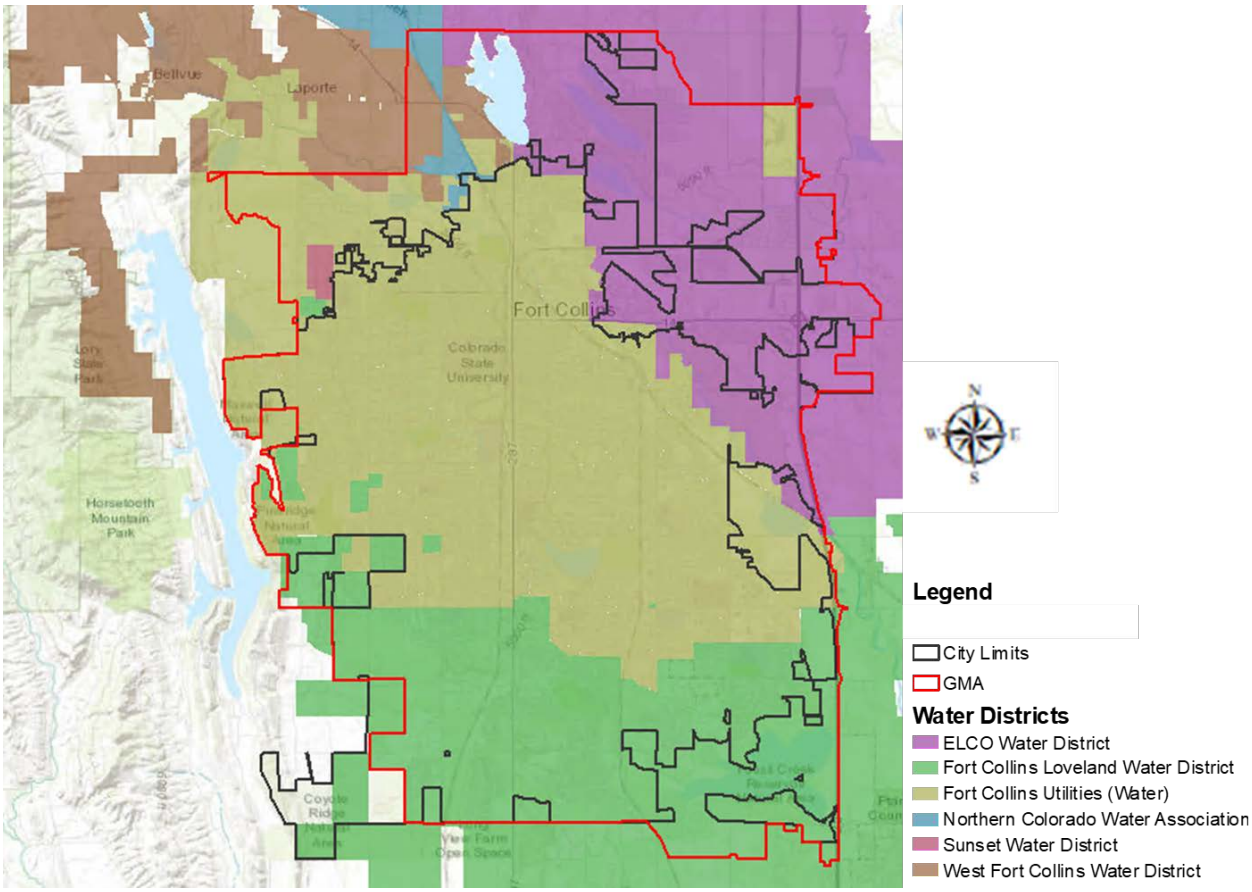

Figure 1-1 Spatial Extent of Fort Collins Utilities Service Area, City Limits and Surrounding Water Districts

FCU supplies an average of about 24,000 acre-feet per year (AFY) of treated water and about 1,100 AFY of raw water to both residential and commercial users with a service area population of approximately 134,300. Additionally, FCU currently has about 3,400 AFY of Colorado-Big Thompson Project obligations, including to City facilities and various Homeowners Associations, as well as agreements with surrounding water districts, municipalities and other entities. Current estimates for the FCU service area show an increase in population to about 178,000 by 2065. Fort Collins is home to Colorado State University and a few large commercial enterprises.

1.2.2 Fort Collins Utilities' Water Supply Sources

FCU's water supply sources come from the Poudre River Basin, the North Platte River Basin (with a transmountain diversion into the Poudre River Basin) and the Colorado-Big Thompson (C-BT) Project, including Horsetooth Reservoir and the Windy Gap Project. FCU's supplies include direct flow rights, converted agricultural rights, C-BT units, supplies from the Michigan Ditch, and storage in Joe Wright

Reservoir and Rigden Reservoir. Key facilities related to delivering water from these sources include two diversion points on the Poudre River, pipelines delivering Poudre River water, Joe Wright Reservoir, the Michigan Ditch, as well as facilities utilized to deliver C-BT and Windy Gap Project water. **Figure 1-2** shows the water supply system for FCU. FCU currently owns limited water supply storage outside of Joe Wright Reservoir. The reservoir, located near Cameron Pass along Colorado State Highway 14, has an active capacity of approximately 7,100 acre-feet. Joe Wright Reservoir is mainly utilized to satisfy current operational and exchange agreements, leaving limited availability for year over year or long-term drought storage. FCU has access to limited carryover storage as part of its ownership in the C-BT system. This storage is not managed by FCU and carries additional costs to utilize. FCU finalized construction and began operation of Rigden Reservoir in 2015. Rigden Reservoir, with an active capacity of 1,900 acre-feet, is located below the FCU wastewater treatment facilities and is not directly tied to treated water operations. Rigden Reservoir is mainly utilized as an operational reservoir to help meet return-flow obligations.

FCU's water supply portfolio contains enough sources to meet demands in most years. However, yields of many of its sources are greatly diminished in dry years, and yields are typically much greater in wet years (some in excess of FCU demands, particularly during the months of high Poudre River flows in May and June). Previous modeling efforts have shown the effect of reliably meeting demands by increasing ownership of water rights is relatively small compared to the effect of increasing system storage capacity due to the uncertainty of the timing of Poudre River flows with respect to the timing of demands.

FCU is currently in the midst of the National Environmental Policy Act (NEPA) permitting process for the enlargement of Halligan Reservoir, an existing reservoir on the North Fork of the Poudre River. The current capacity of Halligan Reservoir is owned and operated by the North Poudre Irrigation Company and cannot be utilized by FCU for water supply storage. Raising the dam will increase Halligan Reservoir's capacity from approximately 6,400 acre-feet to about 14,500 acre-feet and at the same time provide an opportunity to rehabilitate the over 100-year old dam. FCU has various existing water rights to fill the enlarged portion of the reservoir and enlargement would provide an additional 8,100 acre-feet of storage for FCU's use. Previous planning and analyses by FCU staff have determined that enlarging Halligan is a very cost-effective solution to increasing the use of their water rights.

On an annual average basis, FCU receives approximately half of its water supply from the Poudre River and half from the C-BT and/or Windy Gap Projects, which deliver water to Horsetooth Reservoir. FCU works closely with the Northern Colorado Water Conservancy District (Northern Water), which administers the C-BT and Windy Gap Projects, to utilize water supplies out of Horsetooth Reservoir.

FORT COLLINS WATER SUPPLY VULNERABILITY STUDY

INTRODUCTION

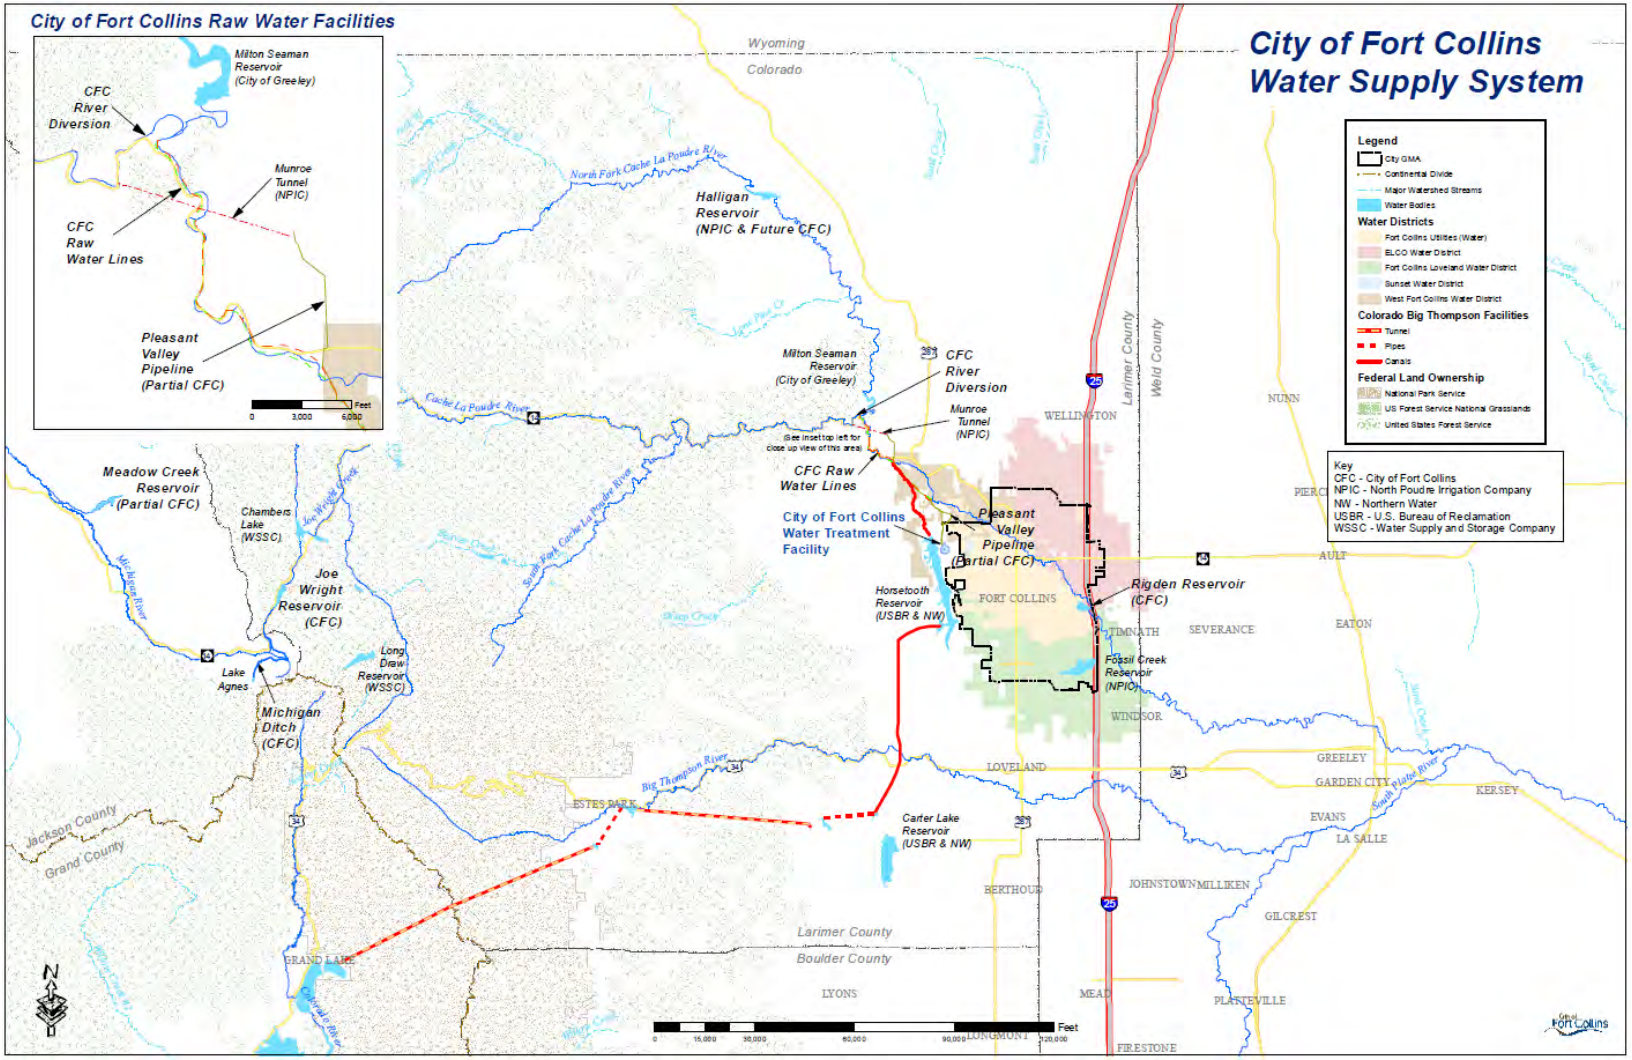

Figure 1-2 City of Fort Collins Water Supply System

1.3 SCOPE OF WORK

The WSVS Scope of Work consisted of the following main tasks.

1. Project Management – Manage scope, schedule and budget and coordinate the project with FCU staff and Northern Water
2. Background and Literature Review – Obtain background information on FCU water supply system and water resources and review applicable literature on climate change and other factors affecting FCU's' water supply reliability
3. Future Water Demand Considerations – Create and apply a Demand Estimation Tool to forecast future water demand, incorporating climate change, population growth and changing land use patterns.
4. Identify Water Supply and Demand Vulnerabilities – Brainstorm and prioritize risks and vulnerabilities that could affect water resources system performance.
5. Develop Potential Yield Changes – Estimate the effect of climate change on hydrology and water rights yield.
6. Scenario Analysis and Framework Development – Create future scenarios comprised of one or more types of risk or uncertainty and assess the performance of the existing water resources system under those scenarios.

1.4 PROJECT AUTHORIZATION

This project was performed by Stantec Consulting Services, Inc. under a contract with the City of Fort Collins. RTI International was a subconsultant to Stantec for hydrologic analyses and demand tool development.

1.5 PROJECT COORDINATION

This project was coordinated closely with FCU staff throughout the project through a series of seven formal workshops, weekly project updates and numerous informal meetings and conference calls.

Northern Water was a partner in the WSVS, providing supplemental funding as well as information and expertise related to its systems. Northern Water staff were included in workshops and project meetings as appropriate.

FCU assembled a Technical Advisory Committee (TAC) consisting of citizens and experts from its Water Resources Board, Colorado State University, and a member representing the surrounding water districts. TAC members were invited to project workshops and received project updates at selected milestones. TAC members included:

- Chris Goemans, Ph.D

- Steve Malers
- Richard Raines

2.0 WATER RESOURCES SYSTEM MODEL

The WSVS involved risk-based water resources planning analyses that required a robust modeling platform to simulate the performance of FCU's raw water system under a wide range of possible future conditions. This section provides a high-level description of the modeling system used to support the WSVS analysis.

The basis of the WSVS modeling system is the water resource modeling platform developed by FCU and other regional water providers in the Poudre River Basin including Northern Water. New modeling tools and improvements to certain model constructs were developed as part of the WSVS project. Most new model development for FCU was performed under Stantec and RTI contracts separate from, but coordinated with, the WSVS study.

2.1 MODELING SYSTEM OVERVIEW

The modeling system used for the WSVS consists of three separate models: the Colorado-Big Thompson Quota Model (CBTQ), the Poudre Basin Network Model (PBN) and the Fort Collins System Model (FCSys). These are run in sequence through a Data Management System (DMS), as shown in **Figure 2-1**. The system is semi-automated and includes the ability to export FCSys output as PBN inputs and vice versa. The models operate on a monthly time-step and each model run simulates a single set of future conditions (water resources system operations and annual demand) for 86 years of variable hydrology.

The three models are described below.

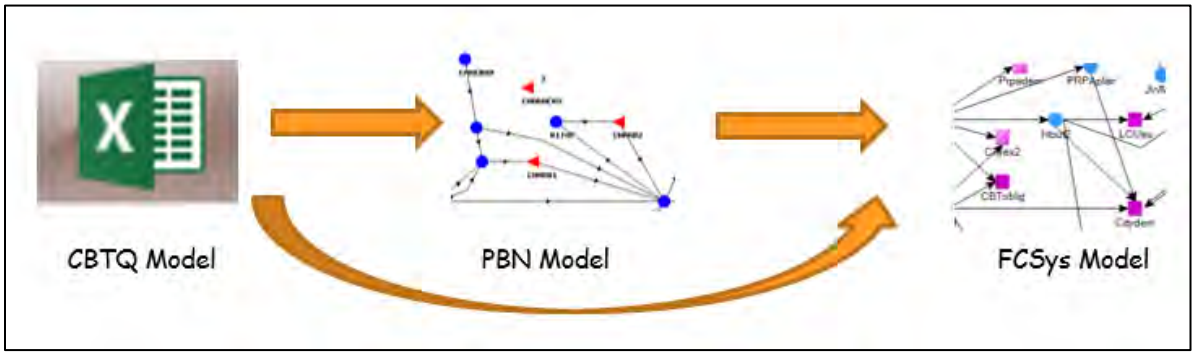

Figure 2-1 FCU Modeling System Overview

2.1.1 CBTQ Model

Northern Water issues allotment contracts for the allocation of Colorado-Big Thompson Project water supplies to water users such as FCU. The allotment contracts call for annual water allocations, known as quotas, to be set by the Northern Water Board based on hydrologic conditions and the needs of its

allottees for supplemental water. Because a significant portion of FCU water supply comes from the C-BT Project, WSVS analyses required an estimate of future C-BT quotas for the conditions being simulated.

The CBTQ Model was developed by Northern Water to estimate annual quotas of C-BT water for its constituents based on hydrology and current operations. The primary function of this model is to determine the C-BT agricultural (Ag) deliveries to the Poudre River for use in the Poudre Basin Network Model (PBN) described below. The CBTQ model is a spreadsheet model and includes native flows of pertinent rivers and creeks on the East Slope and the West Slope that contribute to the C-BT project. Other model inputs include precipitation at the Fort Collins station, starting reservoir storage volumes, initial C-BT M&I ownership and demand, C-BT Ag demand, carryover, influence of the Windy Gap Project and influence of East Slope wildfires. Outputs include annual C-BT quotas, Windy Gap Firming Deliveries and other agricultural ditch deliveries to be imported into the PBN Model. From the C-BT quota, the Fort Collins C-BT allocation can be generated as an input to the FCSys model.

2.1.2 PBN Model

The Poudre Basin Network (PBN) Model is a MODSIM model that simulates water supply infrastructure and operations by municipal, industrial and agricultural entities in the Poudre River basin and the lower South Platte River basin below the Poudre River confluence near Greeley. It was originally developed by Resource Consultants in 1985 for the Fort Collins Drought Study (Resource Consultants, 1985) but has been enhanced by Fort Collins, Northern Water and Greeley over the years to serve a number of purposes. The PBN includes all major water rights within the basin and exchanges operated under their given priority. It also has several special constructs to model system operations such as the routing of transbasin water, return flows and ground water.

The main purpose of the PBN is to quantify yields of agricultural and municipal water rights in the Poudre and South Platte basins. For municipal water providers, the PBN quantifies the potential yield from their water rights for use in their individual system models (such as the Fort Collins System Model described below) for a more refined estimation of current and future water system operations and water use.

Extensive documentation of the PBN model can be found in the Common Technical Platform (CTP) Modeling Report used for the Northern Integrated Supply Project (NISP) environmental impact studies (CDM Smith, 2013). The CTP is also used in the upcoming Halligan Water Supply Project environmental impact studies. Input data selections for the PBN model were the same as the future conditions used for the NISP and Halligan projects environmental permitting analyses.

2.1.3 FCSys Model

The Fort Collins System Model (FCSys) is a MODSIM model developed by FCU that simulates the FCU water supply system under various water demand, water rights, infrastructure and operational scenarios. Output from the PBN model informs the FCSys direct flow water right yields and storage water rights owned by FCU. The FCSys simulates city water deliveries, deliveries to large contractual users (LCU), releases from Joe Wright Reservoir to meet minimum flow requirements under the Joint Operations Plan (JOP) and return flow obligations from the use of converted agricultural water rights. The model also

includes several potential future system components, including additional storage and inflow points for conditional water rights yields.

The FCSys simulates the yield from FCU's shares in several agricultural ditches. These shares are subject to specific terms and conditions, laid out in the change of use decrees. For shares that have not yet been converted to municipal use, certain assumptions have been made regarding future limitations on their use.

As part of the WSVS model upgrades, several improvements were made to the FCSys to more accurately simulate current raw water operations and to remove dependencies of the Excel preprocessing spreadsheet to streamline the automatic simulation of scenarios. Key improvements are described below.

- Simulate the operation of two change of use decrees for the South Side Ditches (SSD), which include New Mercer Canal, Larimer No. 2 Canal and Arthur Ditch, which requires the model to constrain diversions such that they do not exceed the 1-year, 10-year and 30-year running average volumetric limits specified in the decree. The model was revised to include a new side construct and custom code to iterate on the river exchanges such that the water available to meet demand does not exceed the diversion constraints or the exchange potential in the river. The new model also simulates the associated return flow obligations triggered using that water, which is dynamically calculated at run time.

- The FCSys simulates operation of FCU's Reuse Plan. The Reuse Plan is a series of water trades between FCU, Platte River Power Authority (PRPA) and the Water Supply and Storage Company (WSSC). The purpose of the Reuse Plan is to provide 4,200 AFY of reusable (wholly consumable) water produced at the Drake Water Reclamation Facility (DWRF) to the PRPA Rawhide Energy Station. The first use of 6,339 AFY of reusable water, delivered to single-use water customers, results in 4,200 AF of reusable effluent at DWRF that can be piped to the PRPA power plant to fulfill the terms of the Reuse Plan. The upgraded model implements a dynamic representation of the Reuse Plan reducing the water available to meet the City demand if any of the water sources (or combination of sources) fails to have enough water to operate the full Reuse Plan. This implementation allows the model to dynamically simulate water supply operations with a reduced Reuse Plan, making sure that the flexibility to operate the plan is reflected in meeting the requirements and the effects of different water use are carried over to the following years.

- The upgraded model enables simulation of meeting an 800 acre-feet PRPA water demand that is part of the Reuse Plan. This demand can be supplied from storage in Halligan Reservoir, Joe Wright Reservoir, Rigden Reservoir and the SSD return flows. The upgraded model simulates the SGP Reservoir node with a capacity of 1,600 acre-feet. The implementation of this demand links its operation with the Reuse Plan operation, reducing the demand if the full Reuse Plan is not able to be operated.

- The upgraded model implements a new logic for blending water from the Poudre River and Horsetooth Reservoir for water quality purposes at the water treatment plant. The blending logic

controls diversions from the Poudre River to achieve a typical or desired operational mixing ratio between those two sources. This operation supplies the city with a mix of Horsetooth Reservoir and Poudre River supply that is feasible and cost efficient for the City to treat at the current treatment plant while meeting the desired water quality. The logic relaxes the blending constraint in water stress periods when there is not enough water in either of the sources to supply the full demand, i.e., the logic uses the available water in water stress situations to avoid causing additional water shortages.

2.1.4 Data Management System

The modeling framework used for the WSVS consists of a new Data Management System (DMS). As shown in **Figure 2-2**, the DMS structure has three major components: the Structure Query Language (SQL) server database (in which model inputs such as hydrology, demand and system risks and output metrics are stored), the simulation model system and the DMS program (code) itself. User defined model settings are entered into the DMS which extracts the desired model inputs and scenario information from the database and translates them into raw input files for the CBTQ, PBN and FCSys models. The models are then run with these settings, in sequence, and the DMS calculates and extracts the output metrics. The results stored in the database can be accessed by external visualization software such as Tableau for further analysis.

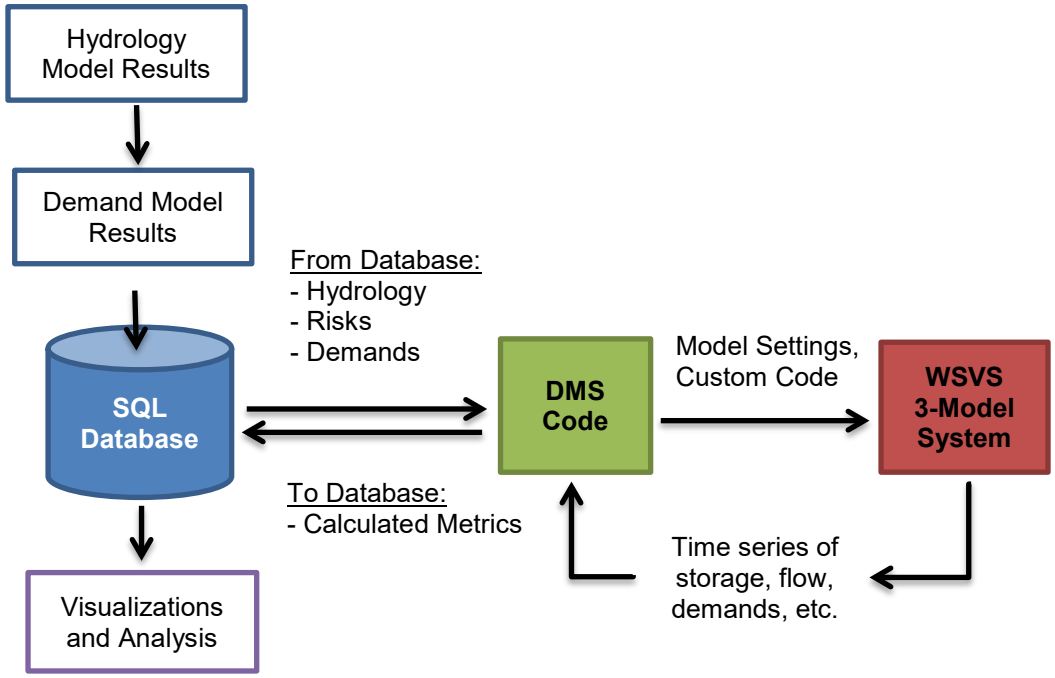

Figure 2-2 WSVS Data Management System

2.1.5 Comparison of WSVS Modeling System to Previous Models

Fort Collins has used previous versions of the PBN and FCSys models for past water resources planning and decision-making. Other agencies such as Northern Water and Greeley have used previous versions of the PBN model for their planning. For example, the Halligan Water Supply Project Environmental Impact Study (EIS) and the Northern Integrated Supply Project EIS used previous versions of the PBN and FCU's system models in a Common Technical Platform (CTP) to size the respective water supply projects and EIS alternatives and assess their hydrologic impacts in the Poudre River Basin. For the WSVS, analyses including an enlarged Halligan Reservoir were all based on the size of the enlargement developed from the CTP and used in the EIS studies.

The Halligan Project EIS modeling and the WSVS modeling are distinct modeling efforts that have been conducted for separate purposes. The WSVS modeling system was not developed to re-evaluate the proposed sizing of the Halligan Water Supply Project, and it does not simulate flows in streams that could be affected by water development projects in the Poudre River basin. Rather, the modeling system modifications made as part of the WSVS were necessary to give FCU the ability to assess future risks to the performance of its water resources system. Previous versions of the modeling system were not capable of simulating risks to the system such as climate variability, environmental risks and infrastructure outages, or of running and tracking many different scenarios simultaneously. In addition, the previous modeling system was not set up to calculate measures of system performance such as reliability and resilience that FCU wants to use in future water supply planning studies. These modeling system improvements were required as part of the WSVS to identify and prioritize future risks for which FCU should be planning with or without the proposed enlargement of Halligan Reservoir.

2.2 METRICS AND LEVEL OF SERVICE GOALS

This section summarizes the development of metrics and level of service goals that were necessary to measure and assess the performance of the FCU water resources system under simulated risks and uncertainties. More detail is provided in the Level of Service Goals and Metrics Technical Memorandum (Stantec, 2018a), included in Appendix A.

The WSVS used the FCU modeling system to evaluate FCU water supply system performance. "System performance" is defined as the ability to meet customer demands and satisfy adopted water supply planning policy criteria. For FCU, the current policy establishes an objective of:

- meeting demands calculated using a per capita use factor of 150 gallons per capita per day,
- through the 1-in-50-year drought,
- with no shortages or water restrictions,
- while maintaining a minimum of 20 percent of annual demand in reservoir storage at all times (storage reserve factor).

As part of the WSVS, the performance of the FCU water supply system was quantified using measurable parameters (metrics) with target values based on the water supply policy criteria (level of service goals). The performance metrics and level of service goals were identified and calculated as part of the modeling system outputs.

Performance metrics and level of service goals, needed to quantify satisfactory and unsatisfactory water supply system performance, are further defined as follows.

Performance Metrics are specific measures characterizing the key features of a water supply system that are definable, measurable, representative and unique. Performance metrics are traditionally presented using the terms reliability, resilience and vulnerability (RRV) but can also be calculated using statistical measures such as the mean, median, maximum, or minimum. The formal definitions of reliability, resilience and vulnerability are:

- *Reliability* is the probability that the water supply system feature is in a satisfactory state, answering the question “how often”.
- *Resilience* is the probability that a time period when the water supply system feature is in an unsatisfactory state is followed by a time period when the water supply system feature is in the satisfactory state, answering the question “how long”.
- *Vulnerability* is the severity or magnitude of the unsatisfactory state for the water supply system feature, answering the question “how severe”.

Other examples of performance metrics could be maintaining a minimum volume of water in storage in July, years without customer restrictions, or a target for use of C-BT supplies.

Level of Service (LOS) goals are thresholds used to separate key performance metrics into satisfactory and unsatisfactory states. Examples of level of service goals could be triggering customer watering restrictions 5% of the time or maintaining a volume of water equivalent to 1 year of demand in storage in April in 90% of years.

Performance metrics were identified during a workshop conducted with FCU staff and were tied to the current water supply planning policy criteria. **Table 2-1** lists the identified performance metrics for the FCU water supply system that were used for the WSVS.

Table 2-1 Identified Performance Metrics

	ID	Performance Metric	Description
Meeting Customer	1	Minimum Met Annual Demand	The minimum annual demand met in acre-ft/year across a simulation
	2	Meeting Indoor Demands	The RRV[3] of meeting indoor demands across a simulation
	3	Meeting Reduced Demands	The RRV[3] of meeting demands after they have been reduced by restrictions

FORT COLLINS WATER SUPPLY VULNERABILITY STUDY

WATER RESOURCES SYSTEM MODEL

	ID	Performance Metric	Description
	4	Annual Response Level 1 Restrictions[1]	The R&R[2] of when customers are in Response Level 1 restrictions across a simulation
	5	Annual Response Level 2 Restrictions[1]	The R&R[2] of when customers are in Response Level 2 restrictions across a simulation
	6	Annual Response Level 3 Restrictions[1]	The R&R[2] of when customers are in Response Level 3 restrictions across a simulation
	7	Annual Response Level 4 Restrictions[1]	The R&R[2] of when customers are in Response Level 4 restrictions across a simulation
Maintaining Supply in Storage	**8**	0.1-Year of Demand in System Storage	The RRV[3] of maintaining 0.1-Year of Demand in Storage at all times during a simulation
	9	0.2-Year of Demand in System Storage	The RRV[3] of maintaining 0.2-Year of Demand in Storage at all times during a simulation
	10	0.3-Year of Demand in System Storage	The RRV[3] of maintaining 0.3-Year of Demand in Storage at all times during a simulation
	11	0.4 Year of Demand in System Storage	The RRV[3] of maintaining 0.4-Year of Demand in Storage at all times during a simulation
	12	0.5 Year of Demand in System Storage	The RRV[3] of maintaining 0.5-Year of Demand in Storage at all times during a simulation
	13	0.6 Year of Demand in System Storage	The RRV[3] of maintaining 0.6-Year of Demand in Storage at all times during a simulation
	14	0.7 Year of Demand in System Storage	The RRV[3] of maintaining 0.7-Year of Demand in Storage at all times during a simulation
	15	0.8 Year of Demand in System Storage	The RRV[3] of maintaining 0.8-Year of Demand in Storage at all times during a simulation
	16	0.9 Year of Demand in System Storage	The RRV[3] of maintaining 0.9-Year of Demand in Storage at all times during a simulation
	17	1.0 Year of Demand in System Storage	The RRV[3] of maintaining 1.0-Year of Demand in Storage at all times during a simulation
	18	Minimum Storage – Year of Demand	Minimum Year of Demand storage volume during a simulation
	19	Minimum Storage – acre-feet	Minimum acre-foot storage volume during a simulation
Operational	**20**	Lost Water Due to Water Quality Requirement	Statistical quantifications (average, max, count) of annual volume of water lost due to water quality blending requirements
	21	Lost Water Due to Insufficient Storage	Statistical quantifications (average, max, count) of annual volume of useable water lost due to insufficient storage capacity
	22	Meeting Reusable Demands	The RRV[3] of meeting reusable demands

Notes:
1) As defined in the Water Supply Shortage Response Plan (City of Fort Collins, 2014)
2) R&R is Reliability and Resilience
3) RRV is Reliability, Resilience and Vulnerability

The performance metrics were evaluated to determine which are applicable as level of service goals and what the thresholds for level of service are. Seven performance metrics were included as level of service goals, which are shown in **Table 2-2**. Level of service goals were selected to align with FCU's water supply planning policy criteria.

The selected level service goals are primarily customer-facing, such that futures that significantly impact customers based on the current water supply policy will be considered unsatisfactory. These are defined briefly below.

- Any future for which indoor demands are not always met (100% reliability) will be unsatisfactory.
- The current water supply policy sets a goal of meeting all demands during the 1-in-50 year drought without water restrictions. However, based on recent experience, FCU accepts future conditions in which any type of water restriction is declared as often as every 1 in 10 years (90% reliability) with more impactful water restrictions occurring less frequently.
- To comply with the current water supply policy, at least 20% of annual demand must be maintained in storage at all times for a future to be considered satisfactory. This is referred to as the Storage Reserve Factor.
- Finally, all reusable demands must be met 100% of the time.

Table 2-2 Selected Level of Service Goals

ID	Performance Metric	Level of Service Goal	Justification
2	Meeting Indoor Demands	100% Reliability	Greatest customer impact
4	Annual Response Level 1 Restrictions[1]	1 in 10 Years (90% Reliability)	Perceived customer risk tolerance
5	Annual Response Level 2 Restrictions[1]	1 in 25 Years (96% Reliability)	Perceived customer risk tolerance
6	Annual Response Level 3 Restrictions[1]	1 in 100 Years (99% Reliability)	Perceived customer risk tolerance
7	Annual Response Level 4 Restrictions[1]	1 in 500 Years (99.8% Reliability)	Perceived customer risk tolerance
9	0.2-Year of Demand in System Storage	100% Reliability	Governing policy
20	Meeting Reusable Demands	100% Reliability	Reuse Plan Agreement

[1]**As defined in the Water Supply Shortage Response Plan (City of Fort Collins, 2014)**

These LOS goals were used in the WSVS to separate futures for which water supply system performance is satisfactory from those for which it is unsatisfactory. However, these LOS goals are a policy decision, and one potential water resources strategy is to change the LOS goals or thresholds to take on more risk. For example, FCU could lower the storage requirement from 0.2 to 0.1 years of demand in storage with 100% reliability, thereby improving performance (relative to the relaxed objective) but increasing the risk

that sufficient water would not be available during an emergency. This question will be addressed as part of a future study to update the FCU Water Supply and Demand Management Policy.

3.0 HYDROLOGY

A primary input to the WSVS analysis was future inflows to the FCU water supply system. Because an objective of the WSVS was to investigate the impact of hydrologic uncertainty on the FCU system, estimating future inflows for water supply planning required a hydrologic analysis incorporating uncertainty in the timing and magnitude of future surface water supplies. Hydrologic uncertainty could be due to greater interannual variability than is present in the historical record or to long-term climate change.

This section summarizes the process used to develop 100 potential hydrologic sequences based on the same statistics as the historical hydrologic record but incorporating more variability and the adjustment of those sequences to incorporate potential future climate change. The process used to generate potential future hydrologies is described in two technical memoranda – Future Hydrologic Analysis Technical Memorandum (RTI, 2018) and Hydrologic Modeling Approach Technical Memorandum (RTI, 2018b) in Appendix D and in Appendix E.

3.1 HYDROLOGIC MODELING APPROACH

Synthetic sets of potential future hydrologic inputs that include variability and large-scale shifts in precipitation and temperature trends due to potential climate change were generated for use in the Fort Collins Modeling System. These datasets capture more natural variability and more climate effects than the historical observed streamflow record, and thus, represent sets of different potential conditions in the basin. **Figure 3-1** provides an overview of the process used to generate hydrologic datasets for the WSVS.

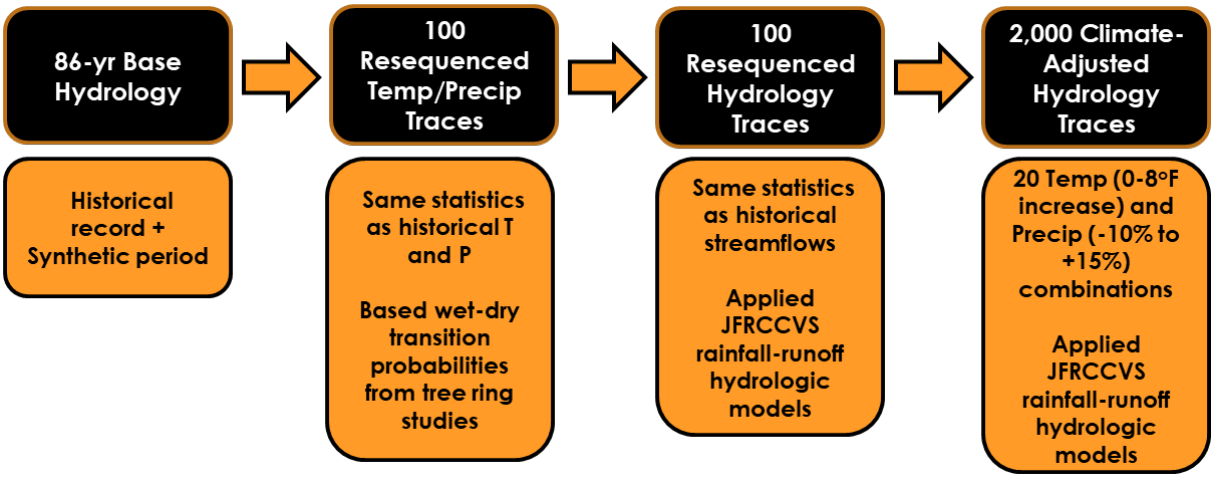

Figure 3-1 Overview of Hydrologic Analysis Process
Note: JVRCCVS = Joint Front Range Climate Change Vulnerability Study

FORT COLLINS WATER SUPPLY VULNERABILITY STUDY

HYDROLOGY

To construct the WSVS hydrology datasets, 100 sets of 86-year long monthly precipitation and temperature data sequences were developed based on wet to dry year transition probabilities seen in an ensemble of reconstructed flows for the Cache la Poudre River at Canyon Mouth (Woodhouse, 2006). These traces of “weather” were then used to generate 100 streamflow traces using the Joint Front Range Climate Change Vulnerability Study (JFRCCVS) hydrologic models. These synthetic traces are similar to historical streamflow but with potentially longer dry periods or more variable transitions from wet to dry periods.

Next, each trace was climate adjusted based on 20 combinations of temperature and precipitation changes from historical conditions. The temperature and precipitation offsets were based on the range of future conditions forecast by commonly used Global Climate Models (GCMs). A range of published results for the CMIP 5 (Coupled Model Intercomparison Project Phase 5), 4.5 and 8.5 emission scenario GCM models in the Poudre River watershed are shown in **Figure 3-2**. In emission scenario 4.5, greenhouse gas emissions peak around 2040, then decline. In emission scenario 8.5, greenhouse gas emissions continue to rise throughout the 21st century.

The figure shows dots at pairs of simulated change in average temperature and precipitation from 1981-2010 to 2050-2074, for each GCM model and for each emission scenario, in relation to the selected temperature and precipitation changes selected for this study (i.e., shown by the triangles). In general, GCMs consistently show that future climate in the Poudre River watershed will be warmer, but they are not consistent in predictions about the direction of change in future precipitation. Similar findings apply to GCMs in the Upper Colorado River watershed that supplies the C-BT Project. The WSVS is concerned with hydrologic conditions that would stress the FCU water supply system, so 20 T/P combinations were selected ranging from 0 to 8 degrees Fahrenheit warmer and -10% to +15% wetter. The National Climate Change Viewer from USGS indicates precipitation changes from -6% to +31%, and temperature increases from 0.6 °C to 4.9°C for the Poudre basin across the different GCMs for the 2050-2074 period (Alder and Hostetler, 2013). If studies were to look further into the future, changes would likely continue to increase. While some GCMs indicate that precipitation may increase more than 15%, FCU does not expect larger precipitation increases to be a source of vulnerability. The result of the climate change review was selection of 2,000 (100 x 20) climate altered hydrologic sequences that could be used to test the impact of future climate on FCU system performance.

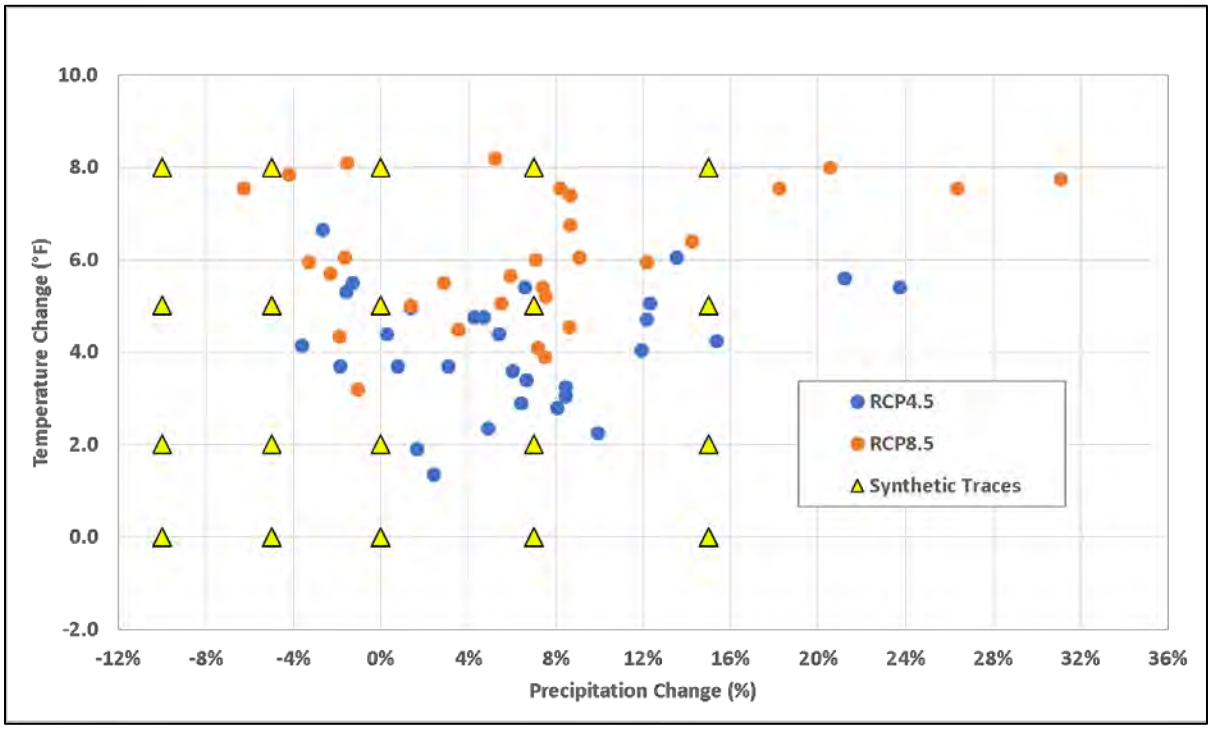

Figure 3-2 Temperature and Precipitation Combinations Used for Climate Change Hydrology Compared to Range of Selected GCMs

Note: GCM results represent the simulated increase in temperature and precipitation projected by the CMIP 5 models with emission scenarios 4.5 and 8.5. The increase in temperature and precipitation is calculated as the increase of the average simulated values for the period between 2050 and 2074 conditions, compared with the average for the period 1981-2010.

3.2 HYDROLOGIC RESULTS

The hydrology results described above capture more natural variability and more climate effects than the historical observed streamflow record; and thus, represent sets of different potential conditions in the basin. Reconstructed input data for the model were based on the sum of flows at the Cache la Poudre River at Canyon Mouth and the Colorado River at Granby Lake. **Figure 3-3** shows annual average flows for about 20 of the constructed flow traces without climate adjustments for the Cache La Poudre at Canyon Mouth and the Lake Granby gage locations. The blue line is the historically modeled flows from which the other traces were developed. As seen, there is significant year-to-year variability. The randomly chosen subset of constructed flows range from a minimum of around 50,700 AFY to a maximum of 687,800 AFY for the Cache La Poudre gage and from 79,600 AFY to 629,900 AFY for the Granby gage. The baseline trace for the Cache La Poudre gage has comparable overall annual averages between 50,700 AFY and 579,200 AFY and the baseline trace for the Granby gage has an overall average annual flow between 108,600 AFY and 514,000 AFY.

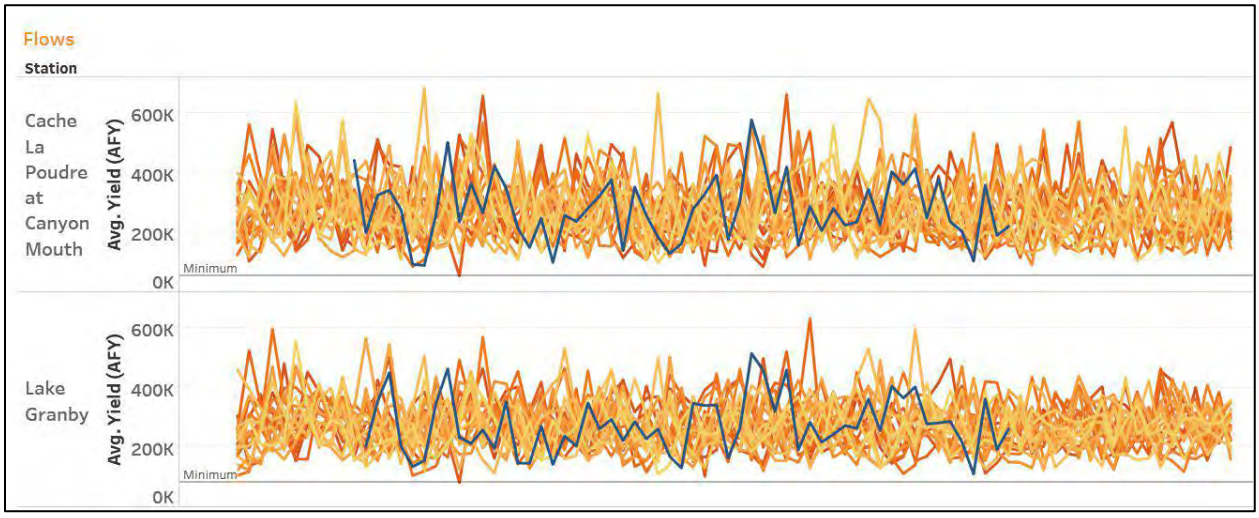

Figure 3-3 Average Annual Synthetic Flow Traces Without Climate Adjustment for the Cache la Poudre at Canyon Mouth and Lake Granby Gages

Naturalized streamflows for 11 inflow points in the PBN model that represent water availability were generated from these 2,000 new hydrology sets. The simulated naturalized flows are the source of the main hydrology inputs for the PBN model. A few PBN constructs such as the excess precipitation construct, agricultural demands and the trans-basin diversions were identified as needing an approach that would synchronize those inputs with the same future hydrologic conditions. The selected approach was based on the like-year method, used in previous PBN analyses for estimating these PBN input time series for future conditions. The like-year method determines values for the new time series based on values from a historical year with the most similar total annual flows at key locations. For consistency, all PBN model input time-series, except the generated 11 naturalized stream flows, used a like-year approach to simulate future conditions.

The synthetic naturalized flow datasets had both wetter and drier periods of flow than the historical base flow dataset. These flows also had, for some climates, an earlier shift in peak runoff. **Figure 3-4** shows an example of the peak runoff shifting from June in the no climate change condition to May in the two warmest climate conditions. Simulating these changes in the models through the synthetic hydrologic inputs incorporate identified risks by both FCU and Northern Water surrounding changes in runoff timing.

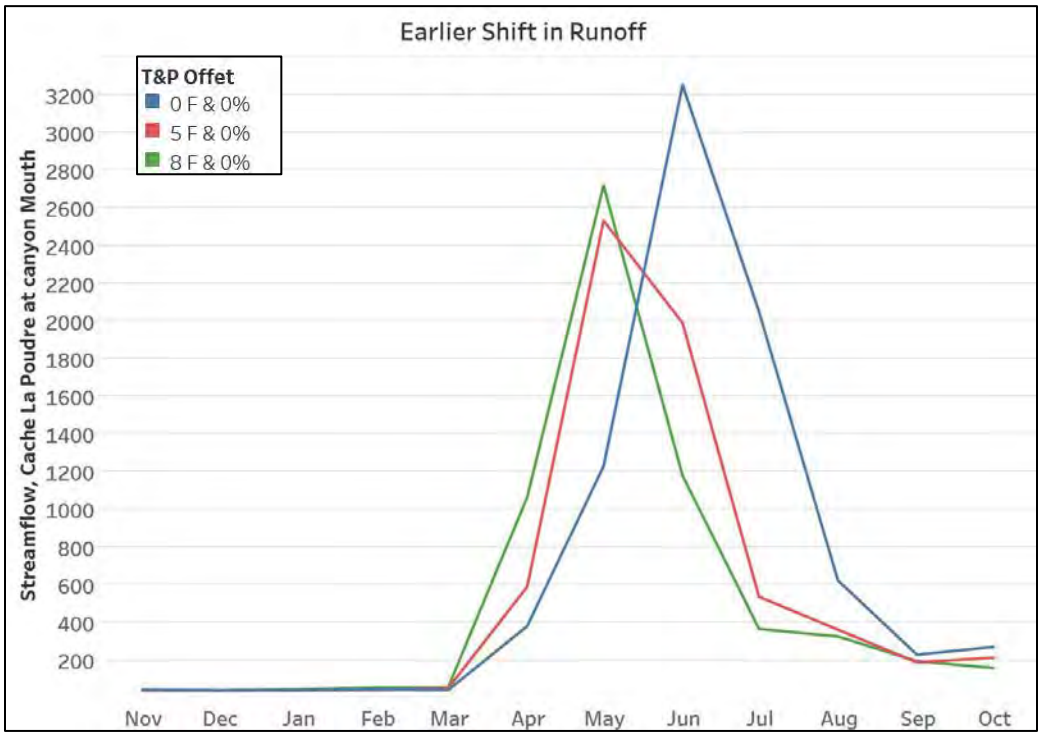

Figure 3-4 Streamflow for Selected Trace Depicting a Shift to Earlier Runoff for Warmer Climates

Figure 3-5 shows the average of the annual flows for all 100 traces for each of the 20 climate combinations for both the Poudre River at Canyon Mouth naturalized flows and the Lake Granby naturalized flows. Average annual streamflow volumes amongst the traces for the Poudre River at Canyon Mouth range from 70% of baseline flow (i.e., the flow based on historical temperature and precipitation, or delta T = 0 and delta P = 0) for the hottest, driest traces to 139% of baseline flow for the coolest, wettest traces. Flow changes at Granby were comparable. For comparison, under a plausible future climate that is 5 degrees F warmer than historical with the same average annual precipitation, the simulated average annual streamflow at the Poudre River at Canyon Mouth gage is 21,000 AFY (8%) less than historical.

		Delta P				
Basin	Delta T	-10%	-5%	0%	7%	15%

	0 F	81% 218,725	90% 244,938	100% 270,981	113% 306,969	128% 347,893

Figure 3-5 Average Annual Flow Volume for Hydrologic Traces

Note: Each cell shows the mean of the average annual flows for the 100 traces with the corresponding T/P combination expressed in AFY and as a percentage of the average annual flow for the T=0, P=0 combination.

In recent water supply planning studies, including the Halligan Water Supply Project EIS, FCU has used a single 86-year hydrologic record that is a combination of historical data and a statistically developed synthetic period. The synthetic period includes the statistically developed 1-in-50-year critical drought used for previous planning studies and defined in FCU's water supply planning policy. The critical drought period has a 6-year duration with an average annual flow at the mouth of the canyon of 196,090 acre-feet. In order to compare that 6-year critical period with the most severe 6-year droughts in the synthetic hydrologic traces developed for this study, the minimum 6-year rolling average annual flow volumes were computed for each of the 2,000 hydrologic scenarios. This provides a proxy for comparing the 1-in-50-year drought used for past planning with the relative severity of the 6-year critical periods embedded in the WSVS synthetic hydrology.

Figure 3-6 shows the average magnitude of the minimum 6-year rolling average flow for the 100 traces in each of the 20 climate change combinations for the Cache La Poudre at Canyon Mouth gage, and also reports this value as a percentage of the 196,090 acre-feet annual flow used as the critical drought in past planning studies by FCU. The 100 hydrologic traces in the WSVS hydrologic dataset for the unaltered historical climate conditions (T=0, P=0%) have an average 6-year critical period flow at this location of 191,343 AFY, which is a 2% reduction from the historical critical drought period. The hottest/driest climate condition (T=+8, P=-10%) produces an average 6-year critical period annual streamflow that is 31% less than the critical period streamflow currently used for planning. The coolest/wettest climate condition (T=0, P=+15%) produces an average 6-year critical period annual streamflow that is 38% more than the critical period streamflow currently used for planning.

Basin	Delta T	Delta P -10%	-5%	0%	7%	15%
Cache La Poudre at Canyon Mouth	8 F	69% 134,494	79% 154,857	90% 175,760	105% 206,438	124% 242,757
	5 F	71% 138,641	82% 160,128	93% 182,329	109% 214,181	129% 252,189
	2 F	72% 141,549	84% 164,188	96% 187,637	113% 222,273	134% 262,657
	0 F	74% 144,201	85% 167,066	98% 191,343	116% 227,311	138% 270,817

Figure 3-6 Minimum 6-year Average Annual Flow Volume for Climate Altered Hydrologic Traces in Acre-Feet per Year and as a Percentage of Hydrologic Traces Based on Historical Climate - Cache La Poudre at Canyon Mouth gage

Notes:

a) Each cell presents values based on the average of 100 traces for the pertinent climate condition.
b) The lower value in each cell is calculated from the lowest 6-year moving average value in the 86-year synthetic streamflow traces.
c) The upper value in each cell is the minimum 6-year moving average flow volume for that climate condition expressed as a percentage of the minimum 6-year moving average flow volume from the FCU planning hydrology.

Figure 3-7 shows the percentage of the 100 traces for each of the 20 climate adjustments at the Cache La Poudre at Canyon Mouth gage that capture at least one 6-year critical drought period that is worse than the critical planning drought from the current FCU hydrologic planning timeseries. The figure illustrates the minimum 6-year average flow in a synthetic 86-year hydrologic trace is very sensitive to average annual precipitation. A 5% decrease in average annual precipitation forces essentially all traces to have at least one 6-year critical period with less average streamflow than in the critical period currently used by FCU for water supply planning. Conversely, a 15% increase in average annual precipitation forces essentially all traces to have no 6-year critical periods with less streamflow than in the critical period currently used by FCU for water supply planning.

		Delta P				
Basin	Delta T	-10%	-5%	0%	7%	15%
Cache La Poudre at Canyon Mouth	8 F	100%	100%	89%	26%	2%
	5 F	100%	100%	80%	15%	1%
	2 F	100%	99%	64%	11%	1%
	0 F	100%	99%	55%	7%	0%

Figure 3-7 Percent of Hydrologic Traces with a Minimum 6-year Average Annual Flow Volume at Cache La Poudre at Canyon Mouth Gage Less Than Critical Planning Drought

These characteristics of the WSVS hydrology are important when interpreting the vulnerability study results relative to water supply policy criteria that are based on the 6-year duration, 1-in-50-year drought in the runoff data currently used for planning. The minimum 6-year moving average flow analysis demonstrates that the 1-in-50-year drought upon which the current water supply policy is based is highly sensitive to assumed climate conditions. This explains the sensitivity of system performance metrics based on the water supply policy to future climate variability, as described in Section 7.3.

4.0 WATER DEMANDS

Future water demand is a significant uncertainty to be evaluated in the WSVS. Water demand is a function of population, development density, success of water conservation measures, technology in water fixtures and irrigation systems, economic conditions and other factors that are difficult to predict. In addition, demand varies year to year based on weather conditions during the landscape irrigation season. As a result, the WSVS required a method for estimating future water demands under a range of assumed future conditions.

Future water demands for the FCU service area were estimated using a new Demand Estimation Tool developed for this project. Development of the Demand Estimation Tool is described in the Water Demand Forecasting Tool Technical Memorandum (RTI, 2019) contained in Appendix C. This section provides a brief description of the Demand Estimation Tool and the demand forecasts developed for use in the WSVS.

4.1 DEMAND FORECASTING TOOL

The Fort Collins Demand Estimation Tool incorporates the variables and computational algorithms used in the demand forecasting model, which was developed based on input by FCU staff and implemented by RTI. The demand model consists of individual linear regression models, each developed for the following groups of water customers: single family and duplex, multifamily, commercial small, commercial medium and commercial large customers. It was developed using processed historical customer-level water use data from 2001-2016 to estimate future water demand at a monthly time step. The independent variables used in the model to estimate water use under different future conditions are listed in **Table 4-1**. Not all independent variables were used to estimate water demand for all the customer groups.

Table 4-1 Independent Variables Used in the Regression Equations in the Demand Estimation Tool

Variable Name	Description
(Intercept)	Equation constant
daysover85	Numbers of days in the month with the max temp over 85
irrig_rain_mon	Total rain in the month, only for May through September, equals zero for the other months
summer	Equals 1 if May through Sept
bed	Number of bedrooms
units	Numbers of units
unemprate	Unemployment rate (monthly)
parcel_acr_CLg	Parcel size, acres for large commercial
parcel_acr_CMd	Parcel size, acres for medium commercial
parcel_acr_CSm	Parcel size, acres for small commercial
parcel_acr_MF	Parcel size, acres for multi-family parcels

Variable Name	Description
parcel_acr_SMDUP	Parcel size, acres for single family and duplex parcels
commindust	Equals 1 if primarily an industrial or commercial zone
downtown	Equals 1 if primarily a downtown zone
harmish	Equals 1 if primarily a harmony corridor or employment zone
residential	Equals 1 if primarily a residential zone
retail	Equals 1 if primarily a retail zone

The Demand Estimation Tool estimates future water demand using the demand regression models to predict the average water use, per premise, by month for each of the five water user types. Because water demand is estimated as a function of weather variables such as monthly rainfall and temperature, the Demand Estimation Tool output consists of monthly demands for a specific sequence of hydrologic years as input by the user. The base water demand is calculated, aggregating the premise level demand across customer groups, for a predicted number of premises. The total demand includes the base demand, the supply obligations for the large commercial users (LCUs) and the estimated general distribution losses. The water demand can be estimated for different user specified grouping areas, including the FCU service area, the City, or its Growth Management Area (GMA).

The Demand Estimation Tool operates as a module of the DMS. The underlying data for the tool is parcel-based derived through spatial processing of GIS layers for grouping the variables by areas and sectors, attaching water use data and other demand drivers for the regression models. The final GIS layer attribute table, or Master Table, plays an important role in the demand estimation method, providing information to group parcels by service areas and apply densities in planning zones, for current and future predictions of water use in developed and undeveloped areas. One of the main assumptions in estimating the demand with the Master Table is that future planning zone characteristics (e.g., distribution of commercial and residential premises) are similar to current developed areas in the same zone.

4.2 FUTURE WATER DEMANDS

Because key factors affecting future water demand such as population growth, land development density and economic conditions are all uncertain, the WSVS used a scenario approach to assess the effects of water demand on water resources system performance. Three demand scenarios were developed by FCU for use in the WSVS. The demand scenarios are based on the most likely proposed future development trajectories developed as part of the Fort Collins City Plan update. The updated City Plan was adopted by City Council on April 16, 2019. The WSVS demand scenarios were developed with significant input from the City Planning Department and are based on assumed buildout conditions and 2070 population. These estimates should be reviewed and updated as new population and land use trends emerge for the City. The expected residential development densities by zone, as well as the expected split between single-family development and multi-family development for the City Plan 2 and 3 development scenarios are included in Appendix C. The demand scenarios are:

- City Plan 2 – This scenario was developed to estimate future (2070) water demands for the City Plan Development Scenario 2 – Targeted Changes. This development scenario forecasts more

dense residential development in some targeted areas of the City compared to current average residential density, mainly along existing commercial corridors.

- City Plan 3 – This scenario was developed to estimate future (2070) water demands for the City Plan Development Scenario 3 – Broad Changes. This development scenario expects even more dense residential development than in City Plan 2 across a broader set of planning zones, including a more significant shift towards multi-family units in lieu of single-family units. This scenario represents a reasonable upper bound to current expected development densities.

- City Plan 3 Plus 20% -- This scenario consists of a 20% increase of the City Plan 3 residential and general commercial demands and a portion of the LCU demands to represent unanticipated increased demands in the Fort Collins system due to factors not considered in the Demand Estimation Tool assumptions. For reference only, adding the demands associated with approximately 80% of currently undeveloped land outside the utility service area but inside the GMA plus the 20% increase in LCU demand results in nearly the same overall demands as represented by the City Plan 3 plus 20% scenario. This increase in demand could come from increased population, large commercial users, expansion of the service territory, or other factors that would stress supplies in all years and would be especially challenging in future hotter and drier climate conditions.

The demand scenarios used in the modeling system were created in the Demand Estimation Tool. For each demand scenario, the demand tool generated a time series of 86 years of monthly demands for all potential hydrologic scenarios. These time series were cataloged in the database and accessed when running the FCSys model. Note that none of the WSVS simulations include the effects of water use restrictions; thus, the demands developed by the Demand Estimate Tool were not reduced in accordance with the FCU Water Shortage Response Policy.

The number of future residential and commercial premises are estimated based on the dwelling unit densities in each zone district, the current density of commercial premises per zone district, the percent split of single-family versus multi-family development and a percent-built factor for each zone. The regression equations are used to estimate the monthly water consumption per premise for each of the five identified water use categories. The premise level monthly demand estimates are multiplied by the expected number of premises. The demand estimates include conveyance and distribution system losses. Details on the form of the regression equations and their coefficients are provided in Appendix C.

The components making up an estimate of the total FCU demand include:

- Residential and commercial indoor and outdoor demand, which includes a single estimate of commercial users with tap sizes between 6 and 8” not included in the LCU demands (Citydem node in the FCSys model);

- Large commercial users (LCU) with specified supply contract obligations, including Colorado State University, several breweries and several large manufacturers (LCU nodes in the FCSys model); and

- Contractual obligations to deliver C-BT water. These include obligations to City facilities and several homeowners' associations in the City, as well as agreements with surrounding water districts, municipalities and other entities. These are raw water demands as opposed to treated water demands. (CBTOblig node in the FCSys model).

The Demand Estimation Tool computes monthly demands for the Citydem node for each month in the 86-year simulation period based on the climate conditions in that month (tied to the hydrologic trace and climate condition being simulated) and the development scenario assumptions. LCUs and C-BT obligations are then added to the Demand Estimation Tool results to compute the total demand for a given scenario.

The Demand Estimation Tool as applied in the WSVS was used to generate monthly water demand values for the 86-year model period that represent one specific future condition. For example, for a water system simulation performed for 2070 conditions, the demand for every year in the 86-year simulation period will represent 2070 population and development conditions. Monthly and annual variability in demand are driven by climate factors. The purpose of the analysis is to investigate water resources system performance at a fixed point in the future (i.e., fixed population and development conditions) over a range of 86 years of variable hydrology. The WSVS analysis does not attempt to capture the incremental increase in demand from current conditions to some future condition over the 86-year simulation period.

The median average annual water demand in 2070 under City Plan 2 assumptions, including the effects of climate change is 37,700 AFY. The more aggressive growth assumptions in the City Plan 3 scenario result in a median average annual water demand of 39,200 AFY, for an increase of 4% compared to City Plan 2. The City Plan 3 Plus 20% scenario increased both the general residential and commercial portion of the total demand (i.e., Citydem node) and a portion of the LCU demand by 20%. However, the CBTOblig demands and the remaining portion of the LCU demands were kept constant. This resulted in a median total water demand of about 45,200 AFY. The average annual demand for 2065 based on previous FCU planning studies is 40,629 AFY. This was based on a future population of 178,000, 150 gallons per capita per day water use, and current C-BT obligations and LCU demands. This is referred to as the "Baseline demand" in this study.

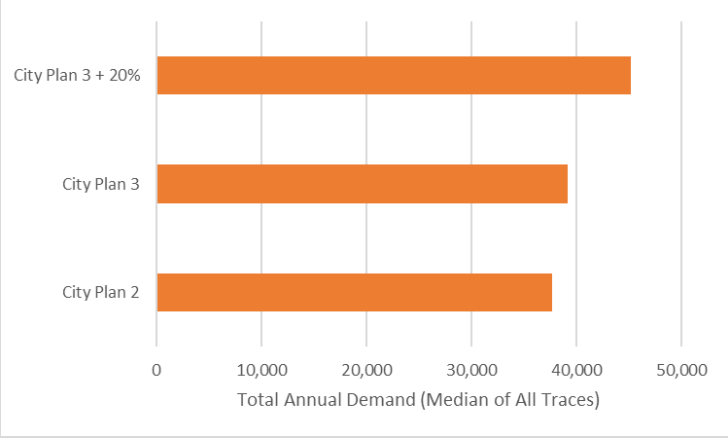

Figure 4-1 Total Annual Demand in 2070 Including Climate Change (Median of All 2,000 Possible Futures for Each Development Scenario)

Note: Average Annual Baseline Demand = 40,629 AFY

Figure 4-1 compares the total annual demands for these three scenarios. The impact of this range of demands on the FCU water resources system was

explored in the WSVS scenarios described in Section 6.

Because water demand is partially a function of weather, the monthly demand simulated by the Demand Estimation Tool is unique to each hydrologic time series it is paired with. **Figure 4-2** shows the simulated CityDem node annual demand for a single representative trace under the City Plan 3 Demand Scenario with a subset of climate adjustments. As shown, the demand time series have the same general pattern but are shifted according to the climate combinations. Impacts of long-term climate change can vary annual demands by about 14%. Impacts from inter-annual climate variability can vary annual demands by up to 10% within a given trace and temperature and precipitation. This shows that both long-term climate change and inter-annual climate variability can impact annual demands more than growth assumptions in City Plan 2 or City Plan 3.

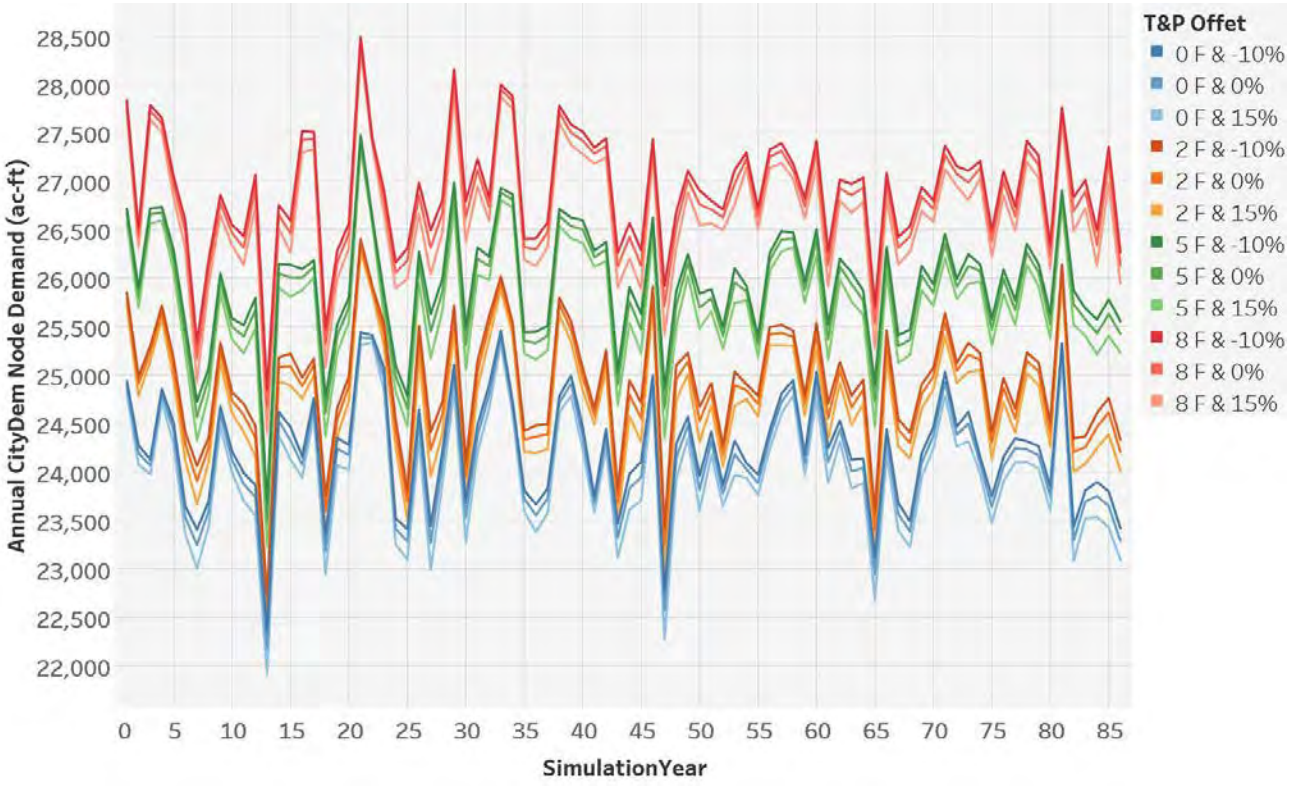

Figure 4-2 Annual Demand Variability in the CityDem Node for a Representative Trace with Select Climate Adjustments and City Plan 3 Development

Because 2,000 possible hydrologic futures were simulated for each of the demand scenarios (100 re-sequenced traces multiplied by 20 climate combinations for each), each scenario has an associated range of possible annual demands. **Figure 4-3** shows the median, minimum and maximum average annual demand for the 2,000 future possibilities generated for each of the two future development scenarios, as well as the City Plan 3 + 20% scenario. As shown in **Figure 4-3**, the average annual demands for City Plan 2 and City Plan 3 are typically lower than the “baseline demand”. The baseline demand for the WSVS was developed from existing FCU demand planning estimates, modified to reflect

similar demand estimate methods as developed for the Demand Estimation Tool. The WSVS City Plan 2 and City Plan 3 general residential and commercial demands are lower than baseline in all cases, but the LCU portions are larger. The LCUs and CBTOblig demands are based on contracts that are not dependent on climate, hydrology or other factors, so they are the same for all scenarios. The highest average demand scenario for City Plan 3, associated with a hydrologic trace with long periods of drought and a warmer climate, has a higher average annual demand than the baseline. This plot shows how the overall averages of the scenarios compare to each other, including variability of the minimum and maximum values; however, the interannual variability of the demand timeseries is seen in **Figure 4-2** above.

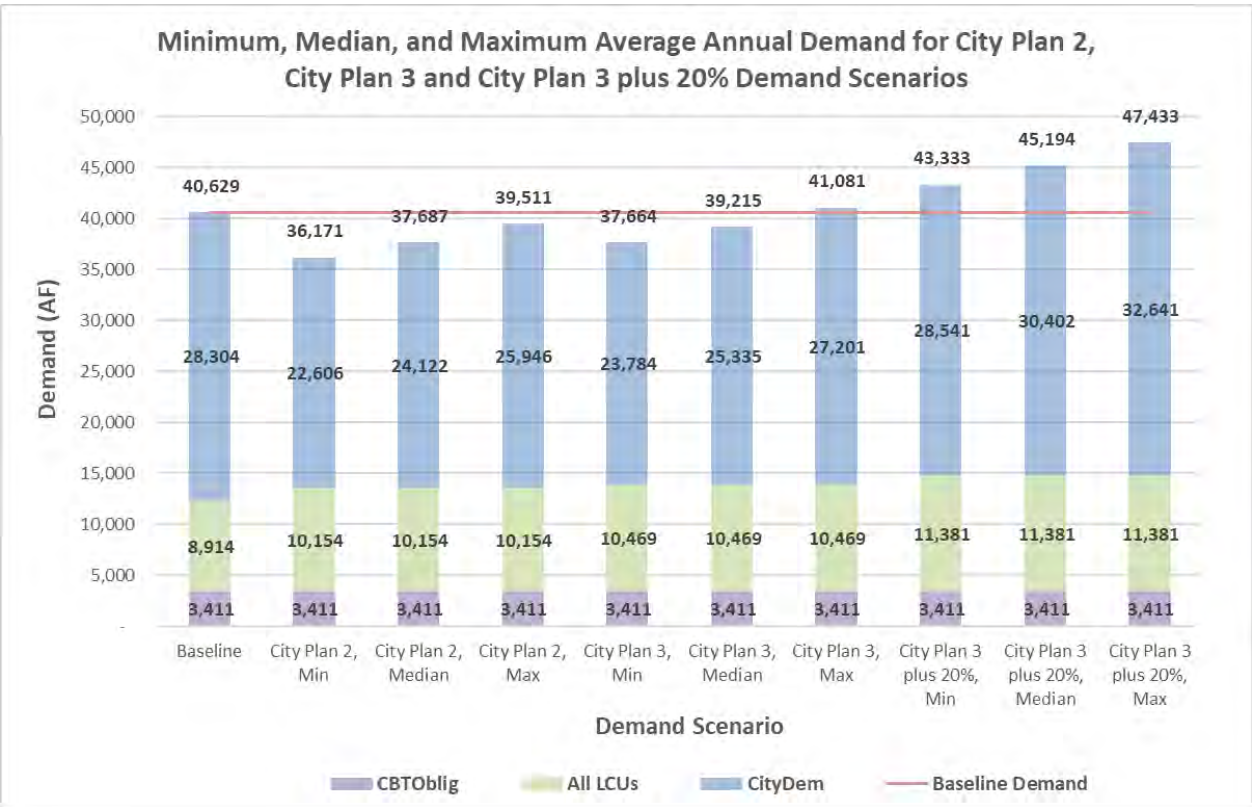

Figure 4-3 Comparison of 86-year Average Annual Demands for Demand Scenarios

Notes:

a) There are 2,000 timeseries of 86-years behind each demand scenario. The average annual demand was determined for each timeseries, and the minimum, median, and maximum values are included in the chart. The CityDem value represents the population and general commercial based demands, which vary based on weather inputs.
b) Baseline has an estimated population of 178,000. City Plan 2 has an estimated population of 179,000. City Plan 3 has an estimated population of 195,000.
c) City Plan 3 Plus 20% represents a demand scenario independent of an estimated population. This situation could present itself in a variety of ways. One example is presented earlier in Section 4.2.

The assumptions used to develop the WSVS demands are different than those used to develop the baseline demand. The baseline demand used a single population forecast and an assumed per capita

use rate based on historical water use patterns and an allowance for uncertainty. The previous demand estimation methodology accounted for some variability in year to year demand based on hydrologic conditions, but in a less robust way than in the Demand Estimation Tool. The functionality of the Demand Estimation Tool provided the variability needed to investigate the sensitivity of the Fort Collins water resource system performance to a range of possible future demands in the WSVS.

Figure 4-4 and **Figure 4-5** show the effect of climate conditions on general residential and commercial demand for the City Plan 2 and City Plan 3 demand scenarios. Each cell in the tables shows the average annual demand over the 100 hydrologic traces for the given T and P combination, as well as the percent increase or decrease compared to the T=0/P=0 average annual demand for the specified demand scenario. It is seen that changes in precipitation would have minimal effect on average annual demand but increases in average temperature of 8 degrees F would increase municipal water demand by up to 12 percent. Because higher temperatures would also be associated with lower water supply, this condition could represent a significant threat to the FCU water resources system.

	Delta P				
Delta T	-10%	-5%	0%	7%	15%

Figure 4-5 Effect of Climate on Annual Water Demand (Citydem only) for City Plan 3

Note: The bottom value in each cell is the average of the 86-year average annual demand for CityDem in acre-feet across the 100 traces for the specified future climate condition. The top value in each cell is the percent difference from the T=0/P=0 cell.

Figure 4-6 shows more detail on the effect that climate has on demand. This figure depicts the minimum, maximum and average annual demands across all years and traces for each of the climate scenarios and reiterates that demand is more impacted by temperature increases than by changes in precipitation. The difference between minimum and maximum annual demand for any climate variation is about 6,000 AFY. While the maximum and minimum in the figure did not necessarily come from the same trace, it is possible for FCU to see differences in annual demand this large between years.

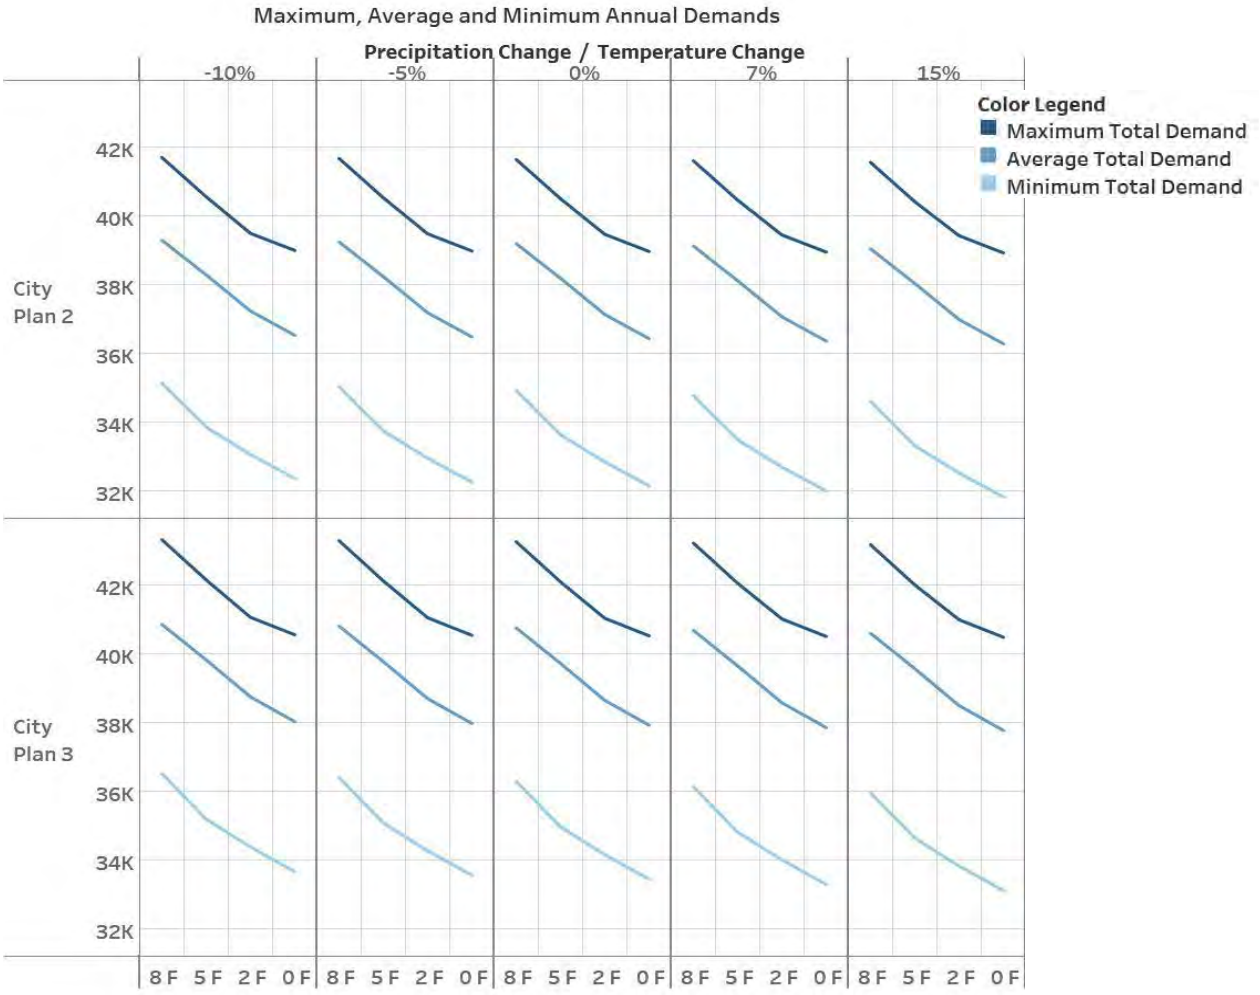

Figure 4-6 Maximum, Average and Minimum Annual Trace Demands

Notes:

a) Y-axis units are acre-feet
b) The shading of each line represents the maximum (darkest shade), average (medium shade) or minimum (lightest shade).
c) The maximum and minimum values are taken from the list of all 100 traces for each climate condition. Each point plotted represents the annual demand for a single year of a single trace.
d) The average values are taken from all years and all 100 traces. This data is most similar to what is plotted in Figure 4-4 and Figure 4-5, except this plot is the total demand and not only CityDem.

5.0 RISKS AND UNCERTAINTIES

This section summarizes the methodology and results of the process to identify and prioritize risks and uncertainties to the FCU water supply system. The purpose of the risk and uncertainty assessment was to look out 50 years and forecast events that could adversely affect FCU water supplies or infrastructure. The 50-year timeframe is the period adopted for the WSVS. It is recognized that anticipating conditions that may exist 50 years in the future is highly speculative. However, for purposes of the WSVS it is appropriate to investigate a broad range of possible future conditions to determine which conditions could stress the performance of the current water supply system.

The spatial scope of the WSVS includes source water areas and infrastructure upstream of the FCU water treatment plant. In addition to local Poudre River Basin supplies, the scope includes supply derived from the C-BT Project. Therefore, risks and uncertainties were identified by both FCU staff and Northern Water staff. Separate but consistent methods were used to identify and prioritize risks and uncertainties associated with FCU local supplies and with supplies provided by Northern Water from the C-BT Project.

A more detailed discussion of the risk and uncertainty analysis is in the Water Supply System Risk Identification Technical Memorandum (Stantec, 2018c), contained in Appendix B.

5.1 METHODOLOGY

Risks and uncertainties that could affect the future performance of the FCU water supply system were brainstormed in workshops held at Fort Collins Utilities and Northern Water. Identified risks and uncertainties were organized in the following categories that span the various aspects of the FCU water supply system.

- ***Climate and Hydrology*** risks relate to weather variability and other hydrologic factors, both short- and long-term, that can impact the potential yields from a watershed.
- ***Watershed*** risks relate to physical watershed conditions that can impact the yields available to FCU.
- ***Operational and Infrastructure*** risks relate to how FCU delivers physically and legally available water to its treatment facilities.
- ***Administrative and Legal*** risks relate to conditions, regulations, or policies that could impact the legal allocation or availability of water supplies.
- ***Demand*** risks relate to changes in required volume, timing and quality of water that will need to be delivered to water treatment facilities to meet customer needs.

Some risks are long-term, or chronic and would persist indefinitely and affect all future years. Other risks are short-term, or acute and would only occur for a short period of time (e.g., several months or a few years). Although long-term and short-term risks could have very different impacts on the FCU raw water system performance, both types of risks were assessed together in the WSVS.

The identified risks were rated as part of the prioritization process. Individual risks were rated by assigning a 1 to 5 score for both likelihood (possibility of the risk or uncertainty occurring) and impact (consequences to the FCU/C-BT water supply system if the risk or uncertainty were to occur) according to the definitions in **Table 5-1**. The composite score was calculated by multiplying the likelihood score by the impact score and was then used to prioritize risks.

Table 5-1 Definitions of Likelihood and Impact Used in Risk Rating Process

Score	Likelihood Definition	Impact Definition
1	***Rare*** – the risk will only occur in exceptional circumstances.	***Insignificant*** – If the risk occurs the impact to the water supply system would be negligible.
2	***Unlikely*** – the risk will occur in occasional circumstances.	***Minor*** – If the risk occurs the impact to the water supply system would be minimal.
3	***Possible*** – the risk will occur in some circumstances.	***Moderate*** – If the risk occurs there would be a noticeable impact to the water supply system.
4	***Likely*** – the risk will occur in a majority of circumstances.	***Major*** – If the risk occurs there would be substantial impact to the water supply system.
5	***Almost Certain*** – the risk will occur in almost all circumstances or is imminent.	***Extreme*** – If the risk occurs there would be extensive or catastrophic impact to the water supply system or customers.

5.2 FORT COLLINS WATER SUPPLY SYSTEM RISKS AND UNCERTAINTIES

Risks and uncertainties to the FCU water supply system were identified and prioritized by FCU staff members representing a variety of groups within the organization during a half-day workshop. Workshop attendees included representatives from water supply, water treatment, demand and conservation, watershed management, legal and water operations groups. FCU identified a total of 46 risks and uncertainties. Each of the identified risks and uncertainties were prioritized, selecting those that would be simulated. All risks with a composite score of 12 or above (out of a possible 25) were deemed impactful enough to warrant further examination and potential simulation. In addition, all risks that received an impact score of 4 or 5 were examined further, as these risks could be significantly impactful, even if their likelihood of occurring was low. Of these highly impactful risks, an outage of Joe Wright Reservoir (O8) and an outage of the Pleasant Valley Pipeline (O11) were prioritized for further analysis. An expanded description of each of the risks and the priority score they were given can be found in the *Water Supply System Risk Identification Technical Memorandum* contained in Appendix B. The prioritized risks and uncertainties were organized into five major threat groups that span the various risk categories. These threat groups are climate change, demands, critical outages, enhanced environmental stressors and shared infrastructure (i.e. risks or uncertainties due to lack of infrastructure ownership by FCU). **Table 5-2** lists all the key risks and uncertainties prioritized for simulation and indicates their threat group.

Table 5-2 List of Key Risks and Uncertainties Prioritized for Simulation

ID	Risk or Uncertainty Name	Threat Group	Description
O1	Outage - 24 Pipeline	CO	Short term outage due to flooding, landslides, wildfire, etc.

FORT COLLINS WATER SUPPLY VULNERABILITY STUDY

RISKS AND UNCERTAINTIES

ID	Risk or Uncertainty Name	Threat Group	Description
O2	Outage - 27 Pipeline	CO	Short term outage due to flooding, landslides, wildfire, etc.
O3	Algal Blooms	EES	Algal blooms in storage reservoirs and rivers increases water quality issues and potential treatment problems.
C1	Longer duration droughts	CC	Multi-year and/or more severe droughts occur in the future that are not captured in the observed record.
A1	New Regulations	EES	New regulations (either federal or state) impact availability of yields from existing water rights.
W1	Wildfires	EES	Wildfires occur, causing a variety of impacts on water quality, runoff and threats to infrastructure.
C3	Change in precipitation type - Hydrology	CC	More precipitation falls as rain instead of snow during the Fall and Spring.
C4	Changes in frequency/ magnitude of precipitation events - Hydrology	CC	Precipitation events, particularly summer rainstorms, become less frequent and more intense.
C2	Changes in runoff timing	CC	Early higher runoff and lower late-season baseflow reduces yield from volumetric decrees that list specific diversion dates.
W2	Forest Health Degradation	EES	Forested area health decreases due to beetle kill, pollution, warming climate, etc.
A4	Changing state administration	CC	Policies around state water administration change, impacting yields from water rights
D3	Development Uncertainty	D	The composition of development in service area (e.g. density, type, outdoor area) is different that past.
A2	Increased Basin Demands	D	Higher demands across the entire Poudre River basin (due to climate change/population growth) impact use of water rights.
O5	Outage - Horsetooth Reservoir Intake	CO	Short term outage of reservoir outlet and intake to WTP; higher risk due to lack of redundancy.
O4	Outage - Michigan Ditch	CO	Short term outage due to flooding, landslides, wildfire, etc.
D2	Water Use Changes	D	Decrease in per capita use continues and how water is used (e.g. indoor vs. outdoor) changes.
D1	Service area growth and Regionalization	D	Ft. Collins expands its service area or enters into agreements to provide water to regional entities.
A9	Elimination or Interruption of Reuse Plan	SI	Platte River Power Authority decommissions Rawhide Energy Station, effectively eliminating the need for the Reuse Plan. In multi-year droughts, water from the Reuse Plan is reduced or unavailable.
D8	Change in precipitation type - Demands	CC	More precipitation falls as rain instead of snow during the Fall and Spring.
D9	Changes in frequency/ magnitude of precipitation events - Demands	CC	Precipitation events become less frequent and more intense.
A3	Changes to Northern Water C-BT Operations	SI	Allocation of C-BT water through setting of the quota and ways in which C-BT water can be managed, changes in the future.

ID	Risk or Uncertainty Name	Threat Group	Description
W3	Development in Watersheds	EES	Land development in watersheds (recreation, residential, O&G, mining) increases risk of water quality contamination.
D6	Hotter summer changes irrigation	D	A warmer climate increases the length of the irrigation season and hotter days increase demand during the summer.
O6	Outage - Chambers Reservoir	CO	Short term outage due to flooding, landslides, wildfire, etc.
O8	Outage - Joe Wright Reservoir	CO	Short term outage due to flooding, landslides, wildfire, etc.
O11	Outage - Pleasant Valley Pipeline	CO	Short term outage due to flooding, landslides, wildfire, etc.

Note: CC = Climate Change, D = Demands, CO = Critical Outages, EES = Enhanced Environmental Stressors, SI = Shared Infrastructure

5.3 COLORADO-BIG THOMPSON SYSTEM RISKS AND UNCERTAINTIES

Risks and uncertainties to the C-BT Project were identified by staff members from Northern Water during a half-day workshop. Staff from Northern Water represented at the workshop included experts in water supply, watershed management, water quality and operations. While the primary goal was to generate risks around the C-BT system that would impact FCU, Northern Water generated risks across their entire C-BT collection and storage system. These same staff members then scored the identified risks using the rubric described in Section 3.1 based on their perceptions and professional judgment. Therefore, scoring is presented as a *perceived* threat to the water supply system; the actual impact to the water supply system was quantified later for selected key risks using the FCU water resources simulation models.

The scope of the Northern Water risk and uncertainty evaluation included the C-BT source watersheds, collection system and storage reservoirs. Risks to the delivery and distribution system were only considered insofar as they could affect deliveries to FCU. As with the FCU risk assessment process, the planning horizon was 50 years and risks and uncertainties were organized in the five categories of Climate and Hydrology, Watershed, Operations and Infrastructure, Legal and Administrative and Demand. Fifty-three risks and uncertainties were identified. The identified risks and uncertainties were prioritized, identifying those that would be simulated in the Fort Collins modeling system for quantitative analysis. An expanded description of each of the risks and the priority score they were given can be found in the *Water Supply System Risk Identification Technical Memorandum* contained in Appendix B. Similar to the process used by FCU, the first step to prioritize risks was to include all risks with a composite score of 12 or above (out of a possible 25). Northern and FCU felt these risks were impactful enough to warrant further examination and potential simulation. Additionally, all risks that received an impact score of 4 or 5 were further examined (regardless of their composite score) as these risks could be significantly impactful even if their likelihood of occurring was low. Of these highly impactful risks, those prioritized were:

- Conveyance system to Horsetooth Reservoir Outage (ON12)
- Adams Tunnel Outage (ON18)
- Farr Pump Plant Outage (ON17)
- Lake Granby Dam/Dike System Outage (ON19)

- Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project (AN2)
- Windy Gap Plant Outage (ON20)

The prioritized risks and uncertainties were then summarized around the same five major threat groups used by FCU: climate change, demands, critical outages, enhanced environmental stressors and shared infrastructure. **Table 5-3** lists the key risks and uncertainties prioritized for simulation and their threat group.

Table 5-3 List of Northern Water Prioritized Risks and Uncertainties

ID	Name	Threat Group	Description
CN1	Longer Duration Droughts	CC	Long-term droughts that have longer durations than occurred in past.
WN1	Changes in wildfire characteristics	EES	Increase in extent and severity of wildfires in high elevation forests degrades water quality, increases sediment loads and changes runoff characteristics.
CN2	Increased frequency of extreme dry years	CC	Years like 2002 and 2012 become more frequent.
ON1	Green Mountain Replacement Pool Inadequacy	D	If a change in hydrology reduces water supply in the Blue River drainage, the 52,000 acre-ft replacement pool may be inadequate to mitigate against a variety of future risks This could reduce Northern's ability to divert out-of-priority water.
WN2	Wildfires - Upstream of Grand Lake/Shadow Mountain	EES	Increased occurrence of wildfire leads to short term reduced capacity and ability to use Grand Lake/Shadow Mountain Reservoir. Long term channel and sediment changes.
WN3	Watershed forest health degradation	EES	Poorer forest health leads to increase in wildfire risk, water quality impacts, hydrology impacts and increased sediment load.
AN1	Environmental Regulations (changes, new, compliance)	EES	New regulations or changes in federal permitting compliance may lead to more water used for environmental mitigation/flows.
CN3	Changes in runoff volume	CC	Long-term reductions in runoff volume due to hotter, drier climate reduce overall yield.
ON3	Power Arm Outage	CO	Failure of Power Arm prevents moving water into Carter Lake
ON4	Southern Water Supply Project Outage	CO	Failure of Southern Water Supply Project prevents delivering water to southern allottees.
ON2	Unit No3 of Flatiron Facility Outage	CO	Failure of Unit 3 in the Flatiron Pump Station prevents pumping water into Carter Lake.
WN5	Increased sediment loading	EES	Increased sediment loading from several causes reduces reservoir or conveyance capacity and affects water quality.
WN4	Wildfires - East Slope	EES	Increased occurrence of wildfires in Big Thompson River basin degrades water quality and may prevent ability to use Big Thompson

ID	Name	Threat Group	Description
			River to move C-BT water. Watershed above Lake Estes has lower wildfire impact risk but higher likelihood.
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project	CC/CO	Possible changes in C-BT operations based on hydrologic uncertainties and a large C-BT Project outage.
ON12	Conveyance Systems to Horsetooth Outage	CO	Variety of events could cause outages or reduced in deliveries in conveyance system components to Horsetooth Reservoir.
ON18	Adams Tunnel Outage	CO	Tunnel failure prevents moving all C-BT/Windy Gap water to East Slope.
ON17	Farr Pump Plant Outage	CO	Pump station failure prevents moving water from Lake Granby to Grand Lake and Adams Tunnel.
ON19	Lake Granby Dam/Dike System Outage	CO	Reduced capacity due to safety reduction or other outage issue limits ability to move water to Grand Lake and Adams Tunnel.
ON20	Windy Gap Plant Outage	CO	Pump station failure prevents transfer of Windy Gap water into the C-BT delivery system.

Note: CC = Climate Change, D = Demands, CO = Critical Outages, EES = Enhanced Environmental Stressors

5.4 SIMULATION APPROACH FOR SELECTED RISKS AND UNCERTAINTIES

The impacts of the selected high priority risks and uncertainties on the water supply system were quantified using the FCU modeling system to provide objective information about which risks and uncertainties represent the most significant threats.

The risk and uncertainty simulation process required identification of the water supply feature being impacted by each key risk/uncertainty, the duration of the impact and determination of the models that should be used to simulate its effects. Some risks or uncertainties, although prioritized, were not explicitly simulated in the models though their specific impacts could be qualitatively described. Appendix B provides additional detail on how each of the risks and uncertainties was simulated in the FCU modeling system.

As described in Section 2, the following three models are linked in the FCU modeling system to represent FCU's water supply resources.

- The CBTQ simulates the anticipated quota for C-BT allottees based on hydrology, operations of the major reservoirs in the C-BT system and other factors.
- The PBN model simulates the water allocation and storage for water users in the Poudre River basin.
- The FCSys simulates the operation of infrastructure used to deliver yields from sources to FCU's water treatment plant.

Table 5-4 presents the adopted simulation approach for the prioritized risks and uncertainties related to the FCU water supply system. For risks with a simulation approach that is applied for a fixed period of time (e.g., June-October, 5 years), the simulated year in which the risk occurs was fixed (e.g. year 10 of the simulation) across all three models. Because 100 different hydrologic traces were simulated, risks occurring in the same simulated year were tested across a variety of hydrologic conditions (e.g., they could occur during short droughts, multi-year droughts, wet periods, or drought recovery periods).

Table 5-5 presents the simulation approach for the prioritized risks and uncertainties related to the C-BT water supply system.

Table 5-4. Simulation approach for FCU water supply system risks and uncertainties

ID	Risk or Uncertainty Name	Model for Simulation	Simulation Approach
O1	Outage – 24” Pipeline	FCSys	100% outage between October and March, when impact would be most severe to operations. Will be combined with 27” Pipeline Outage in model.
O2	Outage – 27” Pipeline	FCSys	100% outage between October and March, when impact would be most severe to operations. Will be combined with 24” Pipeline Outage in model.
O3	Algal Blooms	FCSys	C-BT water use will be shut off between June-October.
C1	Longer duration droughts	All	Incorporated into new stochastic hydrology
A1	New Regulations- Water quality and environmental	Not Simulated	New regulations impact wastewater discharge, minimal impact to water supply
W1	Wildfires	FCSys	Outage of non-C-BT supply between June-September, followed by 10-year, 20% reduction in non-C-BT-supply.
C3	Change in precipitation type - Hydrology	All	Incorporated into new stochastic hydrology
C4	Changes in frequency/magnitude of precipitation events - Hydrology	All	Incorporated into new stochastic hydrology
C2	Changes in runoff timing	All	Incorporated into new stochastic hydrology
W2	Forest Health Degradation	Not Simulated	Gradual water supply impacts over a long period of time that cannot be effectively simulated
A4	Changing state water rights administration	Not Simulated	Water supply impact of existing water rights minimal, greater potential impact on new or transferred water rights
D3	Development Uncertainty	FCSys/PBN	Captured in demand scenario modeling
A2	Increased Basin Demands	Not Simulated	A separate sensitivity analysis around this was completed by FCU and found no significant impact on water availability.
O5	Outage - Horsetooth Reservoir Outlet	FCSys	Horsetooth Reservoir empties in October, then 100% storage capacity reduction for 9

ID	Risk or Uncertainty Name	Model for Simulation	Simulation Approach
			months, though water can still flow through the reservoir.
O4	Outage - Michigan Ditch	FCSys	100% reduction for 24 months
D2	Water Use Changes	FCSys	Captured in demand scenario modeling
D1	Service area growth and regionalization	FCSys	Apply a percent increase to demands in new demand model based on how much demands may increase.
D8	Change in precipitation type - Demands	FCSys	Captured in demand scenario modeling
D9	Changes in frequency/magnitude of precipitation events - Demands	FCSys	Captured in demand scenario modeling
A3	Changes to Northern Water C-BT Operations	FCSys/PBN	Various factors cause C-BT quota to be 25% for 10 years.
W3	Development in Watersheds	Not Simulated	Minimal land in watersheds available for development
D6	Hotter summer changes irrigation	FCSys	Captured in demand scenario modeling
O6	Outage - Chambers Reservoir	Not Simulated	Mainly used to pass through yields, assumed that operational use could be maintained during outage
O8	Outage - Joe Wright Reservoir	FCSys	100% reduction in capacity for 24 months starting in November. All inflows bypassed.
O11	Outage - Pleasant Valley Pipeline	FCSys	100% reduction from April-October
A9	Elimination or Interruption of Reuse Plan	FCSys	A 100%, 75%, 50% and 25% reduction in the water available from the reuse plan for the entire simulation

Table 5-5 Simulation approach for C-BT Project water system risks and uncertainties

ID	Name	Model for Simulation	Simulation Approach
CN1	Longer Duration Droughts	CBTQ	Incorporated into new hydrology.
WN1	Changes in wildfire characteristics	Not Simulated	
CN2	Increased frequency of extreme dry years	CBTQ	Incorporated into new stochastic hydrology.
ON1	Green Mountain Replacement Pool Inadequacy	CBTQ	Reduce inflows into model to account for loss of out-of-priority diversions.
WN2	Wildfires - Upstream of Grand Lake/Shadow Mountain	Not simulated	Potential quota changes captured in other risks.
WN3	Watershed forest health degradation	Not simulated	Gradual water supply impacts over a long period of time that cannot be effectively simulated

FORT COLLINS WATER SUPPLY VULNERABILITY STUDY

RISKS AND UNCERTAINTIES

ID	Name	Model for Simulation	Simulation Approach
AN1	Environmental Regulations (changes, new, compliance)	CBTQ	Reduce inflows into model to account for loss due to increased environmental flows.
CN3	Changes in runoff volume	CBTQ	Incorporated into new stochastic hydrology.
ON3	Power Arm Outage	Not simulated	Doesn't impact quota setting or deliveries of C-BT supply to FCU
ON4	Southern Water Supply Project Outage	Not simulated	Doesn't impact quota setting or deliveries of C-BT supply to FCU
ON2	Unit No3 of Flatiron Facility Outage	Not simulated	Doesn't impact quota setting or deliveries of C-BT supply to FCU
WN5	Increased sediment loading	Not Simulated	Shadow Mountain Reservoir is mostly a pass-through reservoir, so may not be greatly affected by reduced capacity.
WN4	Wildfires - East Slope	CBTQ	Reduction in Big Thompson-captured inflows. No delivery of C-BT water to certain water users (e.g. Greeley) through Big Thompson River.
ON12	Conveyance Systems to Horsetooth Outage	FCSys	Doesn't impact quota setting. 100% reduction in C-BT delivery to Horsetooth Reservoir from January – June. Existing water in Horsetooth Reservoir still useable.
ON18	Adams Tunnel Outage	FCSys/PBN	100% reduction in West Slope yields for a single year.
ON17	Farr Pump Plant Outage	FCSys/PBN	60% reduction in West Slope yields for a single year.
ON19	Lake Granby Dam/Dike System Outage	FCSys/PBN	100% reduction in West Slope yields for a single year.
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project	FCSys/PBN	A reactive response that is a reduction in West Slope inflows resulting in a 25% C-BT quota for 10 years.
ON20	Windy Gap Plant Outage	CBTQ	100% reduction in West Slope yields for a single year.

6.0 RISK SCENARIOS

Risk scenarios were developed by FCU to represent combinations of future conditions for which a vulnerability analysis was desired. Scenarios are comprised of single or multiple risks described in Section 3 and are designed to allow FCU to understand how its water resources system would behave under a range of future stressful conditions. This section summarizes the scenario development process and briefly describes the planning scenarios selected for analysis. More detail on this process is provided in the Scenarios for Vulnerability Analysis Technical Memorandum (Stantec, 2018b) in Appendix F.

6.1 BASELINE CONDITIONS

To quantify the impacts of risks and uncertainties that make up each scenario, baseline conditions were established in each of the three models that comprise the Fort Collins Modeling System: the C-BT Quota Model, the Poudre Basin Network Model and the Fort Collins System Model. The baseline conditions across all three models establish the basic model initial settings and do not include any identified risks, new demand model projections or climate altered hydrology. The baseline conditions are intended to represent the most reasonable future for planning purposes under the future demand historically used by FCU in its previous modeling.

Baseline conditions are described in Appendix F. Key aspects of the baseline conditions include:

- Constant annual demand of 40,629 AFY (the baseline demand described in Section 4)
- Current FCU and C-BT water supply infrastructure
- Halligan Reservoir Enlargement of 8,125 AF as currently proposed
- C-BT carryover storage “on”
- Current water rights portfolio with assumed future acquisitions
- Current operation of FCU’s water supply infrastructure

Results of water supply system performance under the baseline conditions were used to test the functionality of the updated model constructs and new modeling system.

6.2 SCENARIO DEVELOPMENT METHODS

In general, a WSVS scenario consists of three parts:

- A climate condition, defined as one of the 20 temperature and precipitation combinations, which determines 100 hydrologic traces representing climate variability around that climate condition as described in Section 5.

- A demand condition, defined as one of the two future City Plan demand scenarios described in Section 4. (The City Plan 3 + 20% demand scenario encompassing conditions beyond those currently anticipated by the City Planning Department was only included in the Increased Demands risk scenario described below because it represents a risk that demands would significantly exceed the range of demands associated with conditions currently being planned for by the City.)
- A system risk condition, defined as a combination of one or more of the risks and uncertainties described in Section 5.

The process for creating WSVS scenarios is shown in **Figure 6-1**

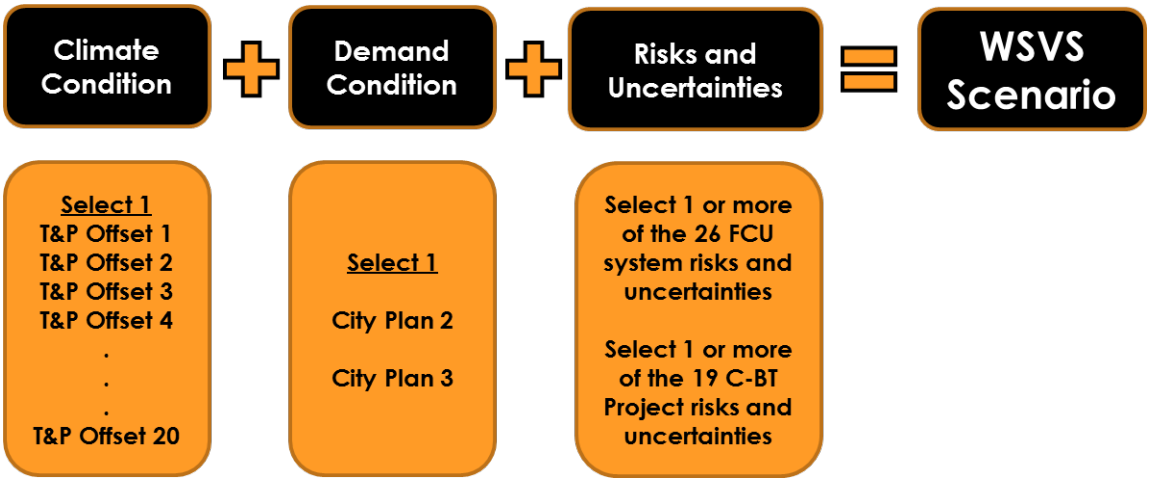

Figure 6-1 Process of Creating WSVS Scenarios

6.3 ADOPTED PLANNING SCENARIOS

FCU Staff, in coordination with Northern Water, identified 13 scenarios for simulation, including the baseline scenario. The 12 non-baseline scenarios were selected to represent a range of future conditions believed to be possible and potentially impactful to the FCU water resources system. They represent both long-term or chronic conditions (i.e., those that occur over the entire simulation period) and short-term or acute conditions (i.e., those that occur for only a short period of time). The WSVS scenarios are briefly described below.

- Climate Change Impacts –This scenario includes the full hydrologic ensemble of 100 traces and captures the full range of potential future climate change conditions resulting in 2,000 hydrologic scenarios. It uses a constant annual future demand of 40,629 acre-feet. It does not include

additional system risks. It is used for isolating the potential effects of climate change on FCU system performance.

- Loss of Storage –This scenario captures the impacts to the water supply system if the Halligan Reservoir expansion (8,125 AF) does not happen and if FCU loses its C-BT Carryover Storage account in Horsetooth Reservoir. Decisions regarding both actions are ultimately beyond FCU's control. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demand scenarios.

- Increased Demands –This scenario includes the three demand scenarios described in Section 4 – City Plan 2, City Plan 3 and City Plan 3 Plus 20%. It does not include additional system risks. It is useful in isolating the potential effects of increased demand on FCU system performance. Each of these demand scenarios was simulated with the full 2,000 hydrologic scenarios.

- No Halligan Enlargement – The baseline condition includes the 8,125 AF expansion of Halligan Reservoir as currently proposed. At the time of this study the Halligan Reservoir enlargement project has not been permitted and therefore there is no guarantee it can be implemented. Because of the uncertainty around that assumption, this scenario is included to represent a future condition without the expansion of Halligan Reservoir. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- Poudre River System, Acute Outage – Infrastructure to deliver yield from the Poudre River to the city is potentially vulnerable to failures due to either natural disasters (landslides or wildfires) or emergency maintenance outages. This scenario captures the impact of a short-term simultaneous outage of the 24-inch Pipeline, the 27-inch Pipeline and the Pleasant Valley Pipeline. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- C-BT System, Environmental Impacts – This scenario quantifies impacts on C-BT quota allocations due to environmental issues resulting from wildfires in the receiving East Slope watershed or restricted use of Horsetooth as a water source because of algal blooms. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- Poudre River System, Environmental Impacts –This scenario quantifies impacts on water supply performance due to algal blooms or environmental issues resulting from wildfires in source watersheds (e.g. increased sediment deposition) that would limit FCU's diversions from the Poudre River. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- C-BT System, Acute Outage –There are a variety of potential causes for a short-term outage of critical C-BT delivery infrastructure such as an outage of the Adams Tunnel or Farr Pumping Plant. This scenario captures the impact of this C-BT infrastructure risk to the performance of the FCU water supply system. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- C-BT System, Long-Term Reduction – For purposes of the WSVS, FCU assumed that in the event of a long-term C-BT Project outage, the C-BT quota will be set to 25% for a 10-year period. This assumption was made by FCU based on total storage capacity in the C-BT system and the potential length of this type of outage. It is intended to capture the possible effects of a wide range of conditions that could affect C-BT deliveries over an extended period of time. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- Horsetooth Reservoir Outage – Lack of redundancy with the Horsetooth Reservoir outlet works puts deliveries of FCU's C-BT yield from this reservoir at risk. Recent problems with the outlet works have shown that this type of risk can occur. This scenario was simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

- Reuse Plan Changes –This scenario is actually two scenarios which capture impacts to FCU water supply system performance due to changes to the Reuse Plan that would reduce the available supply to FCU. One scenario reduced the use of the Reuse Plan by 50% and another eliminated it altogether. These scenarios were simulated with the full 2,000 hydrologic scenarios for both the City Plan 2 and City Plan 3 demands.

7.0 VULNERABILITY ASSESSMENT

7.1 INTRODUCTION

This section summarizes the results of the Water Supply Vulnerability Study. It presents the result of key modeling analyses using visualization templates developed specifically for this project. Many thousands of model simulations were performed, and dozens of metrics were explored as means of understanding the response of the FCU water supply system to different stressors. This section includes selected displays; many other sets of results were separately provided to FCU, in the form of Tableau files.

As described in Section 5, many factors could negatively impact FCU's ability to reliably meet future water demands. These factors include hydrologic risks due to climate variability and climate change; increased demands due to population growth or changes in development density; and risks to the water supply system such as legal and regulatory changes, environmental factors, aging infrastructure, etc. The impacts of these various risks on the FCU water supply system were investigated in a systematic manner based on the steps outlined below and shown in **Figure 7-1**.

- Determine the system's baseline scenario performance before the addition of altered hydrology or demands.
- Investigate how potential climate change could affect the performance of the baseline system.
- Assess the impacts of increased demands generated by the new Demand Estimation Tool in combination with the climate-adjusted hydrologies.
- Evaluate the superposition of the risk scenarios described in Section 6 with the climate hydrologies and each City Plan demand scenario.
- Identify the individual risks and risk combinations with the greatest potential to adversely affect the FCU system performance.

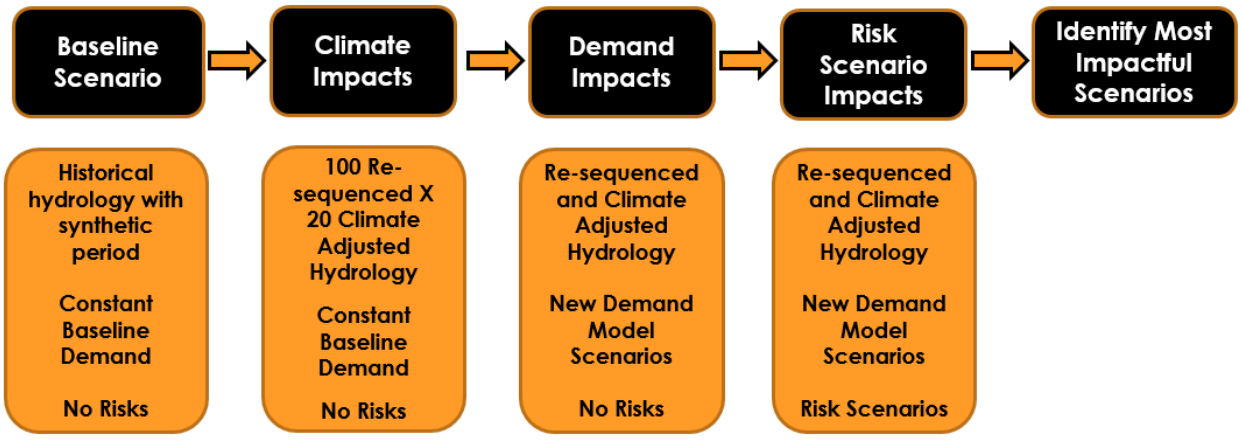

Figure 7-1 Method for Risk Evaluation

Many performance metrics were identified to help quantify the impacts of these risks. As the WSVS progressed, FCU staff found that the following four performance metrics were most useful for identifying the impactful risks.

- Average annual total demand shortage in years when shortages occur
- Reliability (i.e., frequency) of maintaining 20%of annual demand in storage (storage reserve factor)
- Percentage of years in which conditions would trigger any level of water use restrictions per the current water supply planning policy and Water Shortage Response Policy
- Indoor demand reliability

Section 2 describes the relationship between metrics (measures of system performance) and level of service goals (metric values that define acceptable vs unacceptable performance). For purposes of the WSVS, the current FCU water supply planning policy criteria described in Section 2.2 were used as level of service goals by which to assess the impacts of the various risks and uncertainties.

As described previously, WSVS simulations were performed without applying demand reductions due to implementation of water use restrictions, consistent with the Water Shortage Response Policy. As such, the metric for “percentage of years in restrictions” represents the percentage of years one or more of the water supply planning policy criteria would not be met and FCU would have to implement some type of management response (e.g., water use restrictions, emergency supplies, other demand management strategies). The restriction metric captures times when a violation of any of the water supply planning policy criteria (100% demand reliability, 100% SRF reliability) would occur. Because the WSVS modeling does not capture any possible carryover benefit of restrictions or management measures from one month or year to the next, results for this metric overstate the actual percentage of years these conditions would occur if management measures were implemented. However, the metric is still valuable for relative comparison of water supply system performance impacts between different future scenarios.

FCU decided that additional level of service goals would not be considered when evaluating system performance for the WSVS. Establishment of new level of service goals based on the results of the vulnerability assessment modeling was considered a policy decision, and thus it was postponed until the Water Supply and Demand Management Policy is updated based on the results of the WSVS.

The following sections describe the results of the WSVS modeling.

7.2 BASELINE PERFORMANCE

Assumptions for baseline conditions were established in the three models included in the WSVS: The C-BT Quota Model, the Poudre Basin Network Model and the Fort Collins System Model and were described in Section 6. The baseline simulation included a constant annual future demand of 40,629 AFY. It did not include any identified risks or climate altered hydrology. Instead, the historical hydrology with a synthetic period was used, to be consistent with previous modeling efforts by FCU. The conditions in which the baseline scenario was run were intended to represent the most reasonable future condition in which historical conditions persist and no additional improvements are made to the FCU water supply system beyond the proposed Halligan Reservoir enlargement and currently anticipated water acquisitions.

Figure 7-2 compares two sets of model runs: the baseline simulation, as defined above and the baseline settings, run under current climate conditions (T=0, P=0), across all 100 traces and averaged. Ideally, the metrics from both sets of runs would be identical, meaning the new modeling method that utilizes re-sequenced hydrologic traces does not perform significantly better or worse than the method previously used by FCU.

It can be seen in **Figure 7-2,** that both the baseline simulation and the current climate conditions simulations perform similarly for the existing system, including the proposed Halligan Reservoir enlargement. Both sets of simulations are able to meet all demands, including Reuse Plan demands, with 100% and 99.1% reliability (i.e., there is a shortage in only 9 of the 1,032 months of simulation). Indoor demands are met 100% and 99.8% of the time (2 months of shortage out of 1,032). The results also showed that the system maintained the required 20% storage reserve factor 98.8% and 97.1% of the total simulated months (i.e., the 20% storage reserve factors were not maintained in only 12 and 30 out of the 1,032 months of simulation). Note that none of the WSVS simulations include the effects of water use restrictions.

Figure 7-2 also shows the average lengths of shortages and the average volumes of those shortages when they occur. For example, when FCU cannot meet the 20% storage reserve factor, the average number of consecutive months of shortage is 1.2 months for the baseline simulation and an average of 2 months for the current conditions scenario. The average monthly shortage volume is 2,121 AF for the baseline simulation and 2,358 for the current conditions scenario. These values are manageable within current policies and available management strategies.

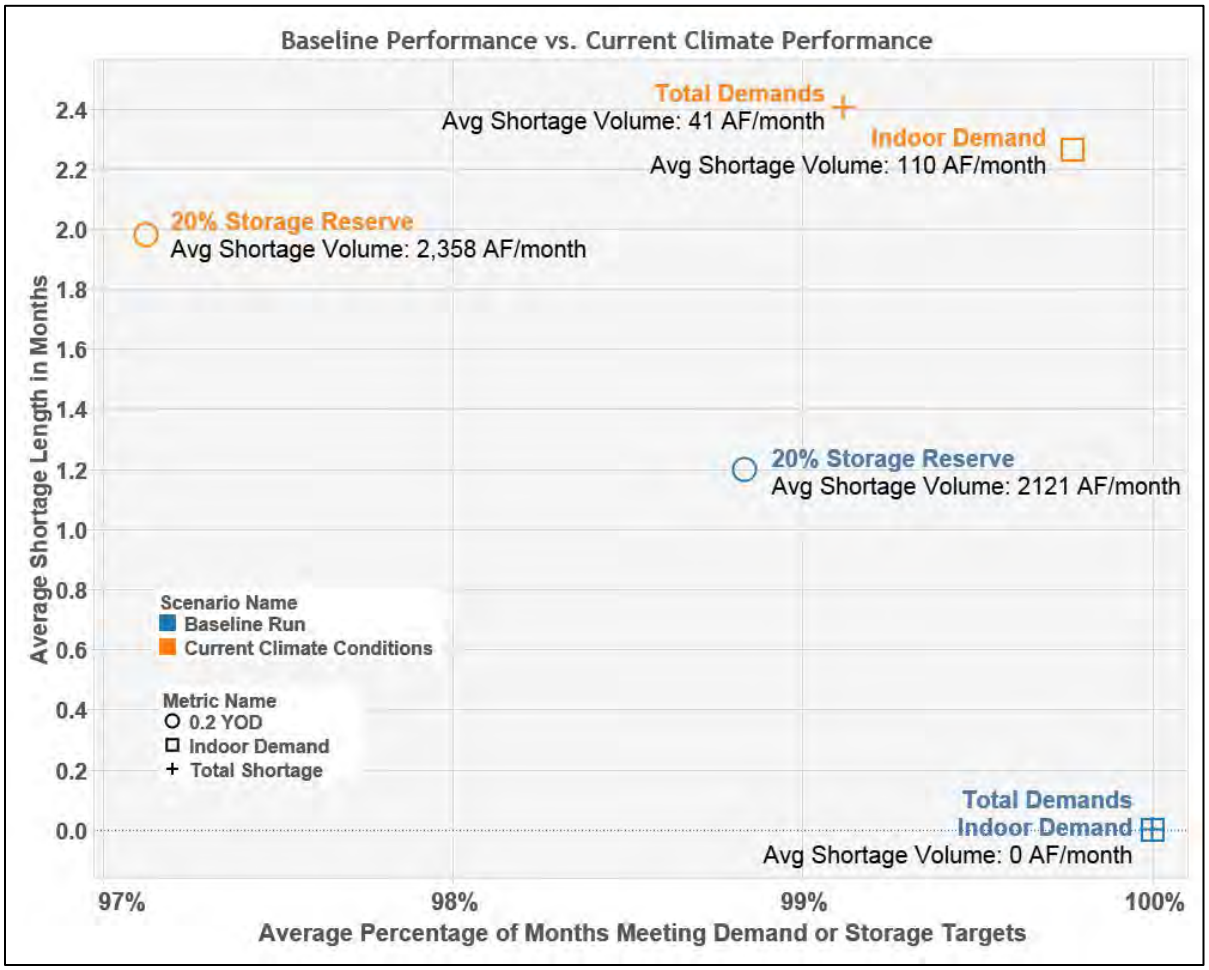

Figure 7-2 Baseline Performance Compared to Current Climate Performance for Three Key Metrics

These results demonstrate that the updated modeling method used for the WSVS is consistent with past FCU methods. The results also demonstrate that FCU has been successful in planning for and developing a water rights portfolio and water supply infrastructure to meet its customers' water needs under future baseline conditions and planned operation of its raw water systems. As shown in Section 4, the baseline demands used in this part of the analysis are similar to the future City Plan 2 and City Plan 3 demands developed for the WSVS; therefore future performance of the current water resources system under either of these other demand forecasts should be similar to the baseline results described above. It is noted again, that the baseline conditions for WSVS include the proposed Halligan Reservoir enlargement of 8,125 AF. As shown in subsequent sections, this additional storage is critical to maintaining desired system performance under more stressful future conditions.

7.3 CLIMATE VARIABILITY AND CLIMATE CHANGE VULNERABILITY RESULTS

After the baseline analysis, the Climate Change Impact scenario was simulated to evaluate the vulnerability of the FCU raw water system to climate variability and climate change. This scenario applied the 20 combinations of temperature and precipitation changes to the baseline model with a constant annual demand of 40,629 AFY without simulating any system risks, thereby isolating the potential effects of climate on the FCU system performance.

The reliability metric can be calculated either on an annual basis or a monthly basis. In the annual calculation, a shortage in one month of the year counts the entire year as a failure, whereas the monthly calculation is more of a true reliability calculation.

Figure 7-3 shows both the annual and monthly reliability for three key metrics for the current climate scenario. The blue shapes are monthly reliability calculations and the orange shapes are annual reliability calculations. The different shapes represent the three different metrics; total demand, indoor demand and 20% storage reserve. Annual reliability is always less than or equal to the monthly reliability.

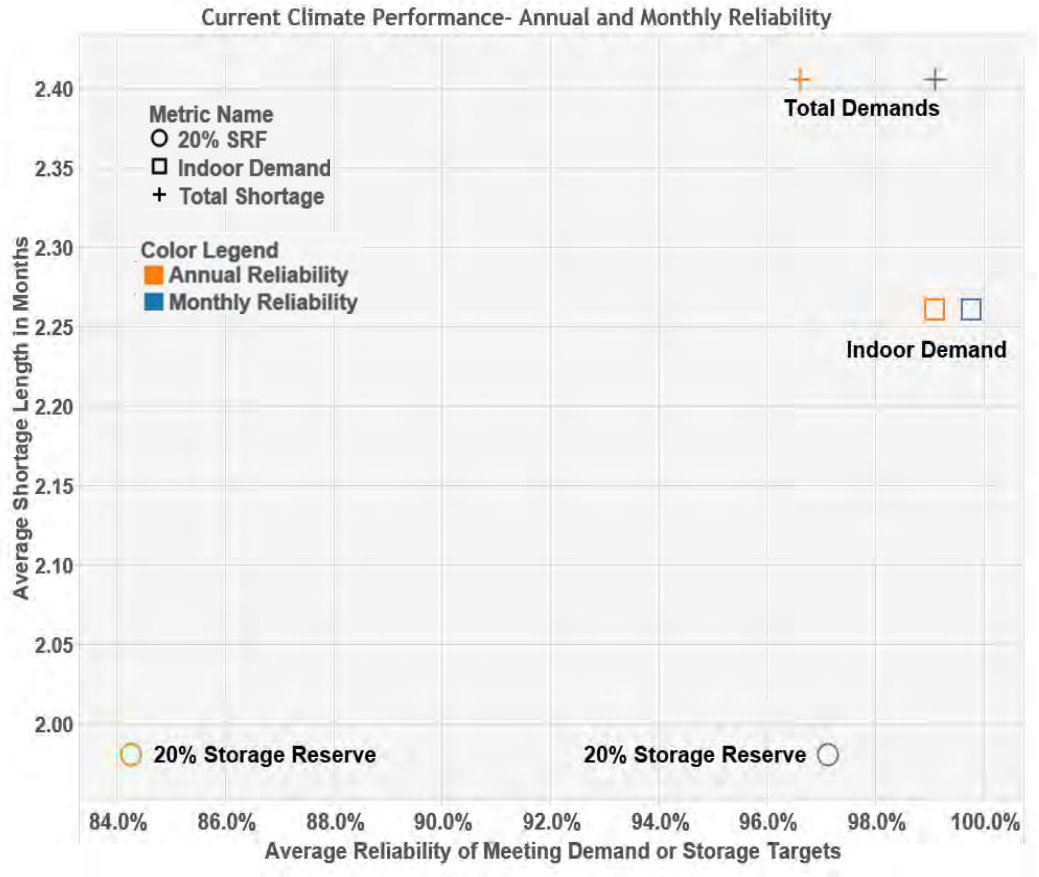

Figure 7-3 Comparison of Annual and Monthly Reliability

Reviewing annual reliability is perhaps more intuitive for many of the metrics, but the annual calculation can mask important information. If shortages occur only in one month every year, the annual reliability may be very low, even though the system may be performing without shortages for the majority of the year. Conversely, reviewing monthly reliability may be a bit more difficult to grasp, but is more of a true reliability calculation. If shortages occur only one month every year, the overall monthly reliability will be high, but there is no way to tell from the monthly reliability if the shortages occurred in each year or if the shortages occurred in a single year because of a drought. Only by looking at both annual and monthly reliability metrics is the full story available.

These results show that for the metrics related to the current water supply planning policy, the 20% storage reserve factor has the lowest reliability and thus, is the most difficult criterion to meet for baseline conditions. Normal operations would have to be modified (e.g., through implementation of water use restrictions, alternate operating rules, or acquisition of emergency supplies) in about 3% of the months and 16% of the years. This is typical of FCU's historical experience of requiring watering restrictions 1 in every 10 years.

7.3.1 Results for Selected Metrics

The results summarized in the following "heat maps" depict the average value of the specified metric over all 100 hydrologic traces in each of the 20 T/P climate combinations. As described in Section 3, hydrologic traces represent climate conditions with 0 to 8 degrees F warmer annual temperatures and – 10% to +15% change in annual precipitation.

Figure 7-4 shows the average percentage of months in which all system demands were met. At the 0-degree temperature increase and 0% precipitation change level (i.e., the 0/0 cell), total demands are met in 99.1% of the months of simulation. The heat map shows how system performance responds to climate conditions. As climate gets warmer and drier, the reliability of meeting total system demands decreases (i.e., shortages occur more frequently). In the extreme condition of 8 degrees warmer and 10% less precipitation, total system demands can only be met in 62.9% of months. Results suggest that the FCU water resources system can tolerate warmer temperatures when annual precipitation is at or above historical conditions. If annual precipitation decreases or remains constant, any temperature increase would have a significant adverse impact on FCU system performance.

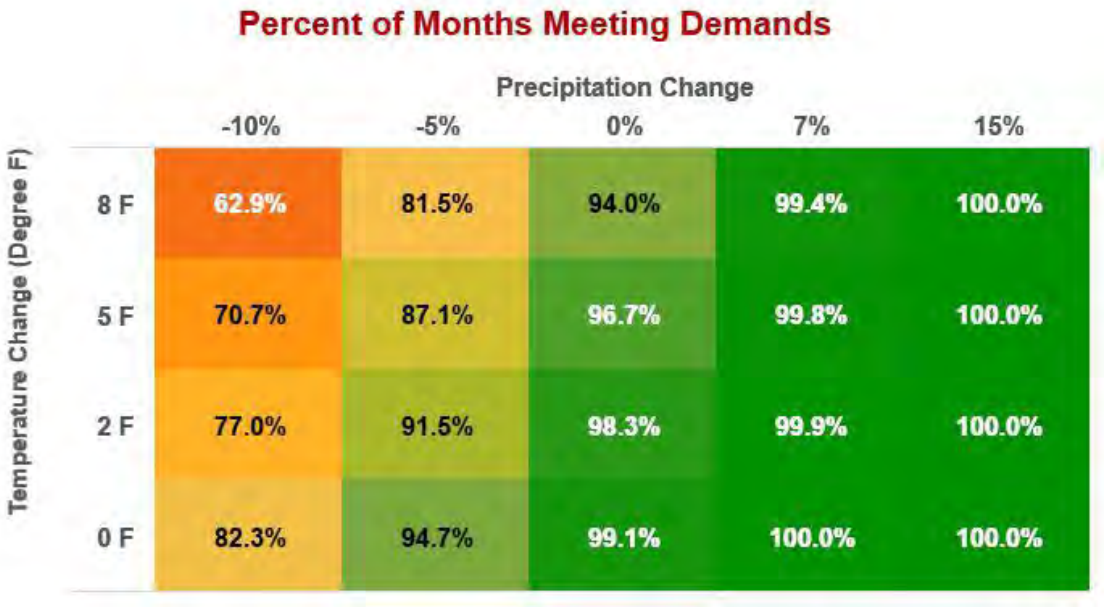

Figure 7-4 Average Monthly Reliability of Meeting Total Demands for All Climate Conditions

Note: The value in each cell is the average of the percentage of months in which total demands are met across the 100 traces for the specified future climate condition.

Figure 7-5 shows the average annual shortage volume in meeting total demand in the months when total demand could not be met. Except for the most extreme climate conditions, average annual shortage volumes are small compared to the total demand of 40,629 AFY.

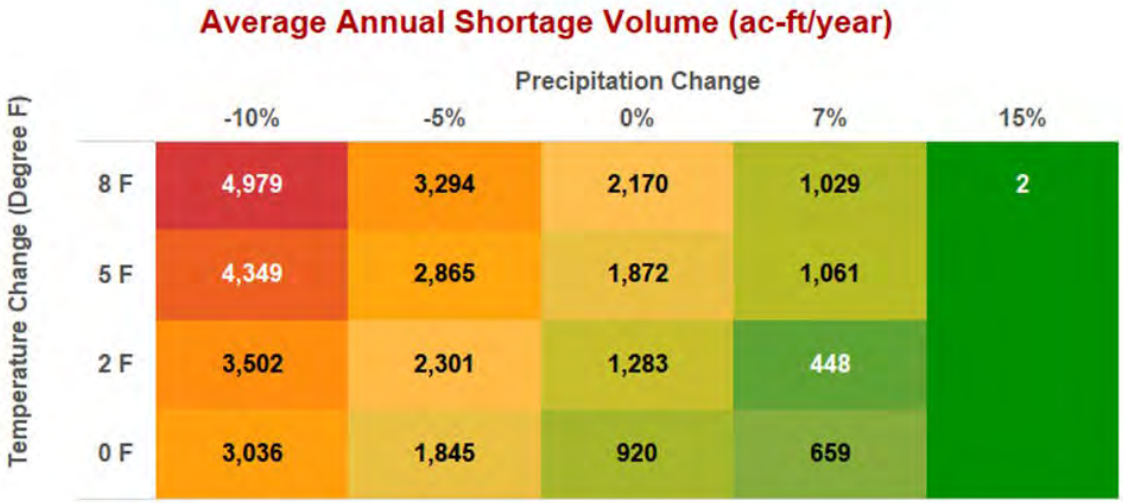

Figure 7-5 Average Annual Total Demand Shortage Volume for All Climate Conditions

Notes:

a) Blank, green cells had no shortages.

b) The value in each cell is the average annual shortage volume (difference between total annual demand and annual volume of water supplied) averaged across the 100 traces for the specified future climate condition.

FCU's Water Supply and Demand Management Policy requires at least 20% of annual demand be maintained in storage at all times for possible use in emergencies. **Figure 7-6** is a heat map for reliability of meeting the 20% storage reserve factor objective. It shows that with no changes in precipitation or temperature, the 20% storage reserve factor could be maintained in 97.1% of the simulated months across all 100 re-sequenced hydrologic traces. Any warmer or drier shift in climate from the 0/0 cell results in significant challenges in meeting the storage reserve factor policy. It is noted that these Climate Change Impact simulations assume the proposed Halligan Reservoir enlargement project is implemented. The effect of not enlarging Halligan Reservoir was investigated in the No Halligan Enlargement scenario, which is described in a following section.

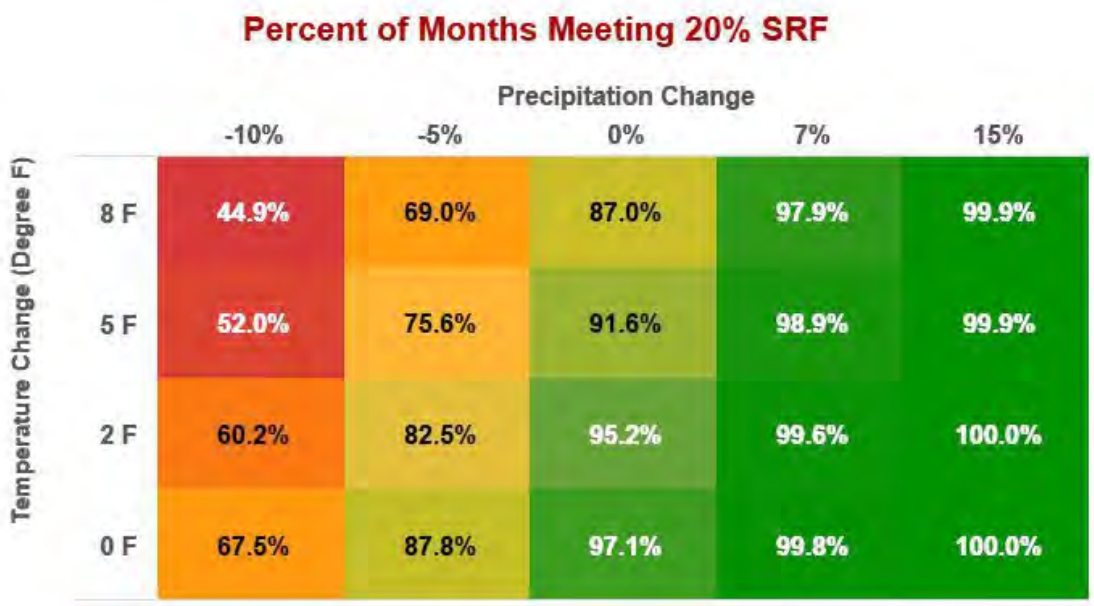

Figure 7-6. Average Monthly Reliability of Meeting 20% Storage Reserve Factor for All Climate Conditions

Although these Climate Change Impact simulations were performed without applying demand reductions due to implementing water use restrictions, the number of years in which restrictions would have been implemented according to FCU's Water Supply Shortage and Response Plan (City of Fort Collins, 2014) was calculated. The Plan has four levels of water use restrictions that are triggered based on the anticipated amount of supply shortage. The metric calculation counts all years when water use restrictions of any level would have been triggered. It represents times when one or more of the water supply planning policy criteria would not be met and FCU would have to implement some type of management response (e.g., water use restrictions, emergency supplies, other demand management strategies).

Figure 7-7 shows the average percent of years restrictions would have been activated for each climate combination. In this analysis water use restrictions are a surrogate for any operational measure implemented to respond to a water shortage condition. FCU could choose to implement other measures such as alternate operating strategies or acquisition of emergency supplies in lieu of declaring water use restrictions. The heat map in **Figure 7-7** shows that future climate has a significant effect on the frequency with which water use restrictions or other measures would be implemented. With baseline demands and no other risks applied, a 5 degree F warmer annual temperature and 5% less annual precipitation would require application of management measures in an average of 6 years in 10. In contrast, a future climate with 5-degree warmer annual temperature and 7% more annual precipitation would require application of management measures in an average of less than 1 year in 10.

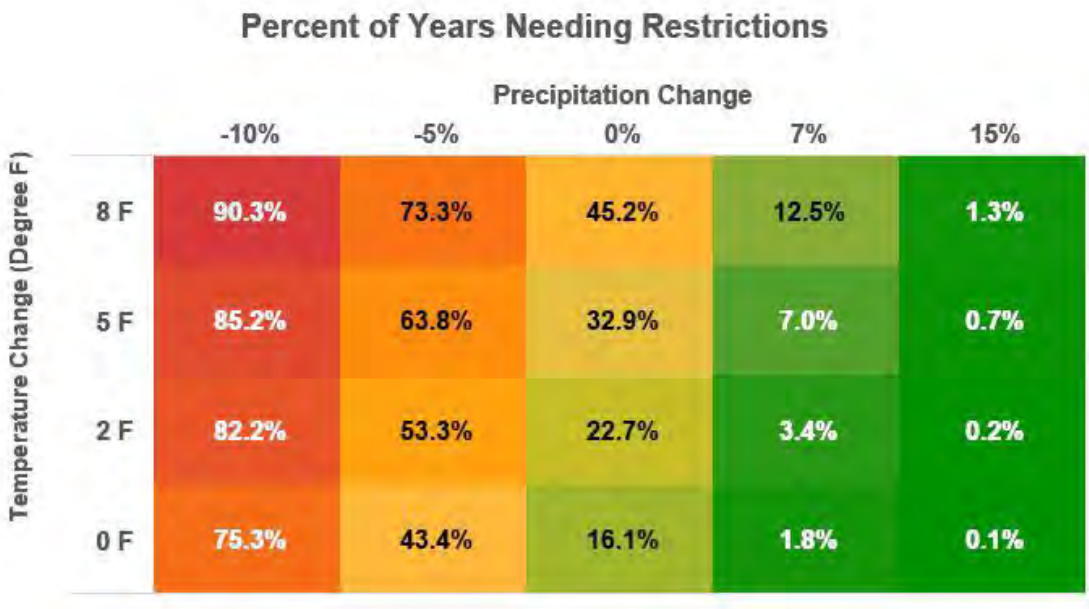

Figure 7-7 Average Percentage of Years During Which Water Use Restrictions Would Be Implemented Based on Current FCU Policy, for All Climate Conditions

Note: “Restrictions” is a surrogate for any demand management or emergency supply enhancement measures FCU would implement in response to potential violations of the water supply planning policy

As described in Section 2.2, failure to meet indoor demands with 100% reliability would have severe adverse public health and safety impacts on FCU customers. **Figure 7-8** shows that without any changes to temperature or precipitation, FCU can reliably meet indoor demands 99.8% of the time (2 months of shortage in 86 years when no restrictions are applied). In an extreme hotter and drier future, the reliability of meeting indoor demands drops to 83.5%.

Again, it is noted that all model simulations in the WSVS use full water demands in every year without application of water use restrictions. FCU would implement water use restrictions and other management measures long before indoor shortages would occur. Past experience has shown that customers in Fort Collins are capable of significantly reducing their water use in response to droughts or emergency conditions such as wildfires. Additional analysis will be needed to determine whether available management measures would be effective in eliminating the risk of indoor water demand shortages for the most severe future climate conditions.

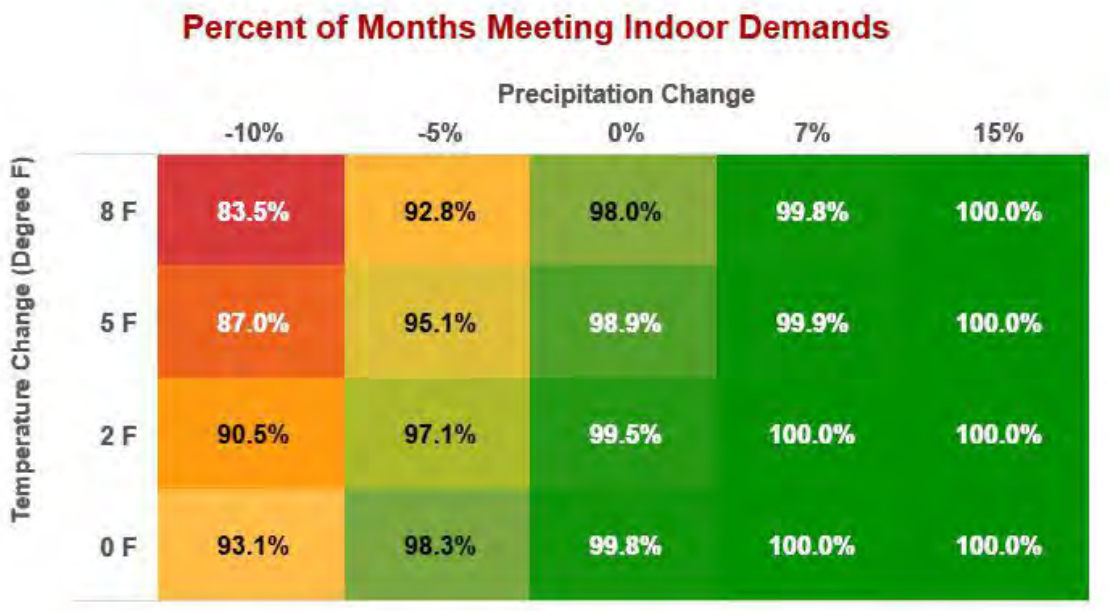

Figure 7-8 Average Indoor Demand Reliability for All Climate Conditions

7.3.2 Monthly Distribution of Shortage Periods

Figure 7-9 shows the 100-trace average count of monthly shortages. The upper plot is for the current climate conditions (T=0, P=0) and the lower plot is for the most severe climate condition (T=+8, P=-10). Note the scales of the two plots are different. In both climate conditions, the fewest number of shortages occur in the late spring and early summer months of May, June and July while storage is replenished and streamflows are the greatest. In the current climate conditions, shortages occur most often in March, April, September and October. These are shoulder seasons 1) before the spring runoff peaks when reservoir levels may still be low or 2) after the peak demands of summer have depleted reservoir storage levels. This pattern also appears in the most stressful climate future but is not as pronounced. The shortages are more evenly distributed over all months except than May and June because the stress of the climate provides little time to recover from a shortage.

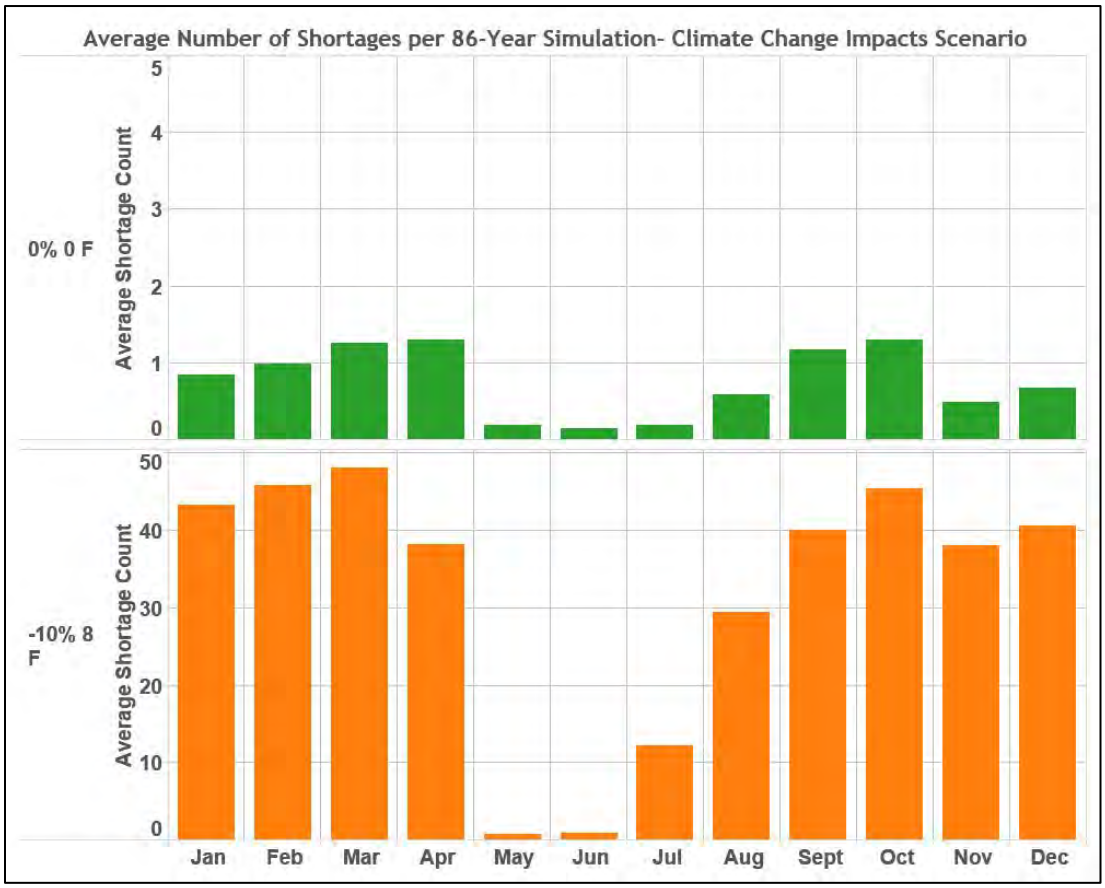

Figure 7-9 Average Monthly Distribution of Shortages for Climate Change Impacts Scenario

Notes:

a) The value in each bar is the average number of shortages in each month for an entire 86-year simulation period averaged across the 100 traces for the specified future climate condition.

b) The y-axis scales differ between the two plots.

7.3.3 Effect of Future Climate on C-BT Quota Calculated by CBTQ Model

The effects of climate change can be seen in the C-BT quotas estimated by the CBTQ model. C-BT quota is a direct output of the model. The C-BT quota determines the annual amount of water available to Fort Collins from the C-BT Project; this represents a significant source of supply to the FCU water resources system. Lower quotas mean less C-BT water is available to Fort Collins to supplement its local Poudre River supplies.

Figure 7-10 shows a series of box plots of the range of average quotas set for each of the 20 temperature and precipitation combinations. Each dot in the figure represents the average of the 86 annual quotas calculated for a single re-sequenced hydrology trace in the 86-year simulation period.

Figure 7-11 shows the variability and ranges of modeled quotas for four selected climates. The quota model produced a full range of quotas that have not been seen historically. Even for current conditions (0% precipitation and 0-degree temperature changes), the quota model produced some 10% quotas and 100% quotas.

For the current precipitation conditions (0% precipitation increase) and for drier climates (-5% and -10% precipitation), quotas tend to decrease as temperatures rise. However, for the much wetter condition (+15% precipitation), quotas tend to increase when temperatures rise. This is because the warmer temperatures create an increase in demand and the increase in precipitation augments supply such that a higher quota can be set. The average quota historically has been about 70%. The CBTQ model estimates quotas similar to the historical average for current and wetter future climates, but lower quotas (i.e., less C-BT supply for FCU) for drier future climates.

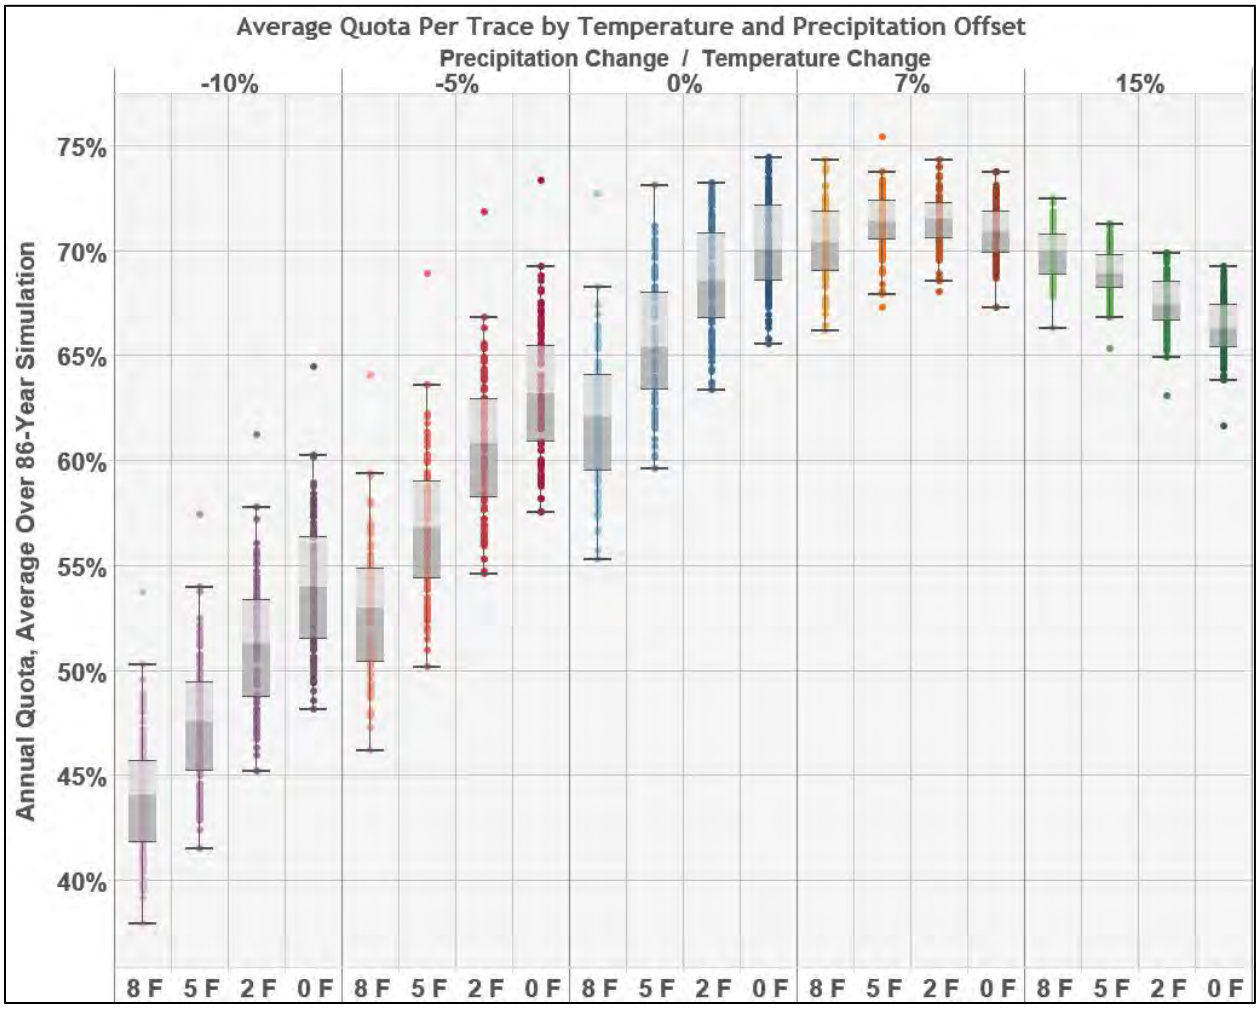

Figure 7-10 Annual C-BT Quota from CBTQ Model by Temperature and Precipitation Offset, Averaged over 86 Years for Baseline Scenario

Notes:

a) Poorer performance indicated by lower quota towards bottom of graph.
b) Each dot is the average of the annual quotas for an 86-year hydrologic trace. 100 traces (dots) are shown in each box plot.
c) Average quota historically is 70%.

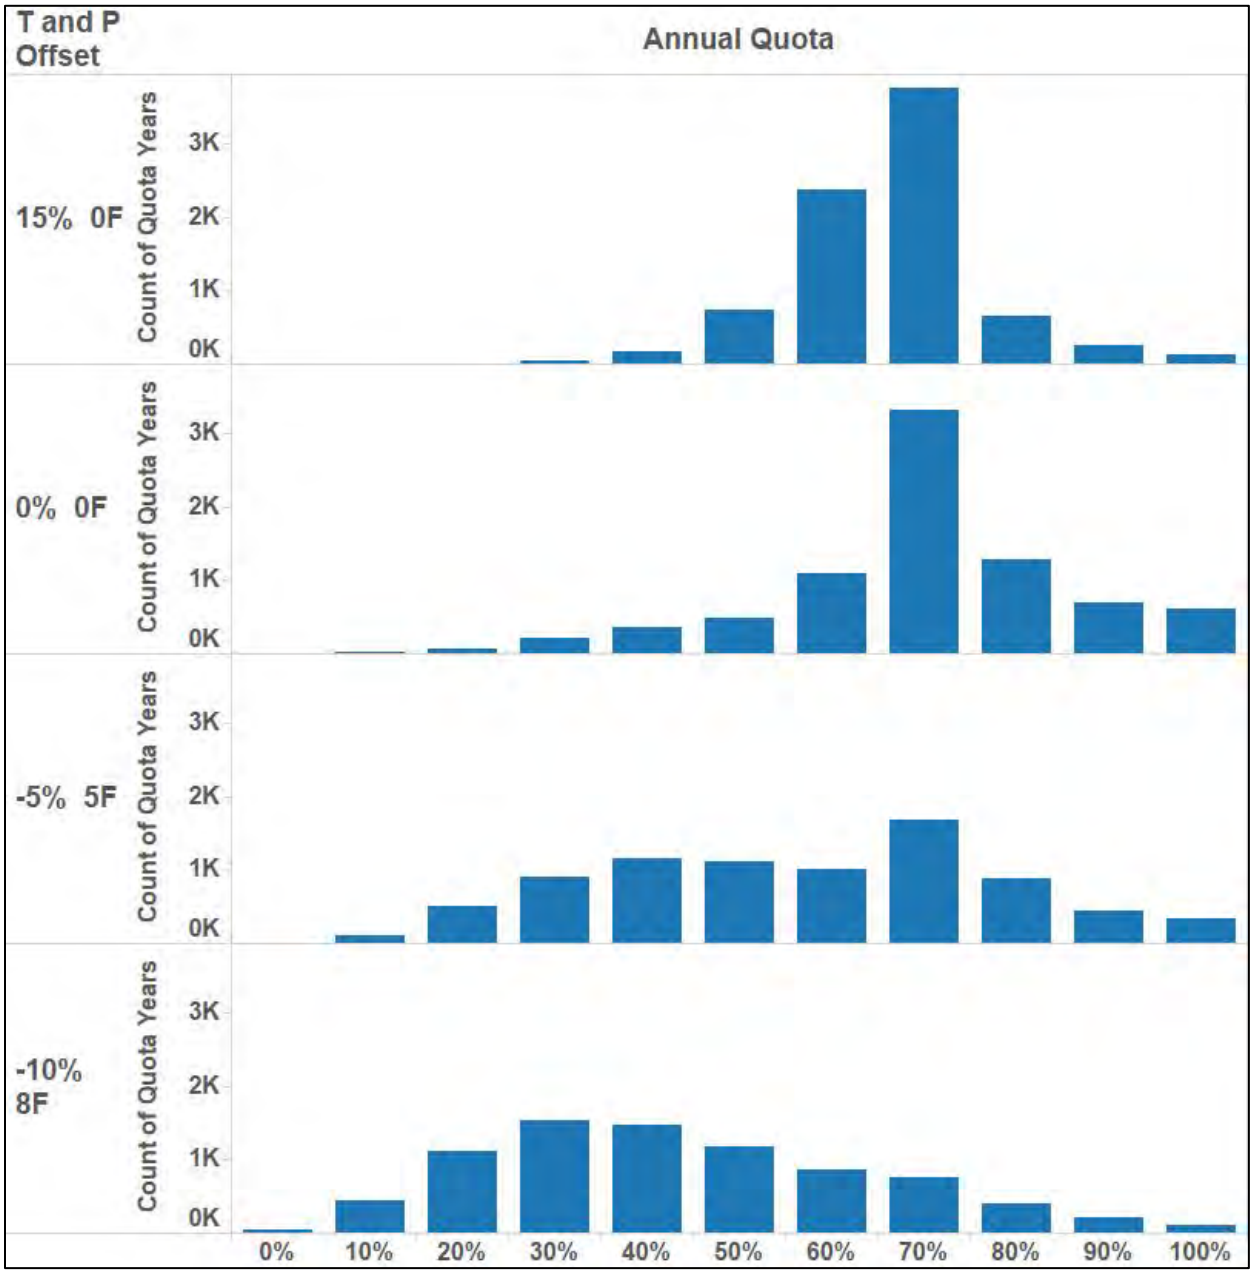

Figure 7-11 Range and Variability of Annual Quotas for all Traces and Selected Climates

Notes:

a) Each bar sums the number of times each Quota percentage was set for all 100 traces of the selected climate offsets.

b) Selected climates get warmer and drier with each plot moving down

7.4 DEMAND VULNERABILITY RESULTS

The Increased Demands Scenario was simulated to assess the sensitivity of the FCU water resources system to variable demands in 2070 which incorporate climate variability, some of which are an increase over the baseline water demand. This scenario includes the three demand scenarios described in Section 4 – City Plan 2, City Plan 3 and City Plan 3 Plus 20%. **Table 7-1** summarizes the average annual demands for the future conditions evaluated in the Increased Demands Scenario.

The Increased Demands Scenario does not include additional system risks. Each demand scenario was simulated for all 100 hydrologic traces for each of the 20 temperature and precipitation climate combinations. As described in Section 4, model simulations apply the same demand assumptions for all 86 years of the simulation period. That is, all years in the model represent the future 2070 condition described by the assumed demand scenario. The WSVS simulations do not account for a gradual increase in demand over time but focus only on the future condition. Additional analysis would be needed to evaluate FCU water system performance in intermediate years between current conditions and 2070.

Table 7-1 Summary of Average Annual 2070 Demands for Demand Scenarios

Demand Scenario	2070 Population	Minimum Average Annual Demand for 86-Year Simulation for Current Climate Conditions (AFY)	Median Average Annual Demand for 86-Year Simulation for Current Climate Conditions (AFY)	Maximum Average Annual Demand for 86-Year Simulation for Current Climate Conditions (AFY)
Baseline	179,000		40,629[(a)]	
City Plan 2	178,000	36,171	37,687	39,511
City Plan 3	195,000	37,664	38,215	41,081
City Plan 3 + 20%	234,000[(b)]	43,333	45,194	47,433

Notes:
a) Not based on application of Demand Estimation Tool or 86-year simulation. Included for comparison to previous studies.
b) Population is 20% increase over City Plan 3 population. This demand scenario incorporates other factors besides population increase, so all demand increase compared to City Plan 3 demand may not be due to population increase.

Results of the modeling for the Increased Demands Scenario are shown in the parallel line plots below (**Figure 7-12** through **Figure 7-14**). These plots show the values of the specified metric for the three demand scenarios as a function of temperature across the range of change in average annual precipitation. Each set of lines applies to one of the values for the assumed change in precipitation. Within a precipitation column, temperature decreases (i.e., improves in terms of influence on water supply) from left to right. The upper panel y-axis shows the average annual demand shortage in acre-feet per year only during times of shortage. Lines that rise to the top of the graph have worse system performance as they show more demand shortage over the simulation. The lower y-axis shows the average number of years with shortages. Lines that rise to the top of the graph have worse system performance because more of the years have shortages.

Key results from the analysis of the Increased Demands Scenario are summarized below.

- Results for each of the metrics show similar trends. This simplifies the interpretation of results and suggests FCU could select the most convenient or best-understood metric to assess relative system response to future demand increases.

- The City Plan 2 and City Plan 3 scenarios result in very similar system performance across the range of climate conditions in the WSVS. This indicates City planning decisions affecting growth within the range encompassed by these two scenarios will have only minor impacts on total water demand, although they could play a significant role in reducing per capita water demand.

- Under City Plan 2 and City Plan 3, the current water supply planning policy criteria (no shortages, no water use restrictions and 20% storage reserve factor at all times) can only be satisfied for the wettest future climate (+15% precipitation). For a moderate climate change condition (T=+5, P=-5%), additional supply or demand management measures would be required in about 23% of years (20 out of 86) and would need to make up for an average annual shortage volume in those years of about 2,500 AFY (**Figure 7-12**). For the same moderate climate change condition, the storage reserve factor would fail to be maintained in about 20% of months (**Figure 7-13**), putting FCU water supply at greater risk under emergency conditions. If management measures were not implemented, the FCU system would be in a condition when water restrictions would be declared under the current water supply policy in about 6 years in 10 (**Figure 7-14**).

- The City Plan 3 Plus 20% demand condition, which assesses an unanticipated future demand increase, results in significantly worse performance than the City Plan 3 condition. Current water supply planning policy criteria could not be satisfied under any future climate condition simulated for the WSVS. For a moderate climate change condition (T=+5, P=-5%), if management measures were not implemented, the FCU system would be in a condition when water restrictions would be declared under the current water supply policy in about 8 years in 10.

- Without the 20% demand increase, the City Plan 2 and City Plan 3 showed the FCU system would perform well in the future at current or wetter precipitation conditions and no changes in temperature. When temperatures rise or precipitation decreases, system performance decreases.

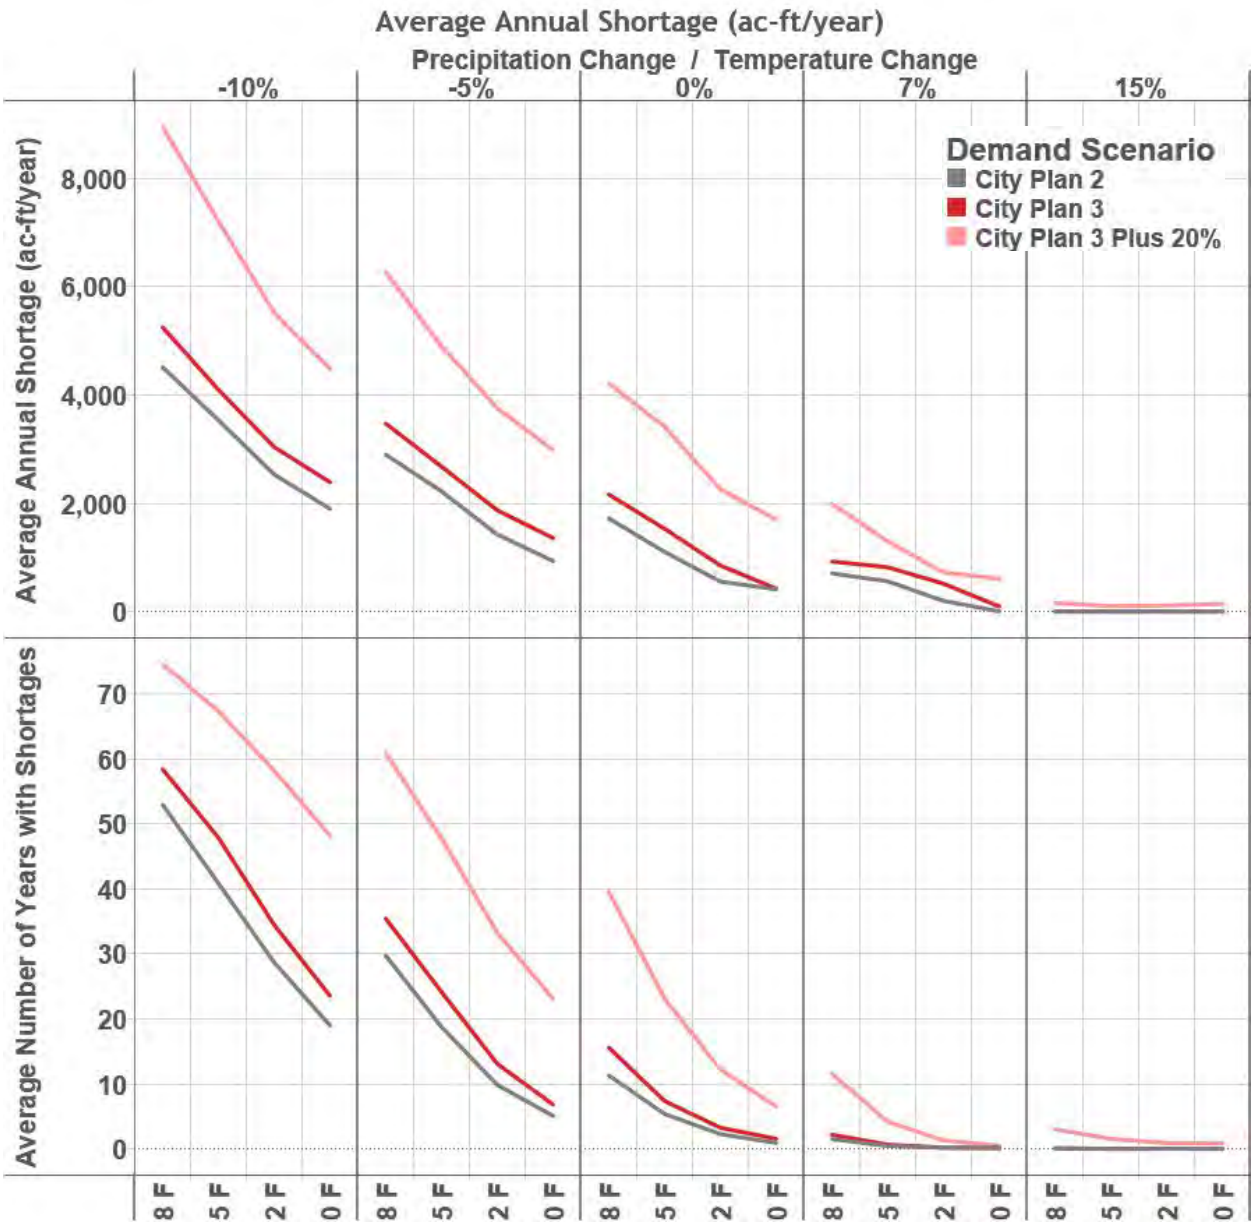

Figure 7-12 Average Annual Total Demand Shortage for Increasing Demand Scenarios and All Climate Conditions

Notes:

a) Demands represent 2070 population and development conditions.
b) Average annual shortage metric is calculated as the sum of annual shortages over the 86-year simulation period divided by the number of years when shortages occurred.
c) Average number of years with shortage is based on 86 years in the model simulation period.
d) Poorer performance indicated by greater shortage towards top of graph.

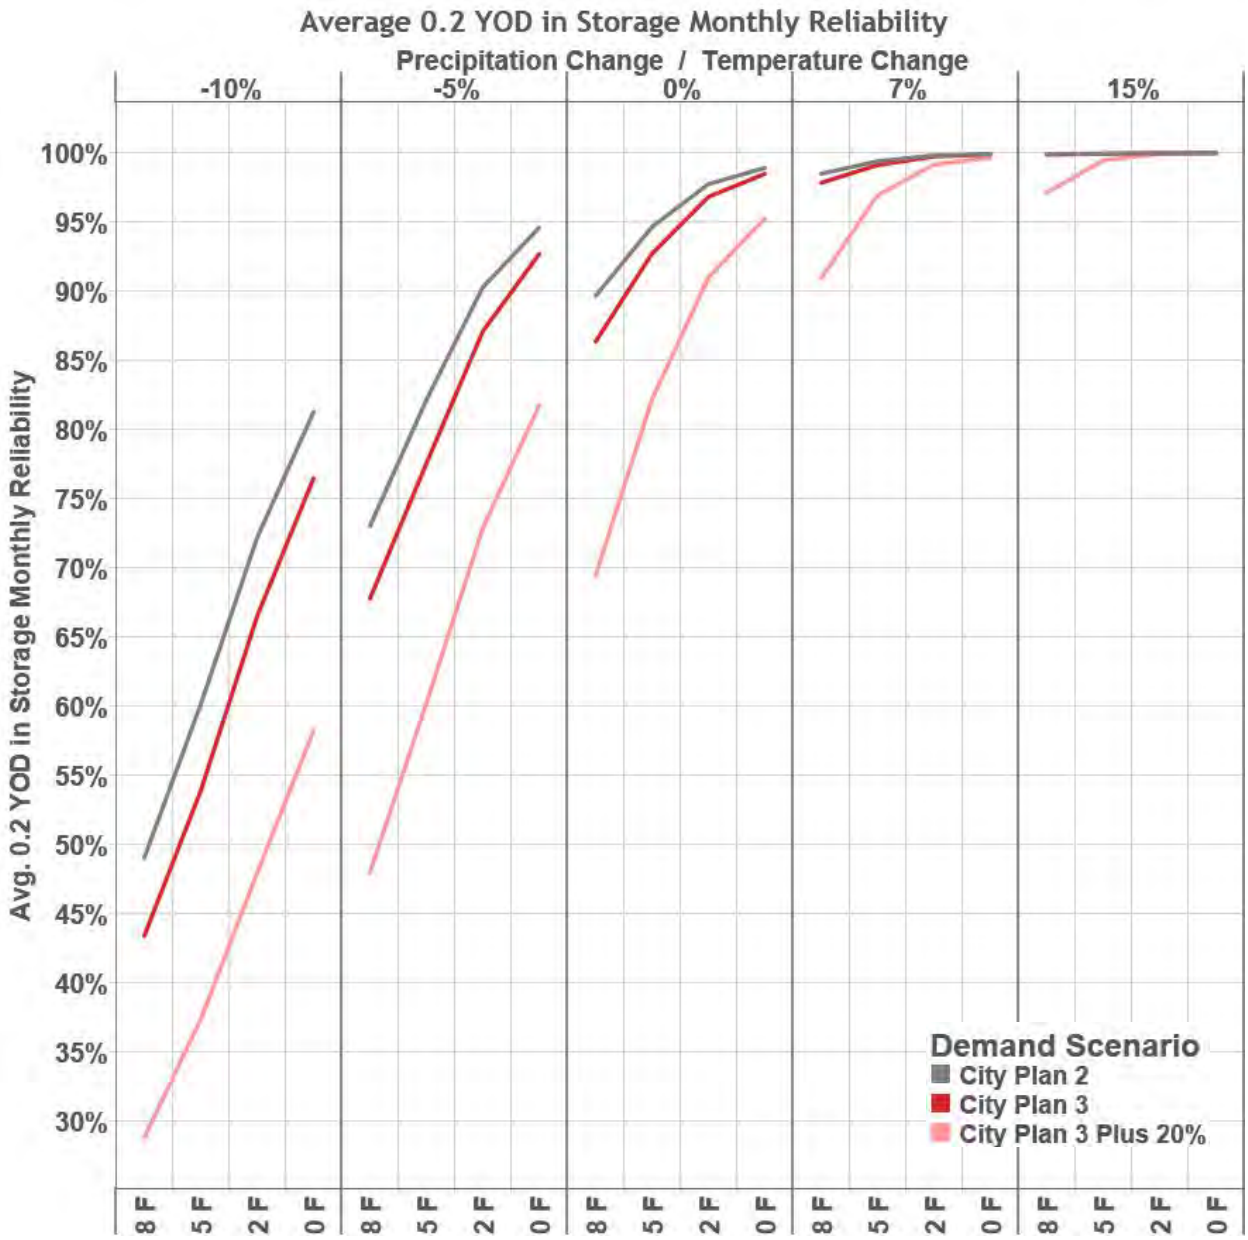

Figure 7-13 Average Monthly Reliability of Meeting 20% Storage Reserve Factor for Increased Demands Scenario and All Climate Conditions

Notes:

a) Demands represent 2070 population and development conditions.
b) Poorer performance indicated by lower reliability towards bottom of graph.

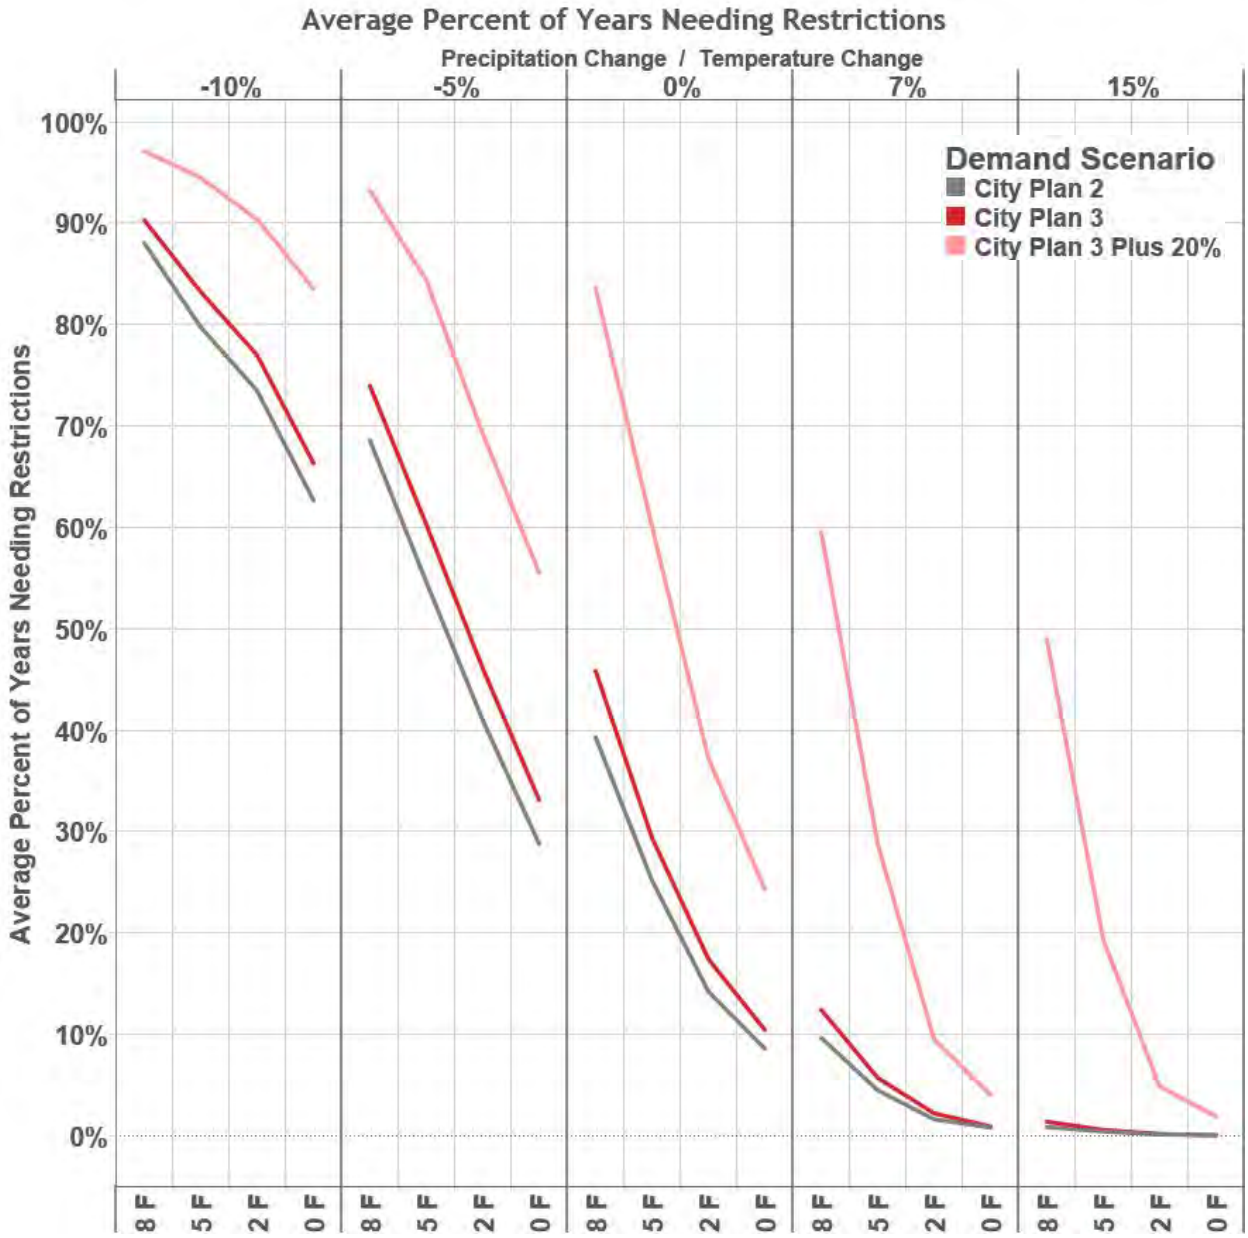

Figure 7-14 Average Percent of Years When Water Use Restrictions Would be Declared for Increased Demands Scenario

Notes:

a) Demands represent 2070 population and development conditions.
b) Poorer performance indicated by more restriction need towards top of graph
c) "Restrictions" is a surrogate for any demand management or emergency supply enhancement measures FCU would implement in response to potential violations of the water supply planning policy

Any values of indoor demand reliability less than 100% suggest potential critical conditions. **Figure 7-15** shows that under all climate conditions except 7% and 15% increase in precipitation, all three demand scenarios could create risks for the current FCU water resources system if demand management measures were not implemented. FCU would aggressively implement demand management or emergency supply measures if there was threat of not meeting all indoor demands. For example, indoor demand reliability would be greatly improved by implementing water use restrictions that reduce outdoor demand in summer and preserve more water in storage for use in meeting indoor demands in winter before the next runoff period.

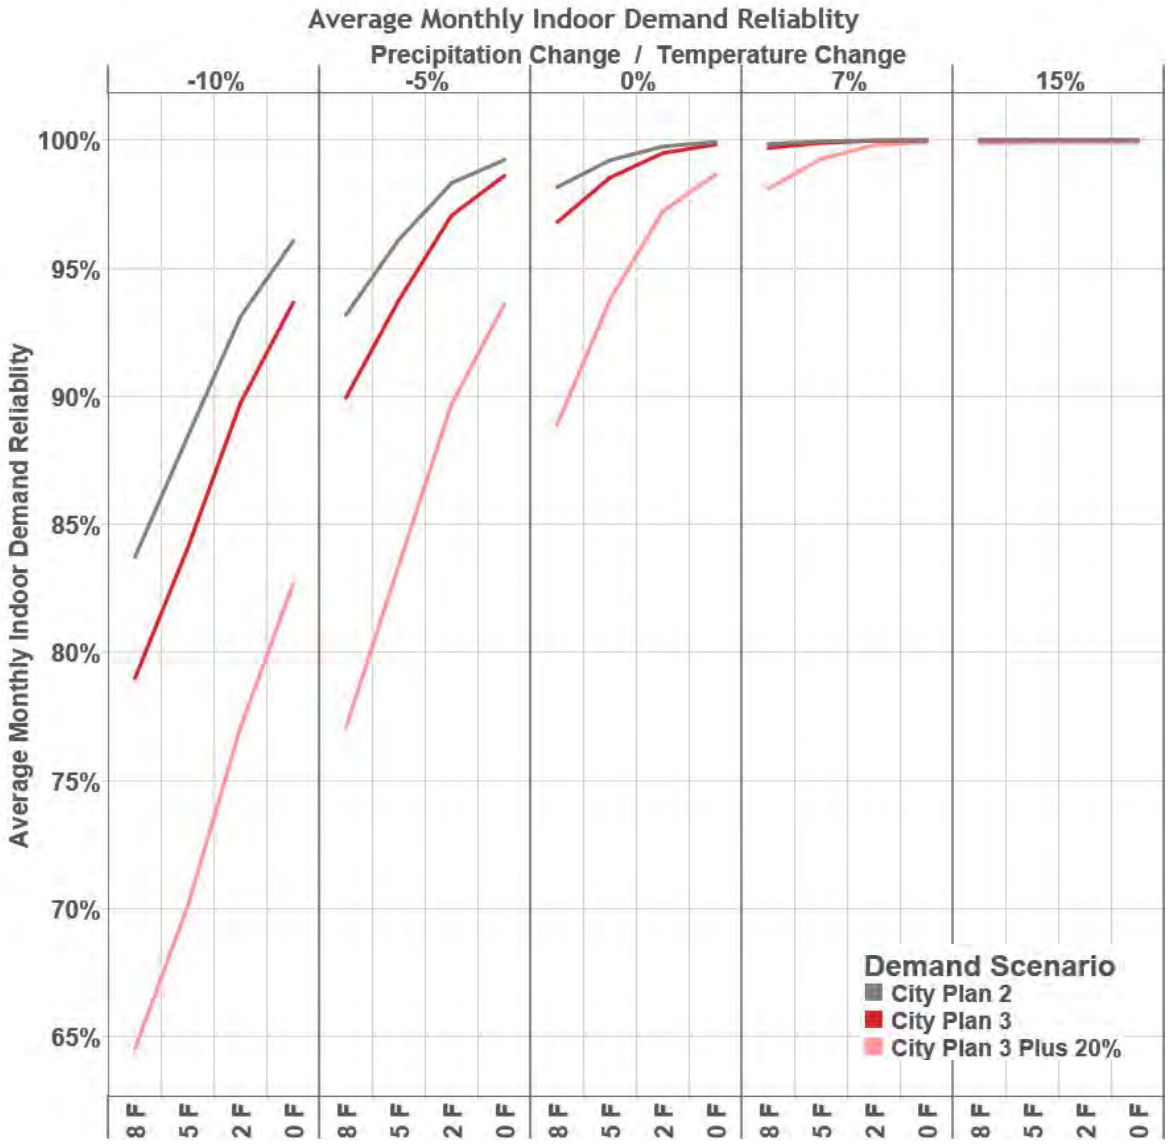

Figure 7-15 Average Monthly Indoor Demand Reliability for Increased Demands Scenario

Notes:

a) Demands represent 2070 population and development conditions.
b) Poorer performance indicated by lower reliability towards bottom of graph.

Due to the way the City Plan 3 scenario was developed, it represents the most reasonable upper bound for future demands based on current expected growth patterns and trajectories. Therefore, results of the vulnerability simulations for the City Plan 3 demand scenario at 0 temperature and precipitation change (0/0) can be considered a reasonable basis to compare the effects of the demand risks to the effects of climate change uncertainty. **Table 7-2** compares the influence of demand increases under current climate with the influence of climate change under baseline demands for four selected metrics related to the current water supply planning policy criteria. Results show that over the range of future climate and demand conditions considered in the WSVS, modest climate change and modest demand increases have similar impacts on the ability to meet the water supply policy criteria. However, the most severe climate change condition will create greater challenges for meeting the current policy criteria than the highest future demand forecast.

Table 7-2 Comparison of Influence of Demand Increases Under Current Climate with Influence of Climate Change Under Baseline Demand

Climate/Demand Condition	Average Number of Years When Total Demand is Not Met	Average Annual Demand Shortage in Years When Shortages Occur	Average Number of Months when 20% Storage Reserve Factor is Not Met	Average Percentage of Years in Restrictions if No Management Measures are Implemented
Current Climate [(a)]				
City Plan 2 Demand	1	412 AFY	11	7
City Plan 3 Demand	2	424 AFY	15	9
City Plan 3 + 20% Demand	6	1,700 AFY	49	21
Constant Annual Demand [(b)]				
T=0, P=+15 Climate	0	0 AFY	0	0
T=0, P=0 Climate	3	920 AFY	30	14
T=+5, P=-5% Climate	27	2,865 AFY	252	55
T=+8, P=-10% Climate	58	4,979 AFY	569	78

Notes:
a) Current Climate: Demands vary annually based on each trace. Results are averaged over all 100 traces for climate T=0, P=0
b) Baseline Demand: Demands are constant between years. Results are averaged over all 100 traces for climate scenarios listed

7.5 RISK SCENARIO RESULTS

Each of the identified vulnerability scenarios from Section 6 were run for the City Plan 2 and City Plan 3 demand levels for all hydrologic traces and climate combinations. Exceptions are the baseline simulation, which was run for a constant demand and historical climate only; the Climate Change Impacts scenario, which was run for constant demand only; and the Increased Demands scenario, which was run for the two City Plan demand levels plus the City Plan Plus 20% demand described above. The results shown in this section, unless otherwise noted, are for the City Plan 3 demand scenario. Results with the City Plan 2 demand scenario are similar but have slightly better metric values than the results with the City Plan 3 demand scenario.

The discussion of the risk scenarios is organized around a series of key metrics. Performance of the scenarios based on each metric is discussed, then the scenarios are compared according to the overall vulnerability they pose to the Fort Collins raw water system.

7.5.1 Comparison of Scenarios Based on the Average Annual Demand Shortage Metric

Figure 7-16 compares system performance for all the scenarios based on the average annual demand shortage metric. This metric is calculated for a given model run by summing the volume of the demand shortage (difference between the volume of total annual demand and actual volume of water supplied in each year) across the full 86-year simulation period and dividing by the number of years in which demand shortages occur. Results are displayed as parallel line plots. Each set of lines applies to one of the values for the assumed change in precipitation. Within a precipitation column, temperature decreases (i.e., improves in terms of influence on water supply) from left to right. The upper panel y-axis shows the average annual demand shortage in acre-feet per year only during times of shortage. The lower y-axis shows the average number of years with shortages.

Parallel line plots are effective in displaying the relative performance of all the risk scenarios across the range of climate conditions simulated in the WSVS. As expected, the greatest annual shortages for nearly every risk scenario are seen in simulations with lower precipitation. Greater precipitation can lessen the effects of the risks on FCU's water supply system despite warming temperatures. Most of the risk scenarios have a similar impact on the average annual shortage metric, as future climate temperature and precipitation change. The exception is some of the short-term risk scenarios for wetter future climates; these anomalies are discussed in a following section.

The risk scenario with the greatest average annual demand shortage is the Increased Demands Scenario (City Plan 3 Plus 20%) for simulations with reduced precipitation. Other scenarios that perform poorly for drier conditions are the Loss of Storage Scenario (no Halligan Reservoir enlargement and no C-BT carryover storage in Horsetooth Reservoir) and the Reuse Plan Change 1 Scenario (elimination of Reuse Plan). In scenarios with greater precipitation, the Poudre River System – Environmental Impacts Scenario has the greatest average annual demand shortage. This scenario simulates the effects of algal blooms and wildfires by eliminating the use of water from Horsetooth Reservoir for one year and preventing full use of the water supply pipelines from the Poudre River for 10 years.

The following plots and paragraphs discuss results for several categories of similar risk scenarios.

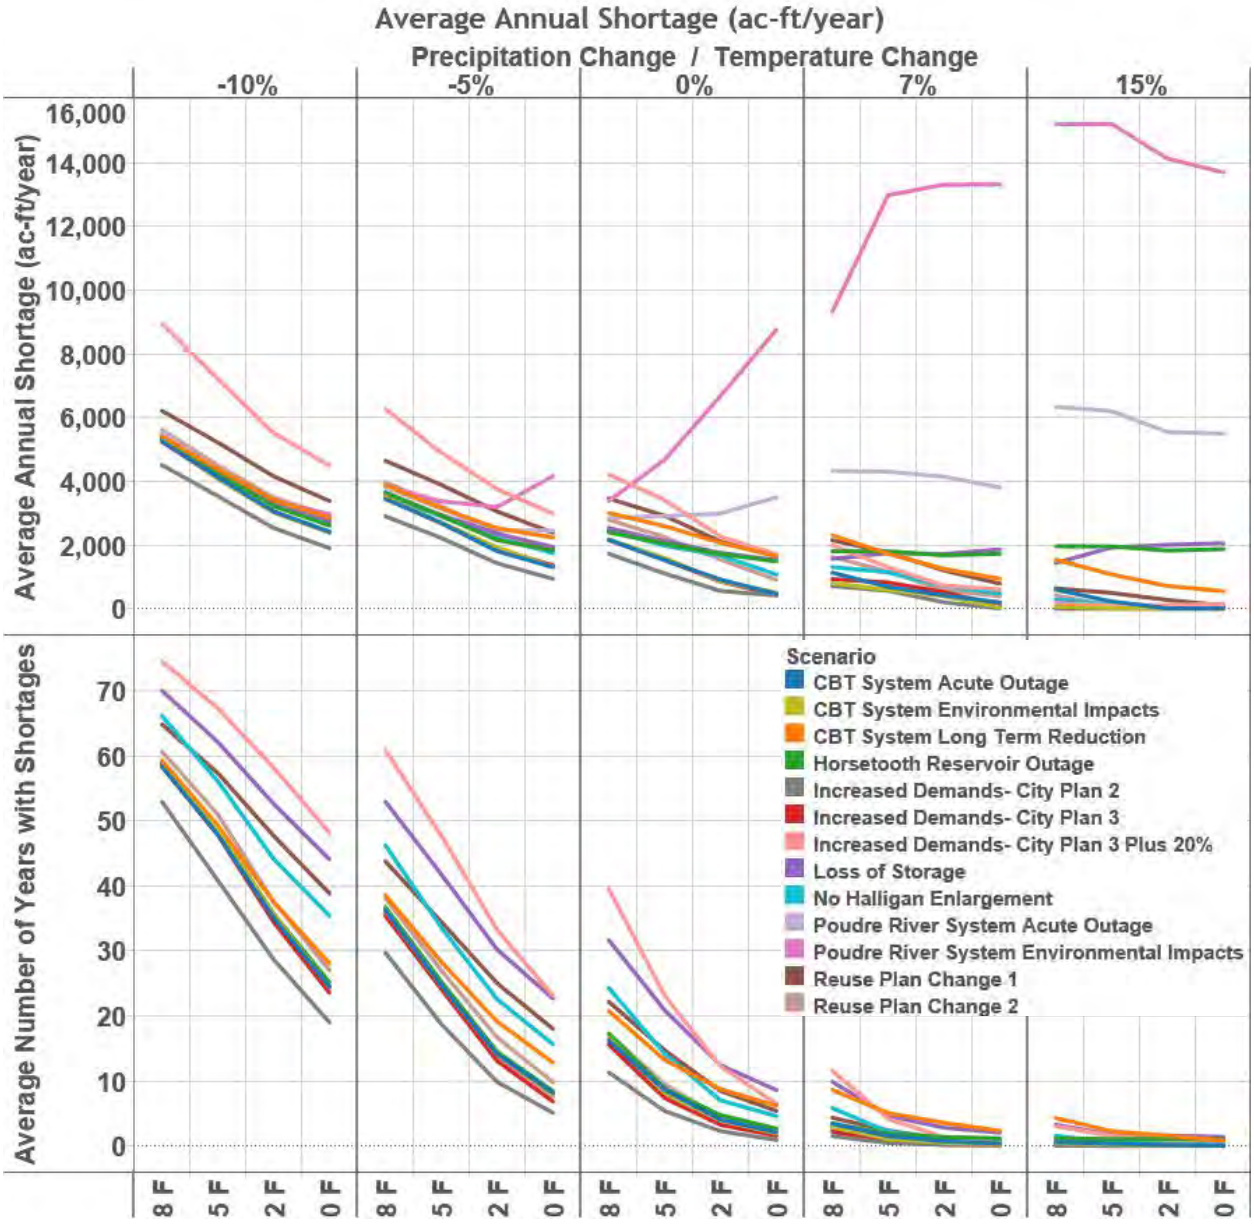

Figure 7-16 Average Annual Shortage and Number of Years with Shortages - All Scenarios

Notes:

a) Average annual shortage metric is calculated as the sum of annual shortages over the 86-year simulation period divided by the number of years when shortages occurred.
b) Average number of years with shortage is based on 86 years in the model simulation period.
c) Poorer performance indicated by greater shortages towards top of graph.

Figure 7-17 shows the average annual demand shortage for the two reuse plan scenarios. Reuse Plan Change 1 eliminates the reuse plan for the entire simulation period whereas Reuse Plan Change 2 reduces the reuse plan by 50% for the entire simulation period. Again, during simulations with increased precipitation, the average annual demand shortage is low, while simulations with decreased precipitation show higher annual demand shortages. This is particularly true when the reuse plan is eliminated in the Reuse Plan Change 1 scenario. Comparison with other scenarios shows that reductions to, or elimination of the reuse plan are some of the more potentially impactful risks evaluated in the WSVS.

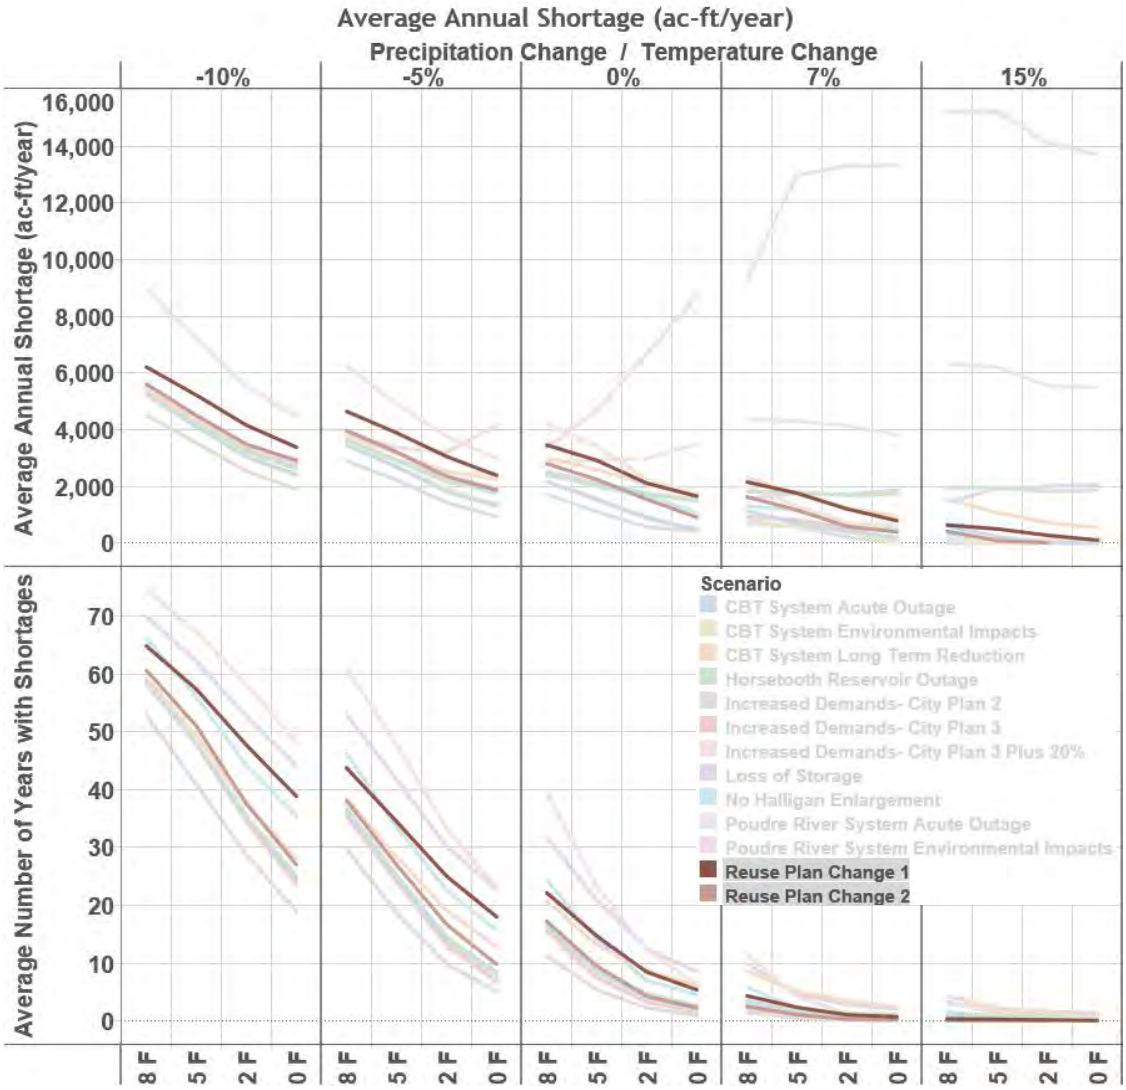

Figure 7-17 Average Annual Shortage and Number of Years with Shortage - Reuse Plan Change Scenarios

Notes:

a) Average annual shortage metric is calculated as the sum of annual shortages over the 86-year simulation period divided by the number of years when shortages occurred.
b) Average number of years with shortage is based on 86 years in the model simulation period.
c) Poorer performance indicated by greater shortages towards top of graph

Figure 7-18 shows the average annual shortage metric for the No Halligan Expansion scenario and the Loss of Storage Scenario. As shown, unless there is an increase in precipitation, there are significant shortages in meeting the future demand. The Loss of Storage scenario combines the risk of not having the Halligan Expansion with the risk of not being able to use C-BT carryover storage in Horsetooth Reservoir. Without the ability to use these two storage facilities, overall annual demands cannot be met. These scenarios demonstrate the importance of storage to FCU's system.

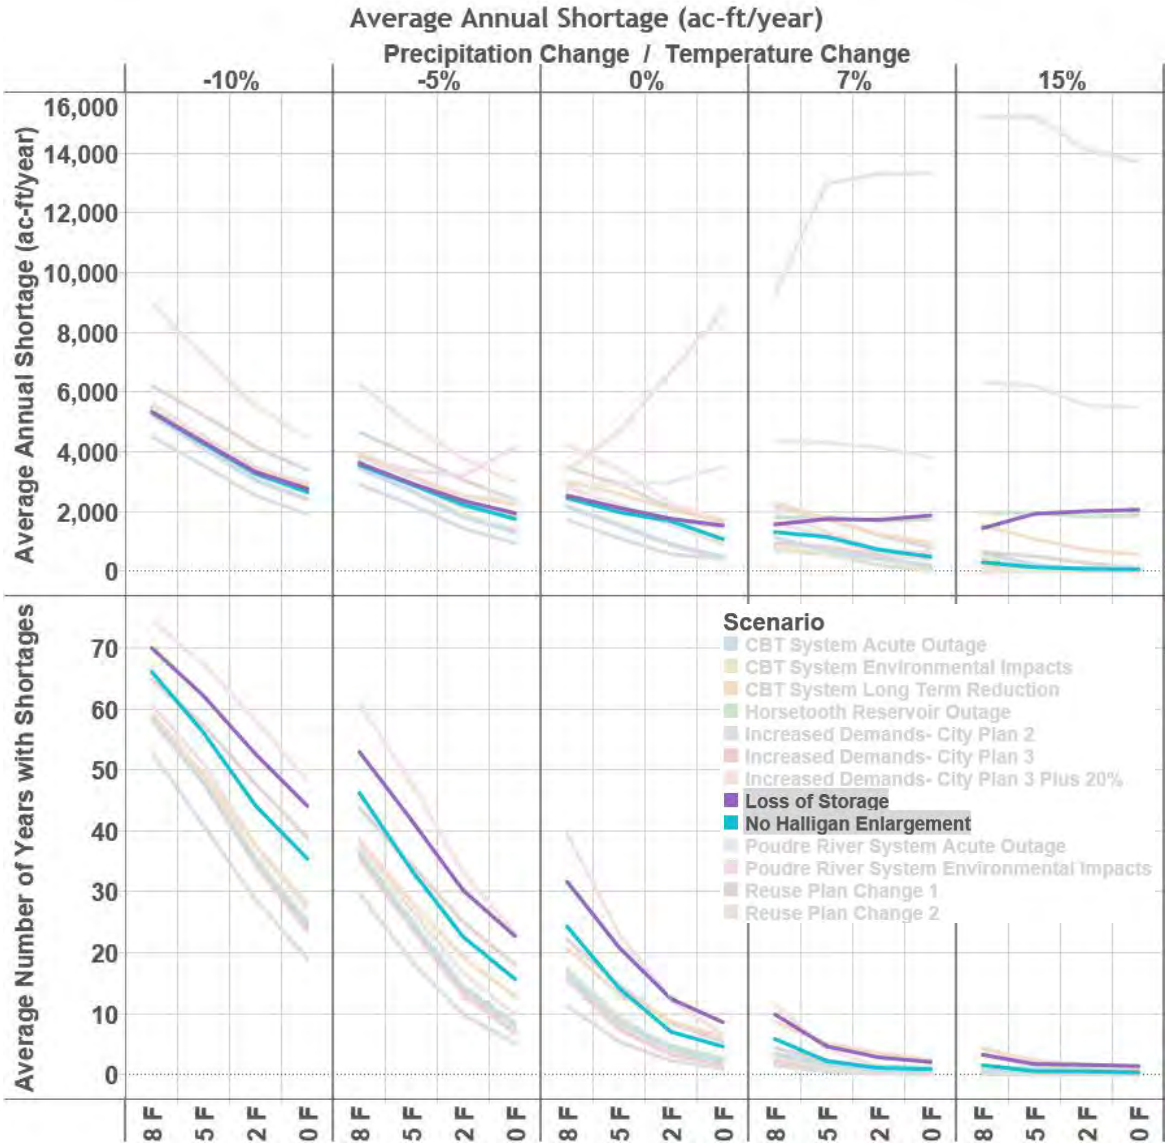

Figure 7-18 Average Annual Shortage and Number of Years With Shortage - Loss of Storage and No Halligan Enlargement Scenarios

Notes:

a) Average annual shortage metric is calculated as the sum of annual shortages over the 86-year simulation period divided by the number of years when shortages occurred.
b) Average number of years with shortage is based on 86 years in the model simulation period.
c) Poorer performance indicated by greater shortages towards top of graph

Figure 7-19 shows results for the C-BT System Long Term Reduction Scenario. In this scenario, the C-BT Quota is set to 25% for 10 years following a randomly selected dry year. This scenario shows more shortages than many of the other scenarios in both wet and dry years. As described in Section 1.2, FCU receives approximately half of its water supply from the Poudre River and half from the C-BT and/or Windy Gap Projects, on an annual basis. Therefore, it is logical that the very low quota simulated in this scenario would impact FCU's ability to meet demands, regardless of the climate conditions.

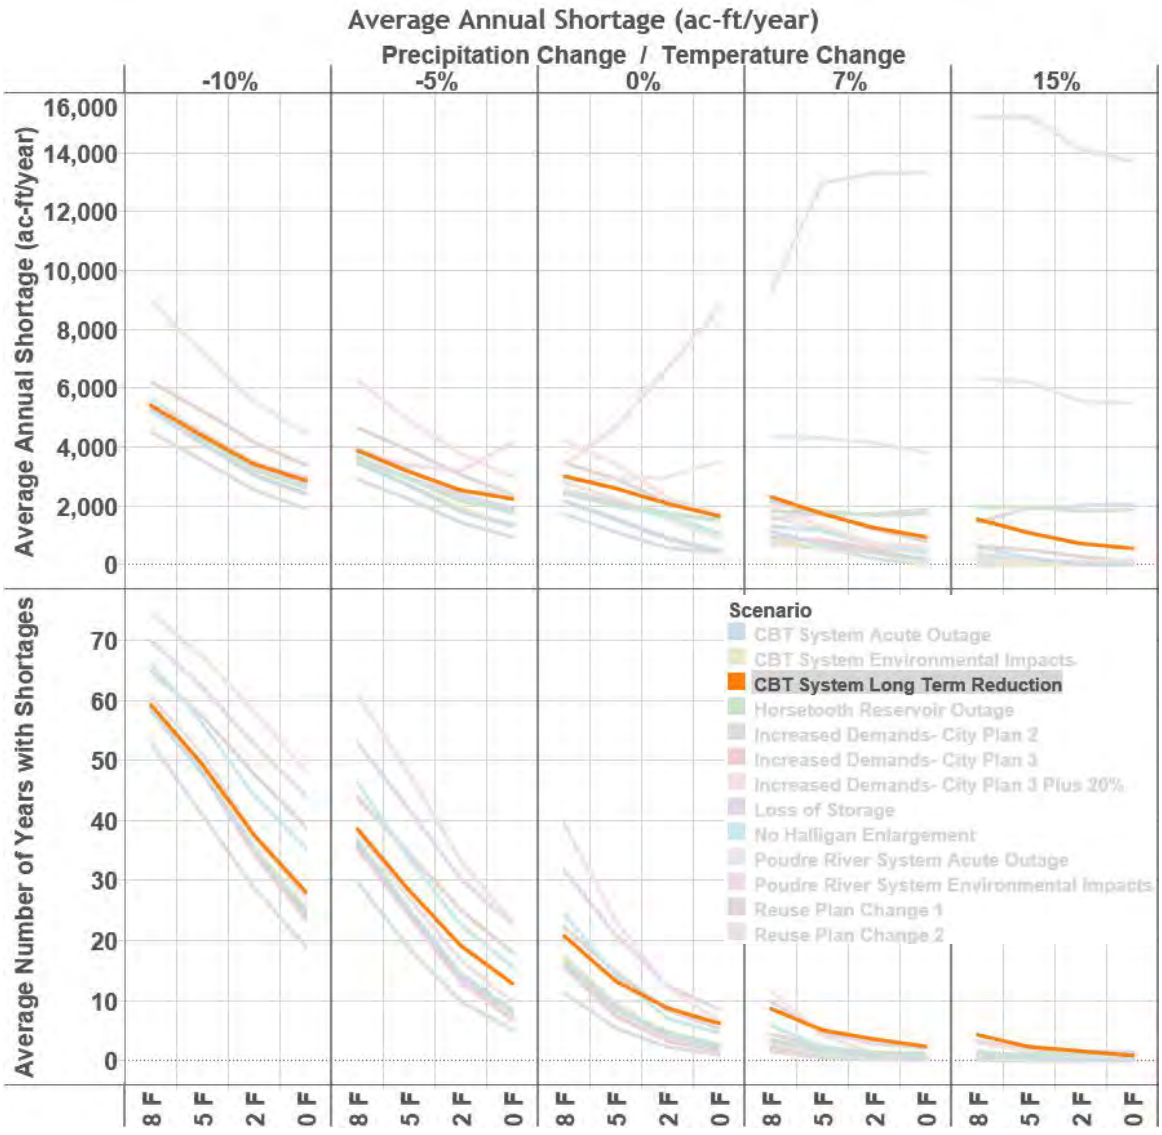

Figure 7-19 Average Annual Shortage and Number of Years With Shortage – C-BT Long Term Reduction Scenario

Notes:

a) Average annual shortage metric is calculated as the sum of annual shortages over the 86-year simulation period divided by the number of years when shortages occurred.
b) Average number of years with shortage is based on 86 years in the model simulation period.
c) Poorer performance indicated by greater shortages towards top of graph

Figure 7-20 shows results for the two Poudre River short-term outages. The average annual shortage increases substantially for the wetter climates because the number of years with shortages due to climate influence decreases. These short-term risks, associated with infrastructure outages or water quality degradation, occur for only a few months during the 86-year simulation period, so effects on system performance are relatively brief but severe. This generates a high value for the average annual shortage metric. The comparison in the figure demonstrates the fundamental difference in FCU water resources system response to short-term vs long-term risks. Because all other metrics are calculated over the entire 86-year simulation period they are not effective in isolating effects of short-term risks. Additional analysis will be required to more fully understand effects of short-term risks on system performance.

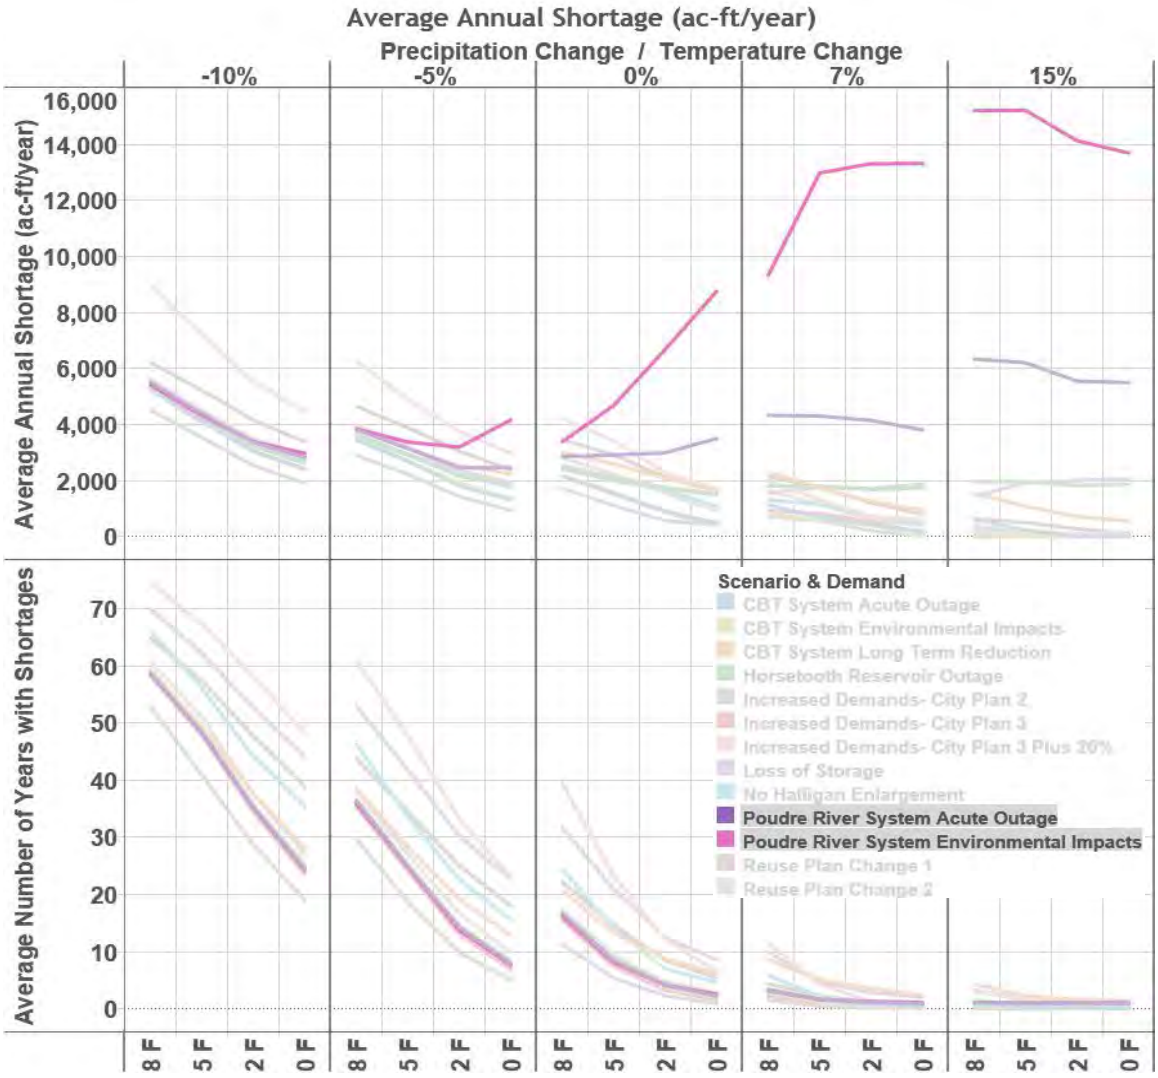

Figure 7-20 Average Annual Shortage and Number of Years with Shortages - Poudre River Short Term Risks

Notes:

a) Average annual shortage metric is calculated as the sum of annual shortages over the 86-year simulation period divided by the number of years when shortages occurred.
b) Average number of years with shortage is based on 86 years in the model simulation period.
c) Poorer performance indicated by greater shortages towards top of graph.

7.5.2 Comparison of Scenarios for the Storage Reserve Factor Metric

The next set of parallel line graphs, starting with **Figure 7-21**, depict the performance of the scenarios with respect to the reliability of maintaining 20% of the annual demand in storage as a storage reserve factor (SRF). The SRF typically equates to about 1.5 months of summer demands or 4 months of winter demands. The current water supply planning policy sets the SRF target of 20% of annual demand at 100% reliability (i.e., at all times) as insurance against unforeseen future conditions or emergencies. For this metric, scenario lines at the bottom of the graph have worse performance as they are less often able to maintain the 20% SRF.

The 20% SRF reliability metric behaves similarly for all the risks scenarios as the assumed future climate is varied. As was the case with the average annual shortage metric, the scenarios with the worst performance for the 20% SRF metric are the City Plan + 20% demands, the changes to the reuse plan, Loss of Storage and No Halligan Enlargement and the C-BT Long-Term Reduction.

The water supply planning policy goal of 20% SRF with 100% reliability cannot be met for any of the risk scenarios, with the exception of some short-term risks and the City Plan 2 demand scenario under the wettest and coolest climate conditions. Under nearly all future conditions, FCU would have to implement water supply enhancement or demand management measures to maintain the 20% SRF reliability goal at all times. Under the most severe climate condition (T=8, P=-10%), the 20% SRF goal can be met only 30% to 50% of the time across the range of risk scenarios. It is expected that significant water resources system improvements, likely consisting of additional storage, would be needed to maintain the 20% SRF goal for any of the WSVS risk scenarios in this severe climate condition.

Results for categories of similar risk scenarios are described in the following paragraphs.

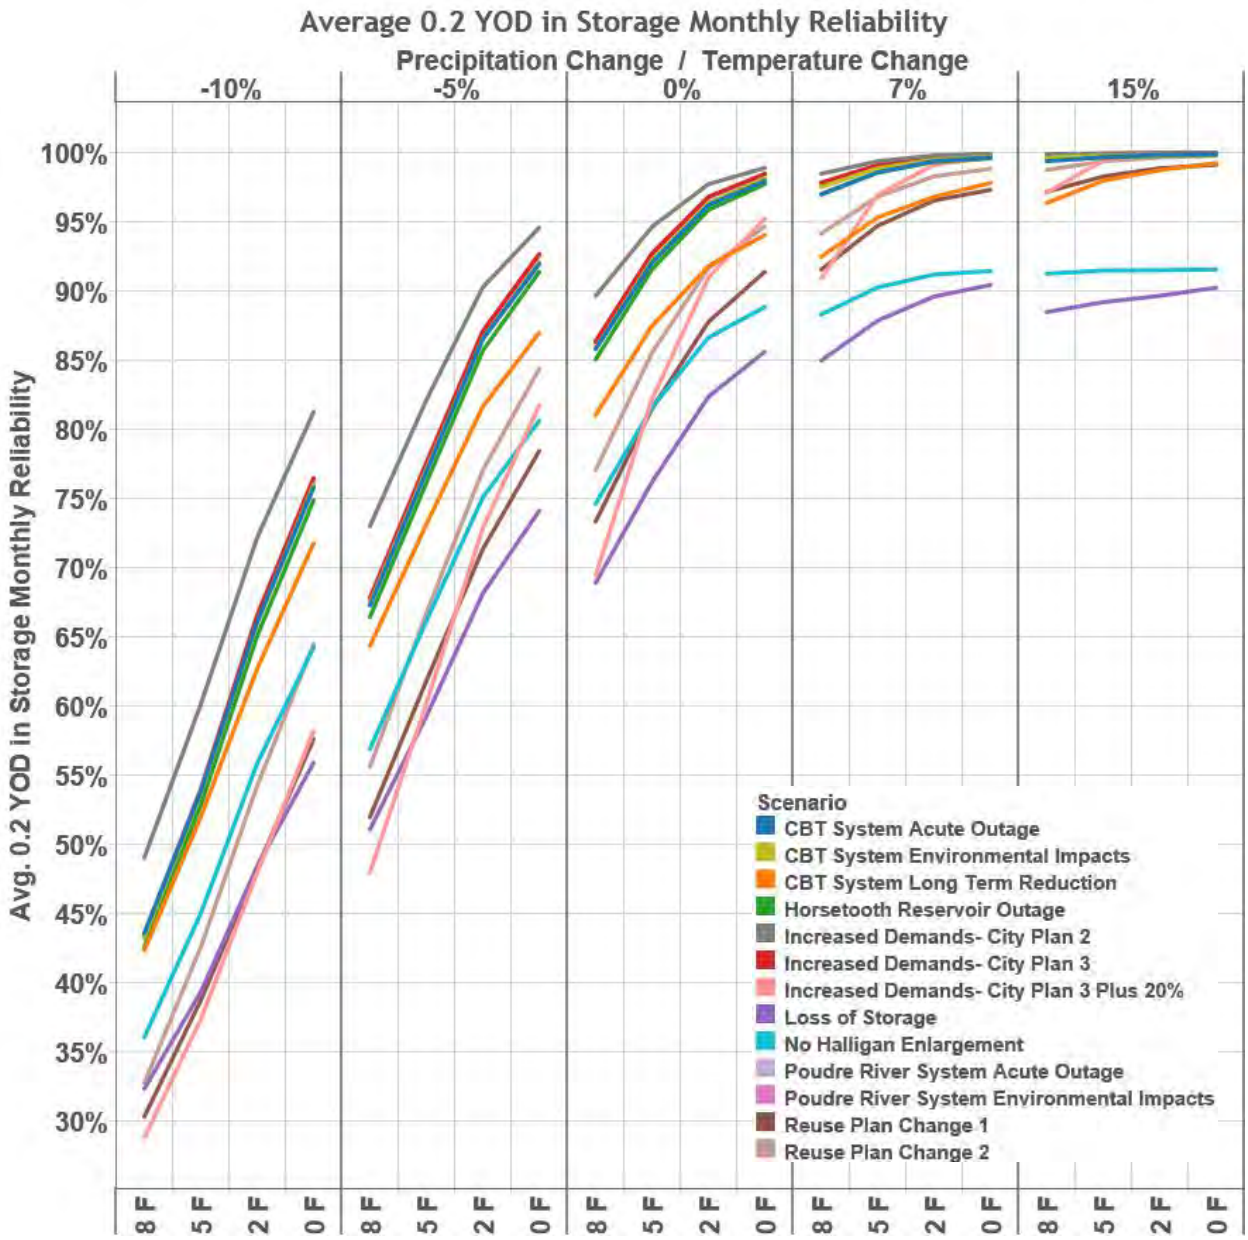

Figure 7-21 Storage Reserve Metric for All Risk Scenarios

Notes:

a) Poorer performance indicated by lower reliability towards bottom of graph.
b) YOD = years of annual demand.
c) Water supply planning policy goal is 100%

The Loss of Storage and the No Halligan scenarios have very poor performance for the storage reserve factor reliability metric (**Figure 7-22**). The Loss of Storage scenario assumes No Halligan Enlargement of 8,125 AF and no use of C-BT Carryover storage. FCU does not have many reservoirs and without these storage accounts, overall storage reserves are reduced and the ability to keep 20% of the annual demand in storage becomes very difficult. Even in wet future climate conditions, the performance of this metric is low. In these conditions, there is more supply than for the drier climates but because these two risk scenarios have less reservoir storage, it is still more difficult to maintain the 20% SRF goal than under the other risk scenarios with more reservoir storage. These results point out the importance of the proposed Halligan Water Supply Project.

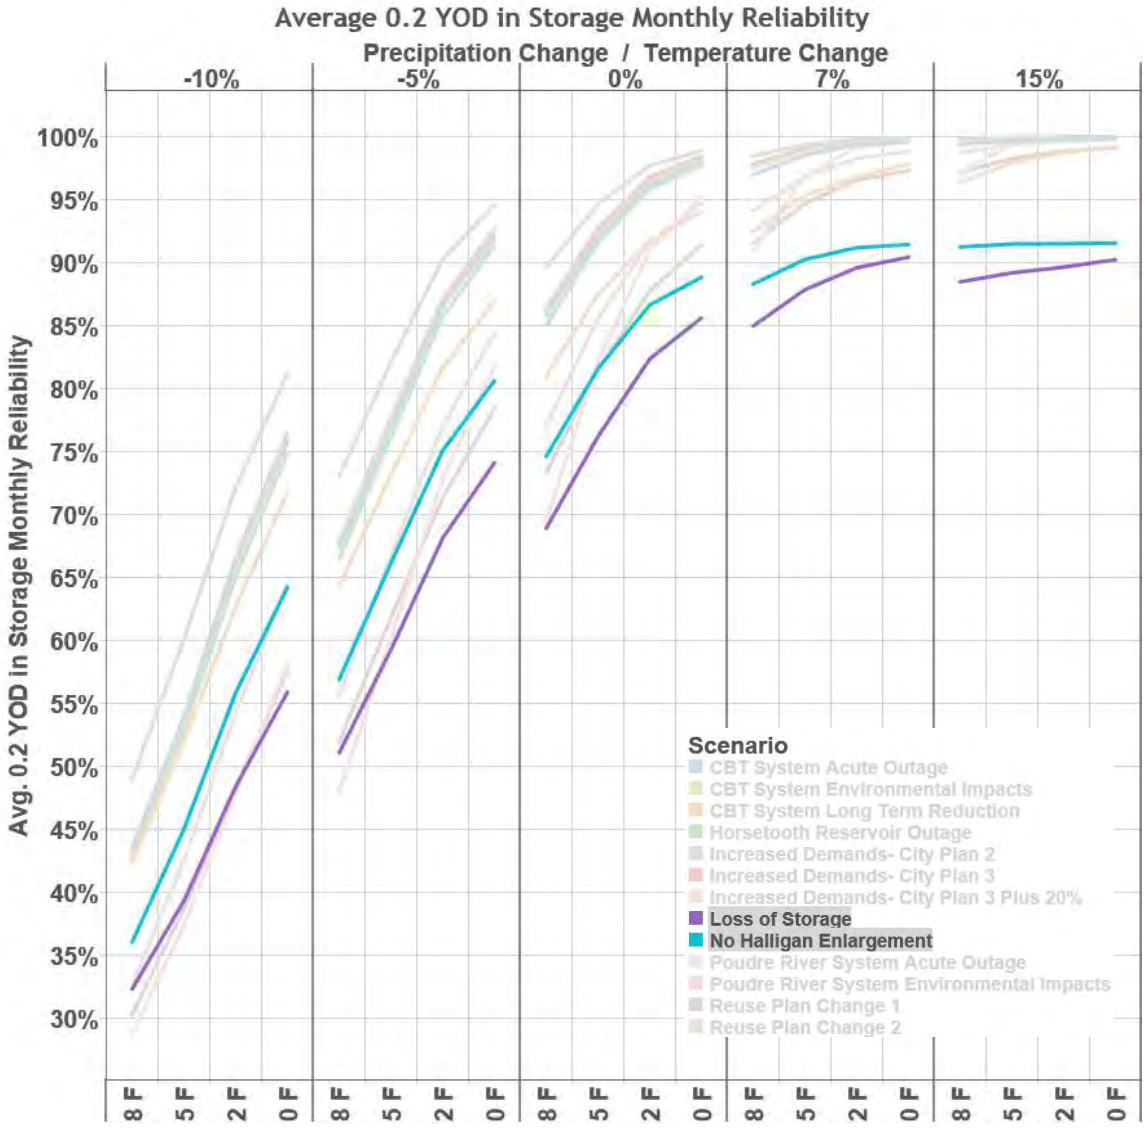

Figure 7-22 Storage Reserve Metric- Loss of Storage and No Halligan Enlargement Scenarios

Note: Poorer performance indicated by lower reliability towards bottom of graph

The Reuse Plan is a very important mechanism for increasing water supply in the FCU system. **Figure 7-23** shows impacts to the storage reserve metric without the Reuse Plan and with a 50% reduction in the ability to utilize the Reuse Plan. Lack of this supply requires heavier dependence on storage, thus depleting it beyond the 20% SRF threshold.

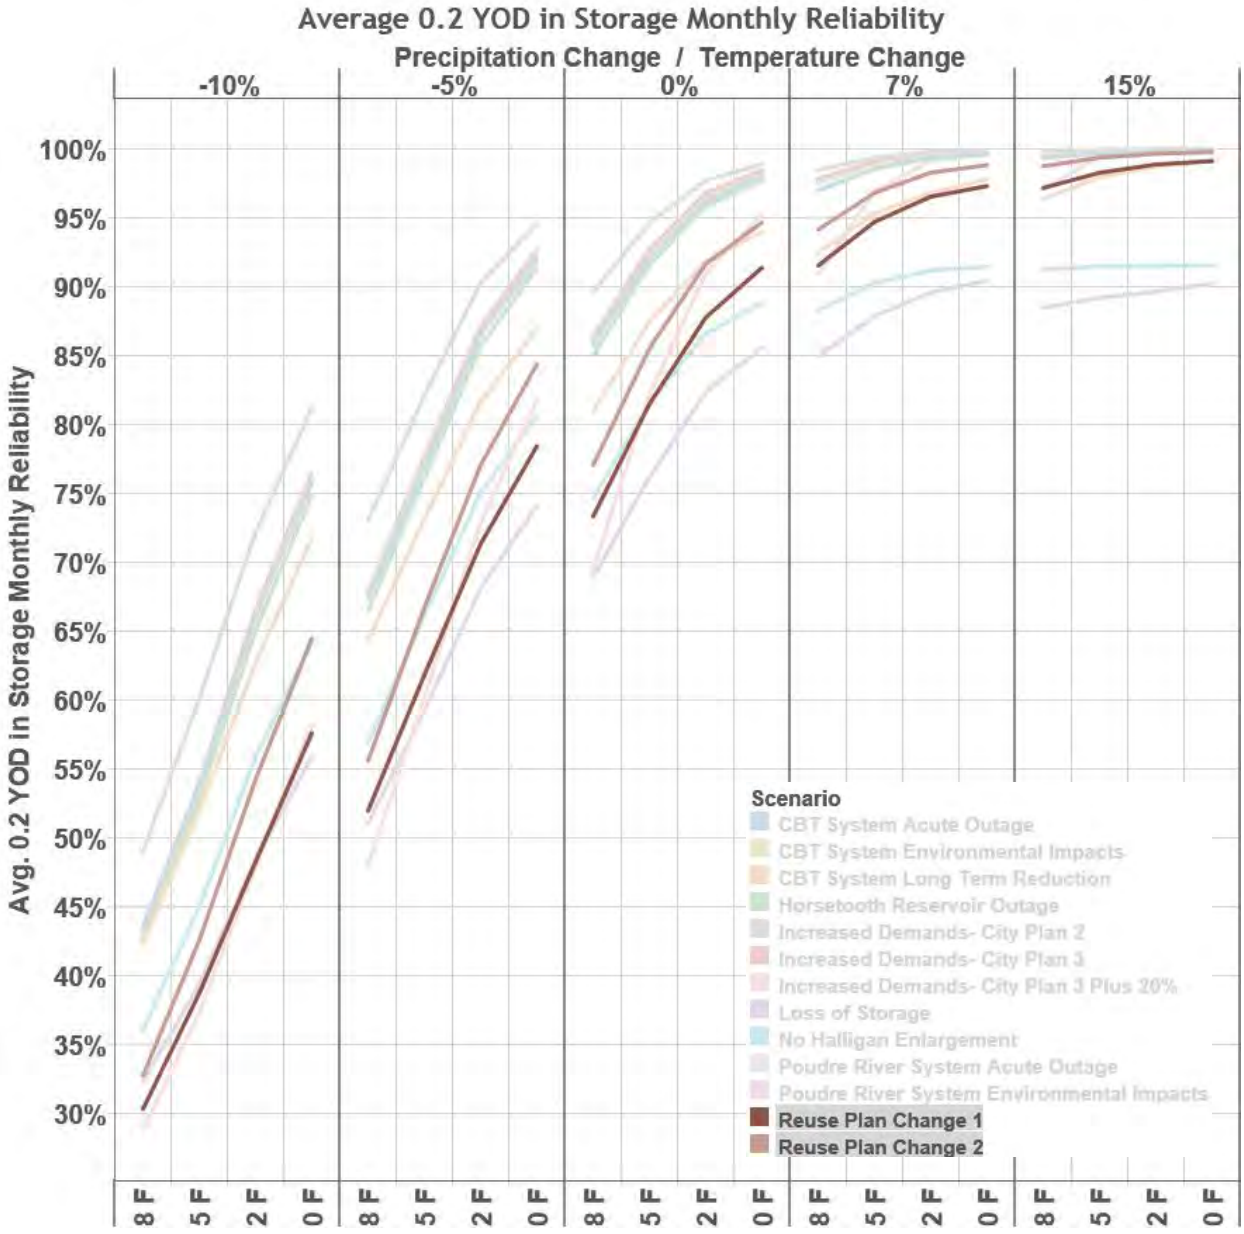

Figure 7-23 Storage Reserve Metric- Reuse Plan Change Scenarios

Note: Poorer performance indicated by lower reliability towards bottom of graph

A long-term reduction in C-BT supply simulated by a 25% quota for 10 consecutive years affects the storage reserve factor metric similarly to the Reuse Plan Change scenarios. C-BT water is an important supply for FCU and is also a critical component of the Reuse Plan. **Figure 7-24** shows that when this supply is significantly curtailed for a decade, the ability to meet the 20% SRF is diminished. Even scenarios with 15% increases in precipitation and no increase in temperature have a reliability of 99.3% for the 20% SRF metric and are thus, unable to meet the 100% reliability goal in the water supply planning policy.

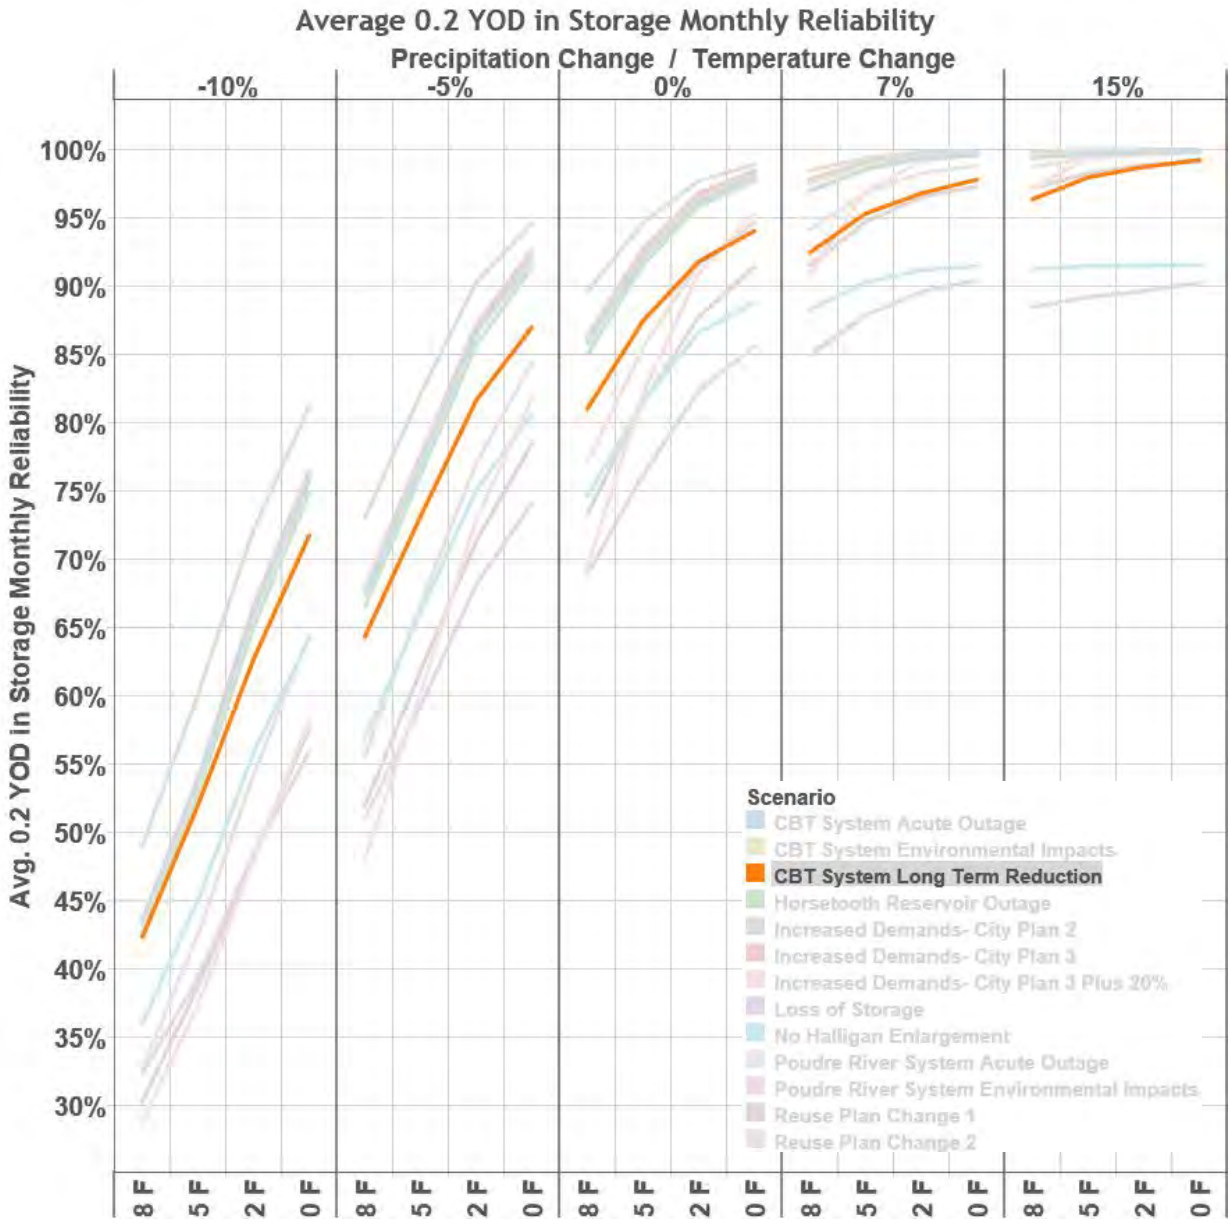

Figure 7-24 Storage Reserve Metric – C-BT Long Term Reduction Scenario
Note: Poorer performance indicated by lower reliability towards bottom of graph

7.5.3 Comparison of Scenarios Based on the Years in Restrictions Metric

A metric was calculated to determine how often water use restrictions would have been implemented during a model run based on the Fort Collins water shortage policy, assuming no demand management or emergency supply strategies were implemented. Water use restrictions could be triggered by impending shortages in meeting demand or total reservoir storage falling below the 20% SRF target. Because the current water supply planning policy sets a goal of meeting all demands during the 1-in-50-year drought and maintaining the 20% SRF without implementing water use restrictions, this “years in restrictions” metric provides a relative comparison of the threat of each risk scenario to cause violations of the policy.

WSVS simulations do not include demand management measures or changes to normal water resources system operations like FCU has implemented in the past and could implement in the future in response to droughts or other emergencies. Thus, the results should not be interpreted as an estimate of the frequency of declaring water use restrictions based on current FCU policy, but more as a proxy for the relative frequency with which FCU would have to implement responses based on its water shortage policy. Response of the FCU water resources system to water use restrictions is complex and implementing restrictions during one drought year may have continuing benefits by conserving supplies, thereby reducing or eliminating shortages in future dry years. It is noted that the limited storage in the FCU water supply system, relative to the annual demand, constrains the potential benefits of demand management in one year, on system performance in subsequent years. Despite complex interaction of operations during drought or emergency periods, the results of the “years in restrictions” metric are useful for comparing the relative threat of triggering water shortage response policy actions among the different risk scenarios.

The figures below show the percentage of years in which the FCU water system would have been in any stage of water restrictions based on the current Fort Collins water shortage policy. **Figure 7-25** shows results for this metric for all scenarios. Lines near the top of the graph indicate more time spent in restrictions and therefore, worse system performance.

Virtually all risk scenarios would drive the need for demand management or water supply enhancement actions to avoid violations of the water supply planning policy criteria. Future temperature and precipitation significantly affect the threat of being in conditions that would trigger water use restrictions to meet the other policy criteria.

The following paragraphs discuss results for categories of similar risk scenarios.

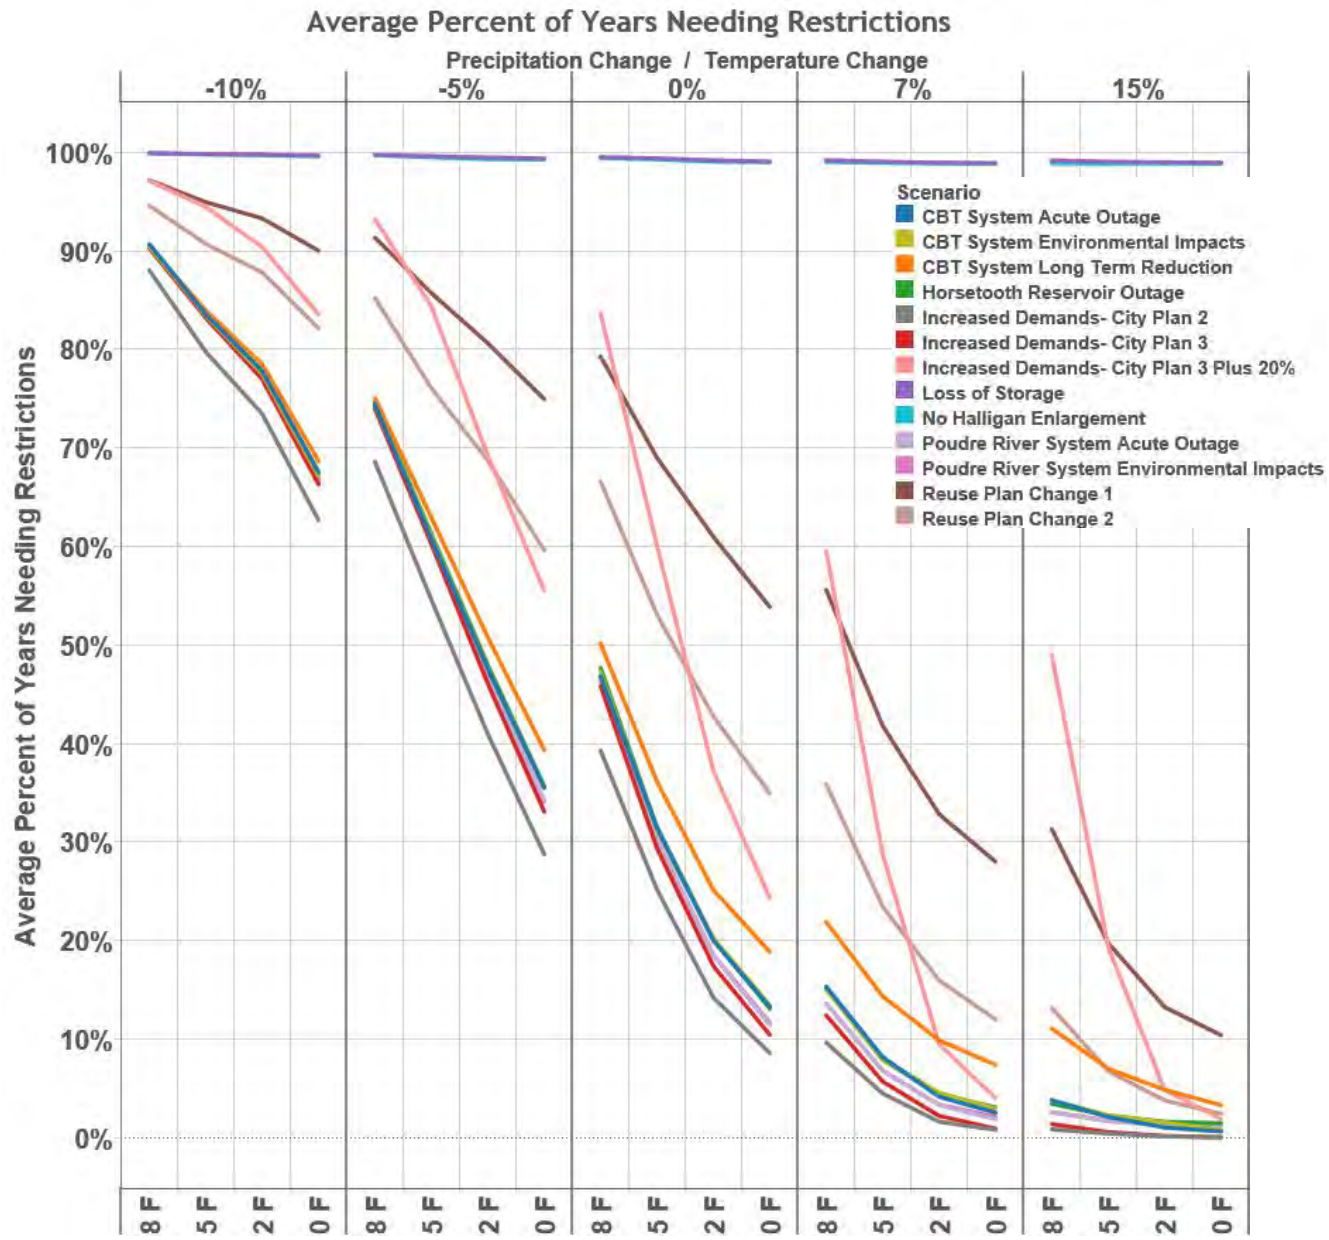

Figure 7-25 Years in Restrictions Metric for All Risk Scenarios

Notes:

a) Poorer performance indicated by greater frequency of being in restrictions towards top of graph

b) "Restrictions" is a surrogate for any demand management or emergency supply enhancement measures FCU would implement in response to potential violations of the water supply planning policy

Figure 7-26 shows that the No Halligan Enlargement and the Loss of Storage scenarios would require some level of restrictions throughout the simulations in at least 99% of years in the absence of implementing management measures. The proposed Halligan Reservoir Enlargement is a critical component of FCU's future water supply system and without it, current water supply planning policy criteria could not be met in most years.

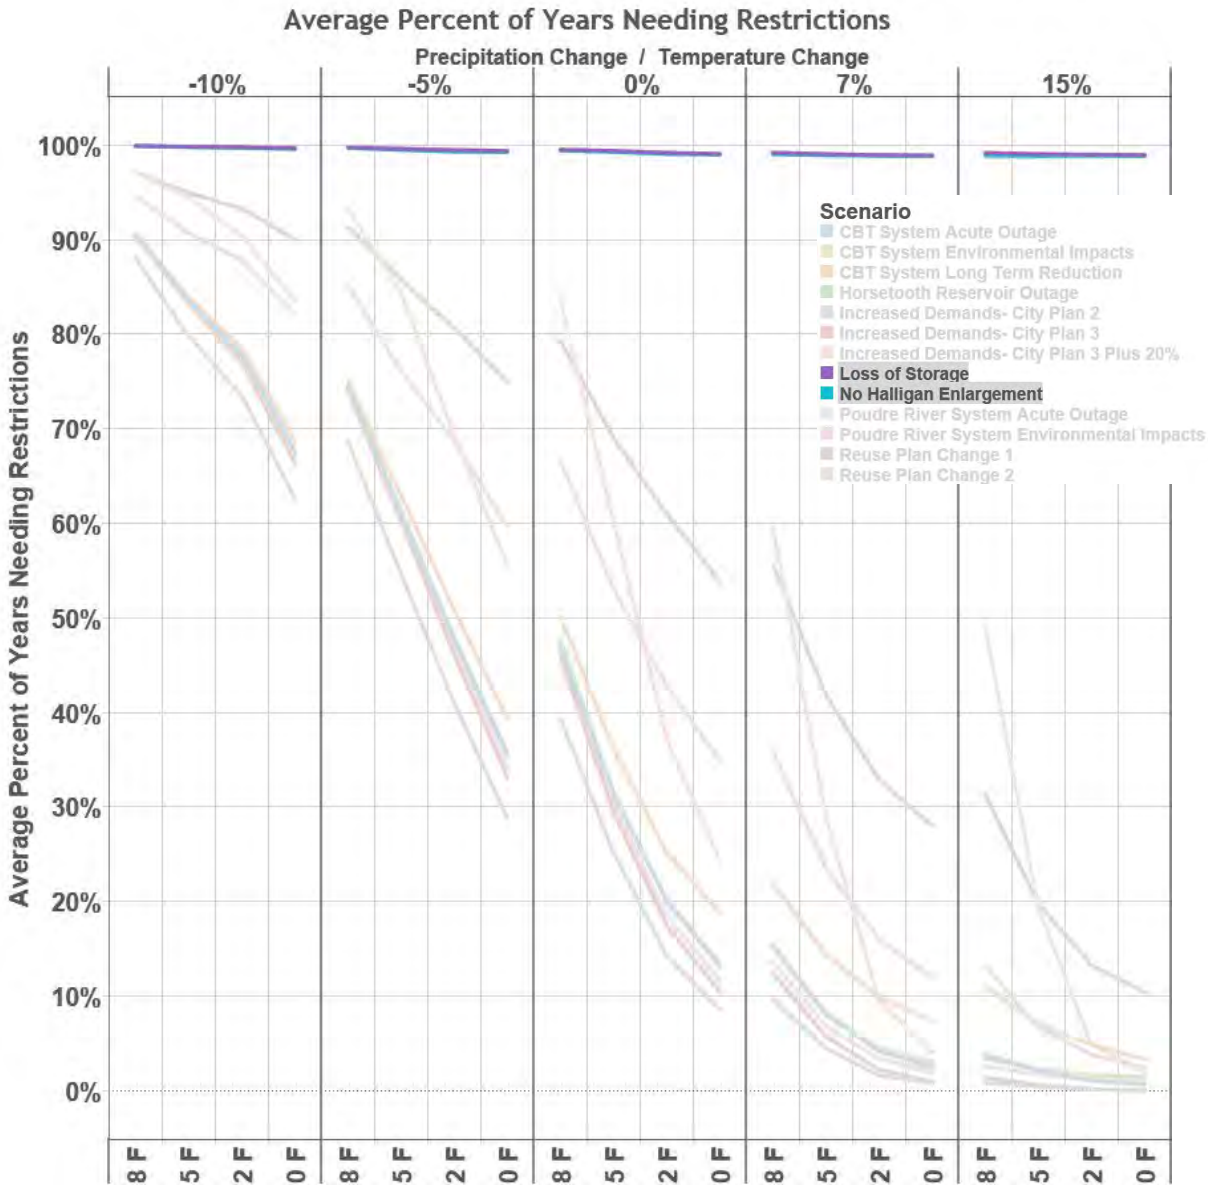

Figure 7-26 Years in Restrictions Metric- Loss of Storage and No Halligan Enlargement Scenarios

Notes:

a) Poorer performance indicated by greater restriction needs towards top of graph

b) "Restrictions" is a surrogate for any demand management or emergency supply enhancement measures FCU would implement in response to potential violations of the water supply planning policy

Figure 7-27 shows that any change to the reuse plan would increase the average percentage of years the system would be in restrictions without implementation of management measures. Either a 50% or a 100% reduction in the reuse plan would impact the system significantly, requiring the need for frequent restrictions or other demand management or supply enhancement measures.

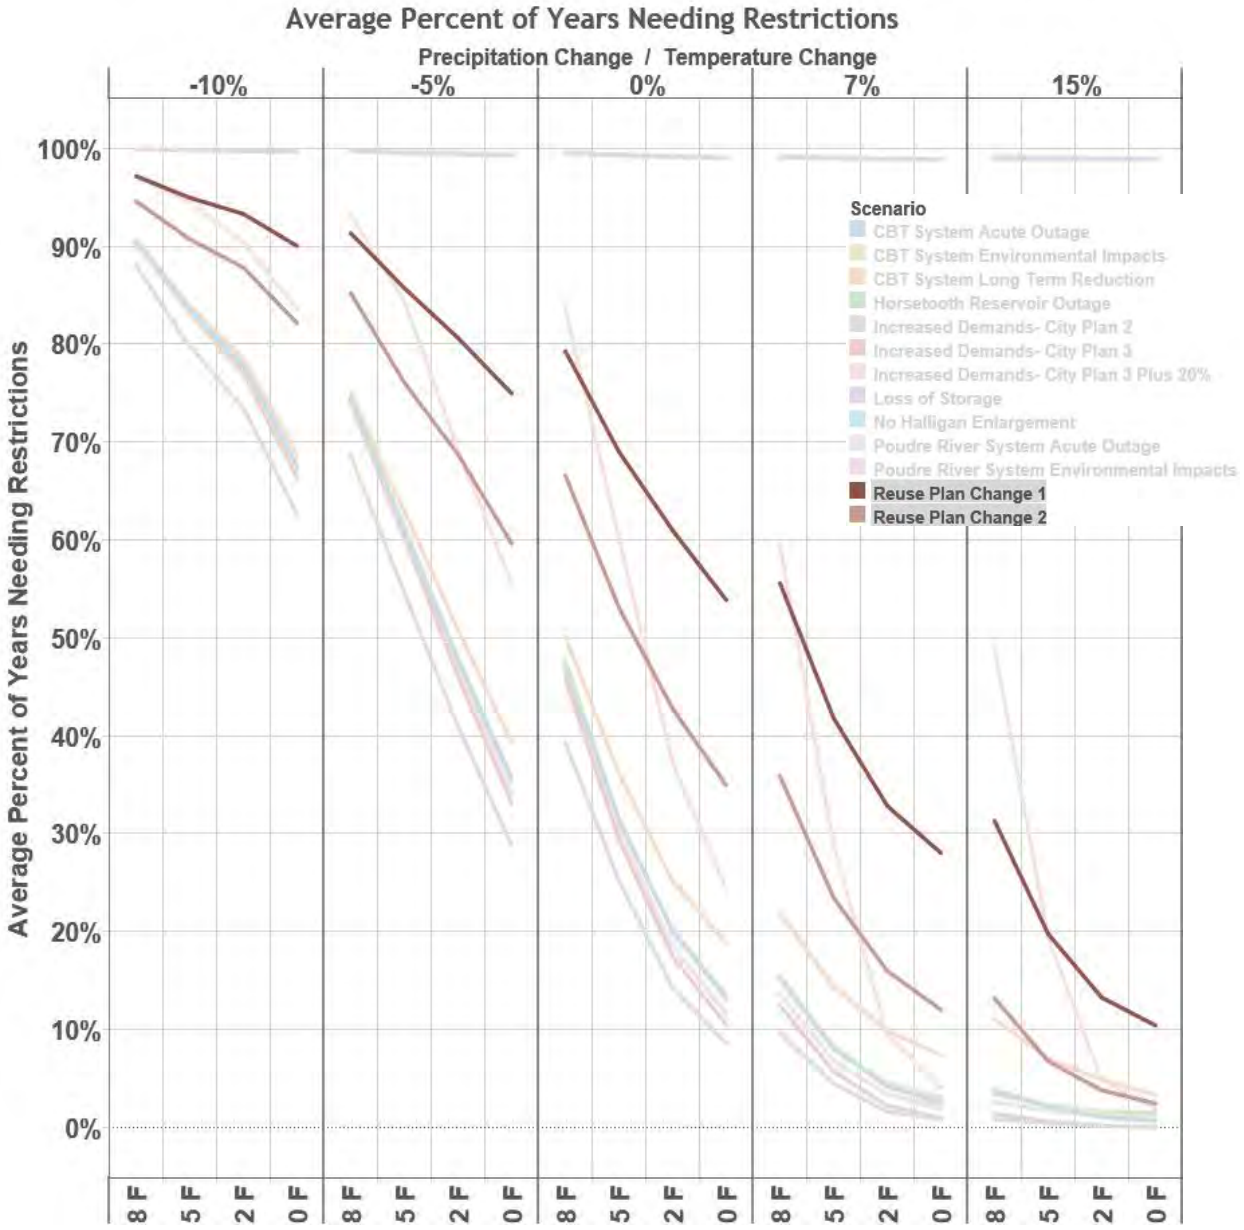

Figure 7-27 Years in Restrictions Metric - Reuse Plan Change Scenarios

Notes:

a) Poorer performance indicated by greater restriction needs towards top of graph
b) "Restrictions" is a surrogate for any demand management or emergency supply enhancement measures FCU would implement in response to potential violations of the water supply planning policy

7.5.4 Comparison of Scenarios Based on Indoor Demand Reliability Metric

The next set of figures, starting with **Figure 7-28,** show the reliability of meeting indoor demands for each of the risk scenarios. For modeling purposes, indoor demand is defined as the sum of February demand for the CityDem and LCU nodes in the FCSys model. Meeting all indoor demands with 100% reliability is a critical performance objective for FCU. Any situation with less than 100% reliability represents a public health crisis and a serious risk. It is important to note that watering restrictions or other demand management strategies were not modeled as a part of this study. FCU would take proactive steps to implement restrictions or obtain emergency supplies if there was a threat of not meeting indoor demands for all its customers. So, in practice, the actual indoor demand reliability would be much higher for any of the risk scenarios than calculated for the WSVS simulations. Results in this section are merely an indication of the relative threat among the risk scenarios for indoor demand shortages without implementation of appropriate management strategies.

Figure 7-28 is a parallel line plot showing the average indoor demand reliability metric for all risk scenarios and all climate conditions. Similar to the other metrics, the indoor demand reliability metric is strongly influenced by climate conditions. All risk scenarios for current and drier climates present a significant threat to meeting indoor demands with 100% reliability.

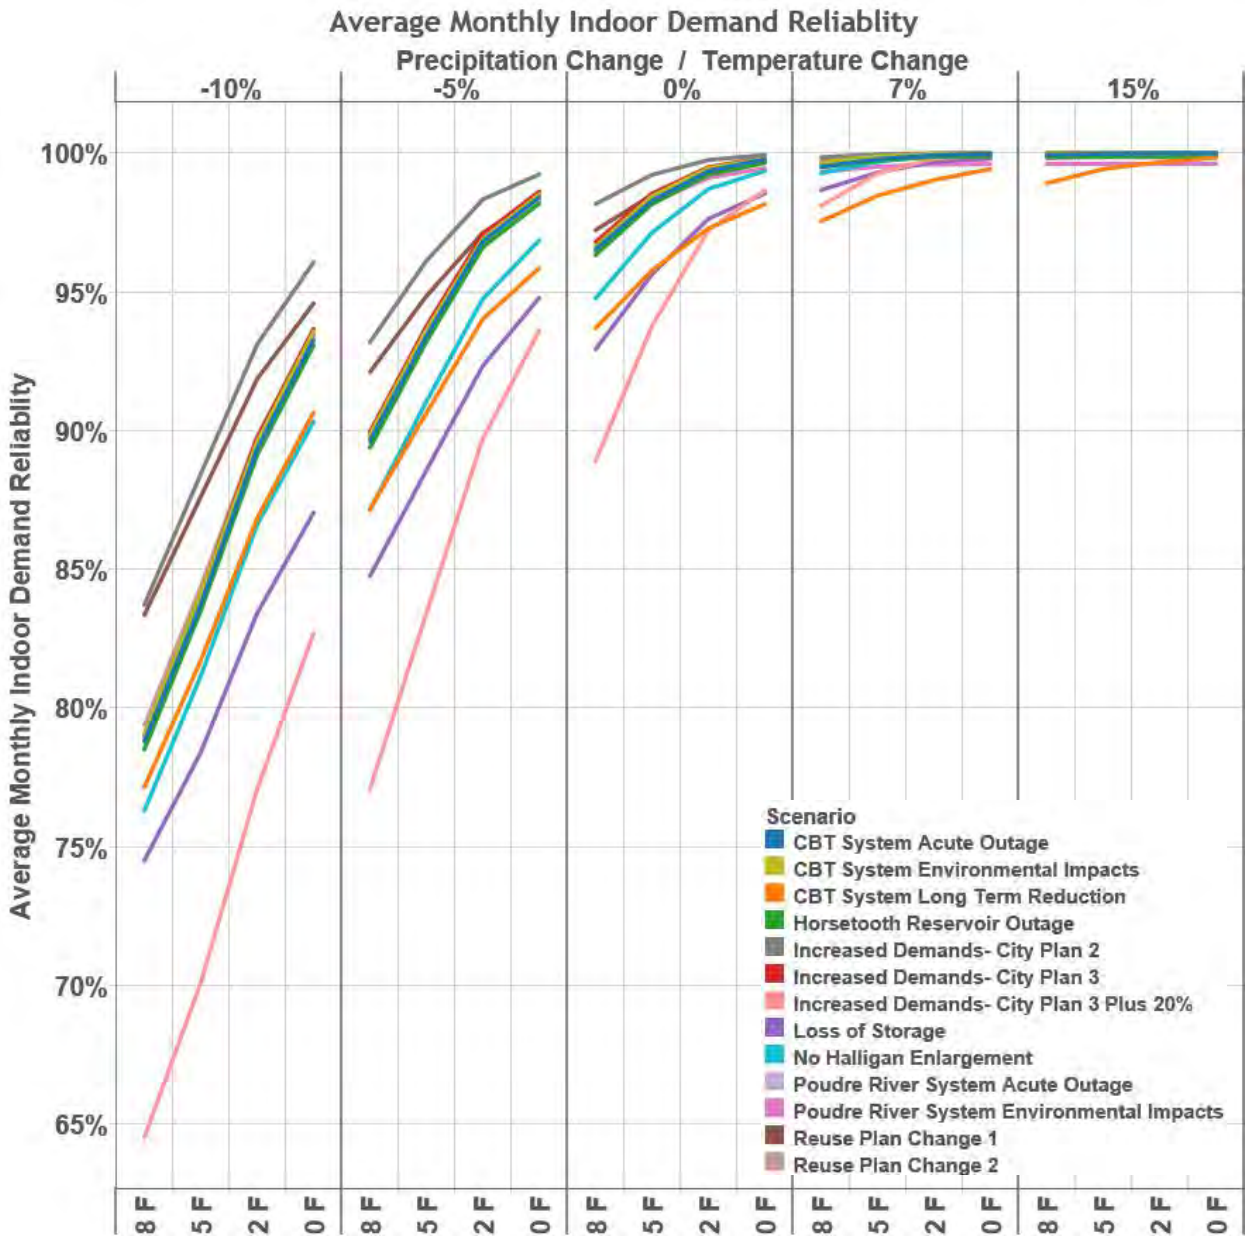

Figure 7-28 Indoor Demand Reliability Metric for All Risk Scenarios

Note: Poorer performance indicated by lower reliability towards bottom of graph. Water supply planning policy goal is 100%.

Figure 7-29 shows the performance of the Loss of Storage and the No Halligan Enlargement scenarios. Even under current climate conditions (T=0/P=0%), a reduction in storage due to loss of C-BT Carryover and/or the proposed Halligan Reservoir enlargement would create shortages in meeting indoor demands.

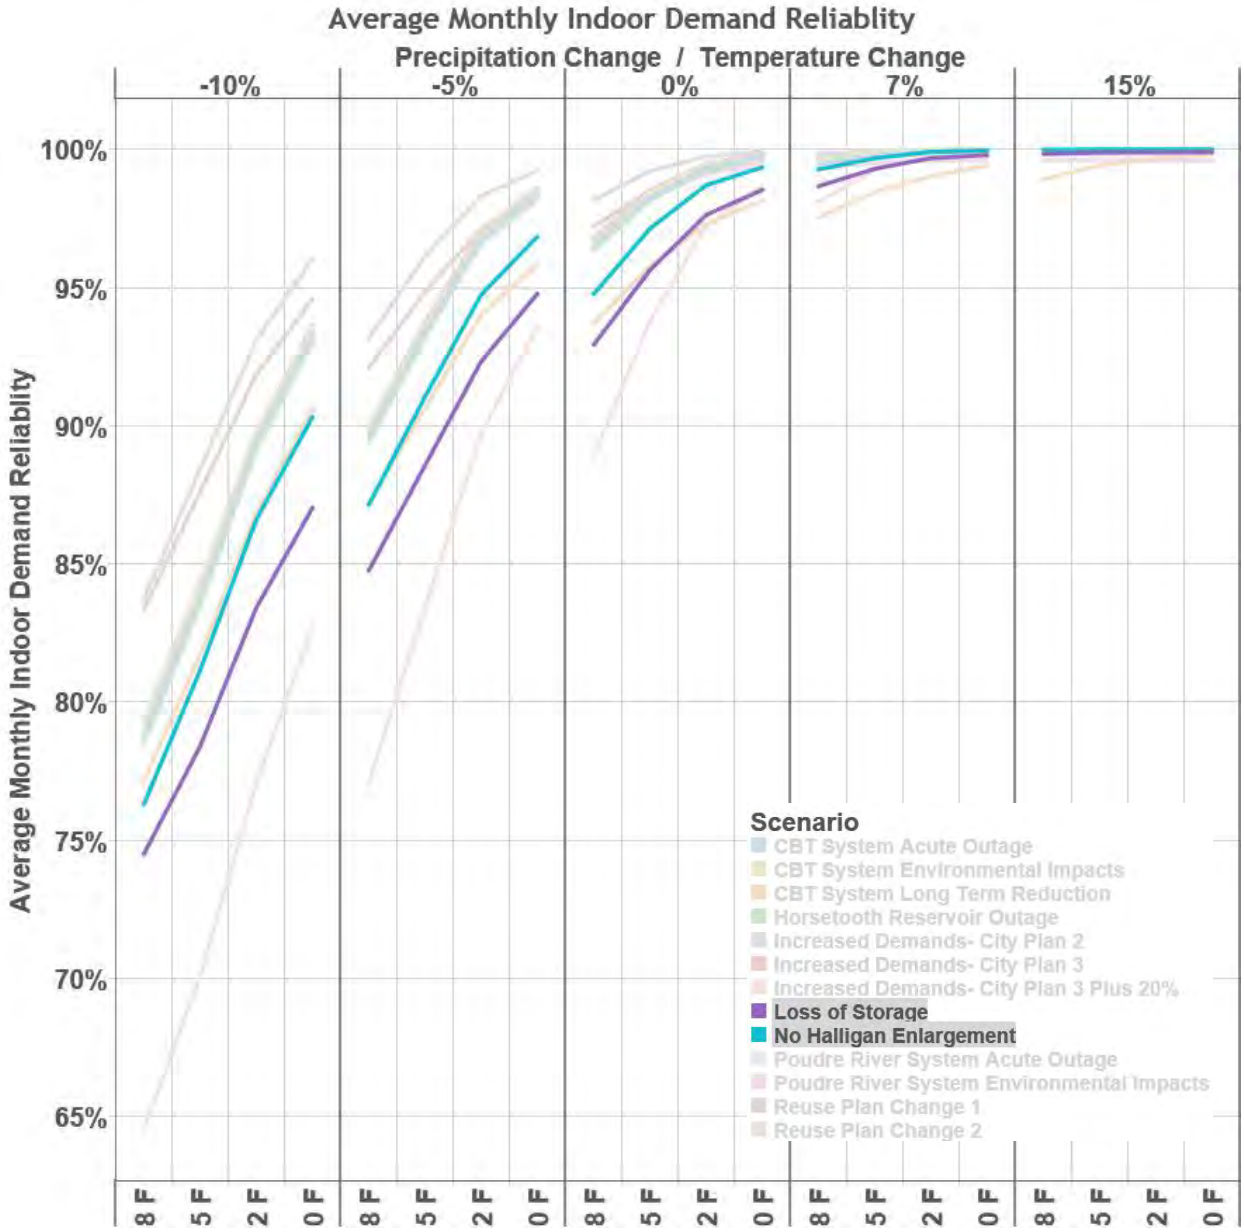

Figure 7-29 Indoor Demand Reliability Metric - Loss of Storage and No Halligan Enlargement Scenarios

Note: Poorer performance indicated by lower reliability towards bottom of graph

Figure 7-30 shows the C-BT Long Term Reduction Scenario represents a critical risk to the ability to reliably meet indoor demands. Even with a 7% increase in precipitation and no change in temperature, the current system is unable to meet indoor demands with 100% reliability. This risk is driven strongly by temperature increases. In the wettest future (+15% precipitation), this is the only risk with decreasing indoor demand reliability as temperature increases.

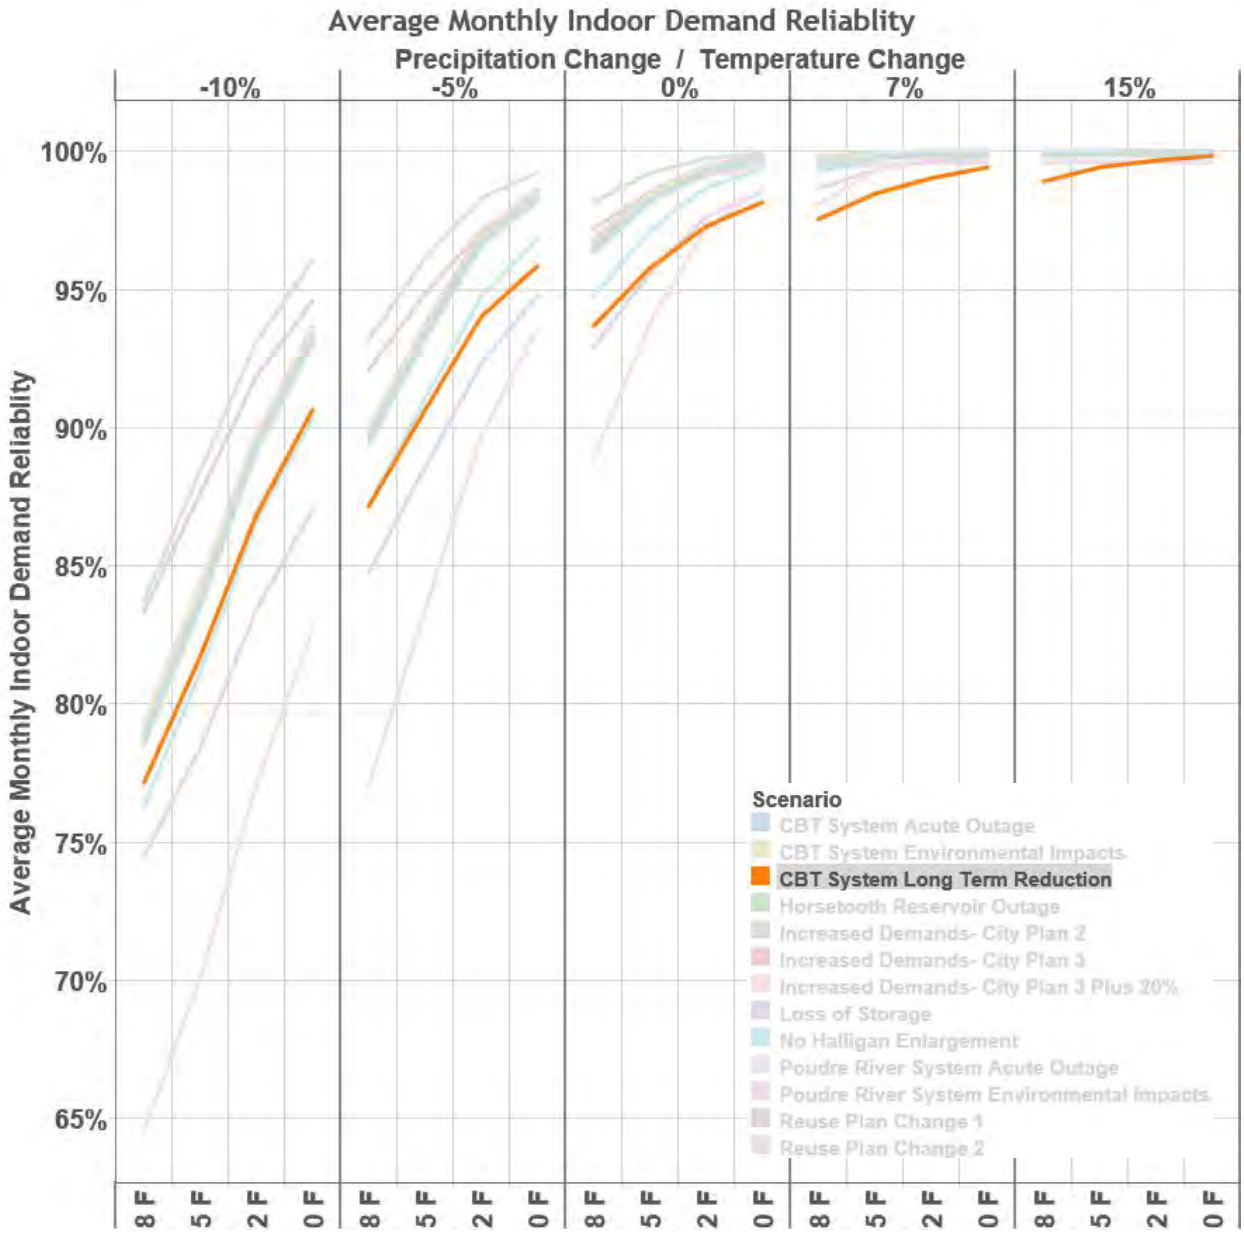

Figure 7-30 Indoor Demand Reliability Metric – C-BT Long Term Reduction Scenario
Note: Poorer performance indicated by lower reliability towards bottom of graph

7.5.5 Timing of Risk Scenario Impacts

Impacts of the risk scenarios are not evenly distributed throughout the year. Because demands vary seasonally and peak in the summer months, most risk scenarios affect the ability to meet the current water supply planning policy criteria in the fall and winter months when storage is depleted and streamflow yields have declined. To demonstrate this seasonal distribution of risk, histograms were prepared for the average number of months in which demand shortages occurred in simulations for the Loss of Storage Scenario (a long-term risk scenario) and the Poudre River System- Acute Outage Scenario (a short-term risk scenario) for City Plan 3 demand and selected climate conditions.

Figure 7-31 shows the average distribution of the occurrence of demand shortages for selected climates under the Poudre River System Acute Outage Scenario. The figure reflects the count of demand shortages only; SRF shortages are not reflected in the figure. More detailed descriptions of the risk scenarios can be found in Appendix F. The three climates selected are wetter with no temperature increase (T=0 and P=+7%), current climate conditions (T=0 and P=0) and the most severe hot and dry climate (T=8 and P=-10%). Under wetter conditions, when the system is not stressed by climate, most shortages occur in the summer months of July, August and September. Comparing the wetter climate to the current conditions climate, August and September still stand out with the most shortages, but more shortages appear in all months relatively uniformly. In the most severe climate, only months of peak streamflow yield experience few shortages. This shows that climate has the largest effect on shortages in the fall and winter months, while the short-term risk itself causes shortages in the summer months even under a wet climate.

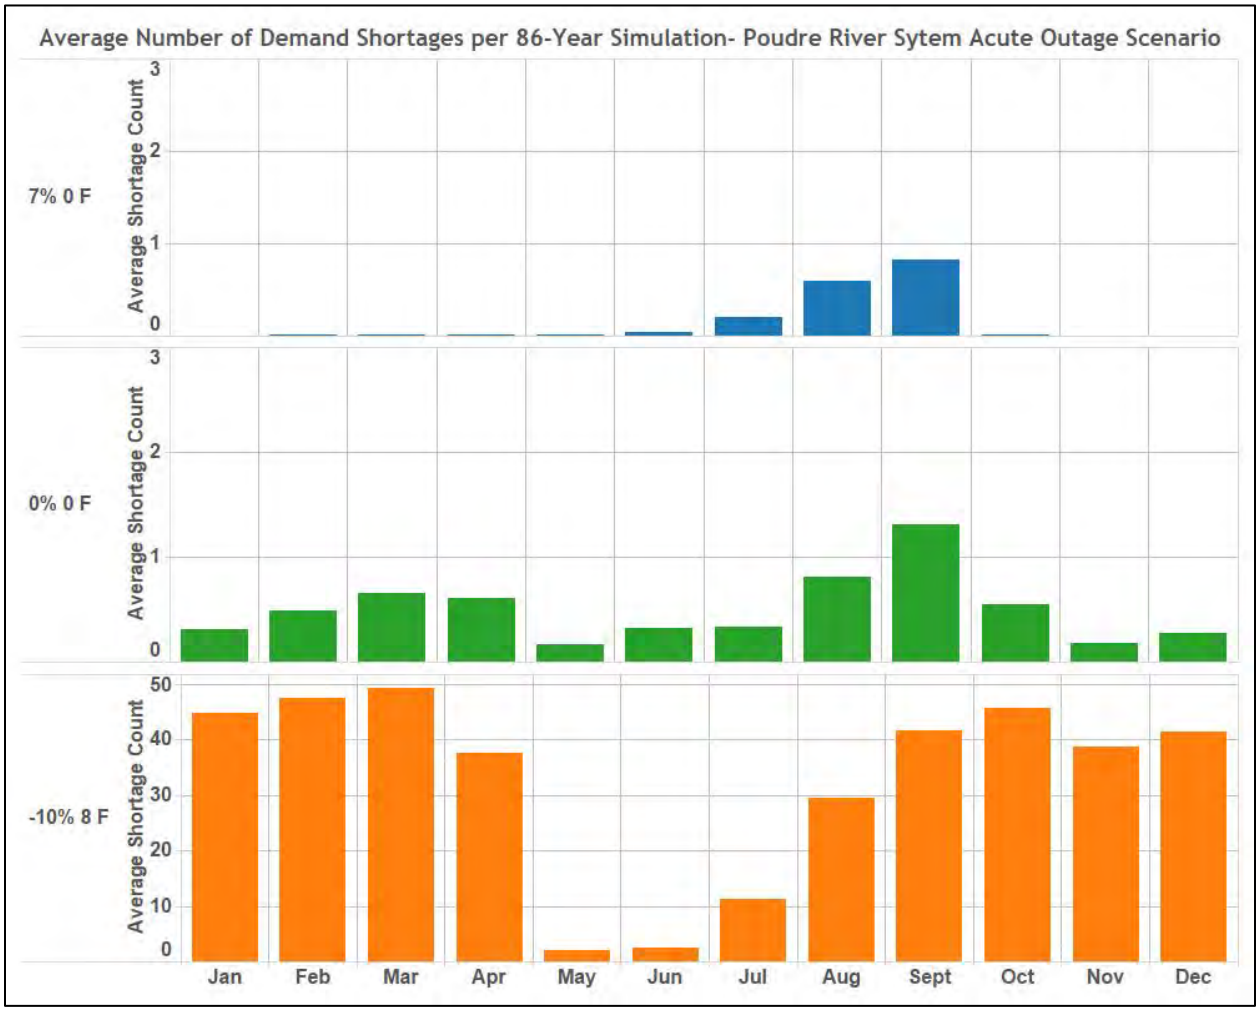

Figure 7-31 Average Monthly Distribution of Demand Shortages for Poudre River Acute Outage Scenario Under Selected Climates

Figure 7-32 shows the average distribution of the occurrence of demand shortages for selected climates under the Loss of Storage Scenario for the same three climates described above. The figure reflects the count of demand shortages only; SRF shortages are not reflected in the figure. The monthly distribution pattern is similar for the three climate conditions, with the direct runoff months of May and June being the only months when shortages rarely occur. More severe climates increase the number of shortages during the rest of the year but do not shift the seasonal occurrence of those shortages. This shows the extent of impact of not having sufficient storage to capture spring runoff for use until the next spring runoff occurs and show how that impact is more significant in warmer, drier climate conditions.

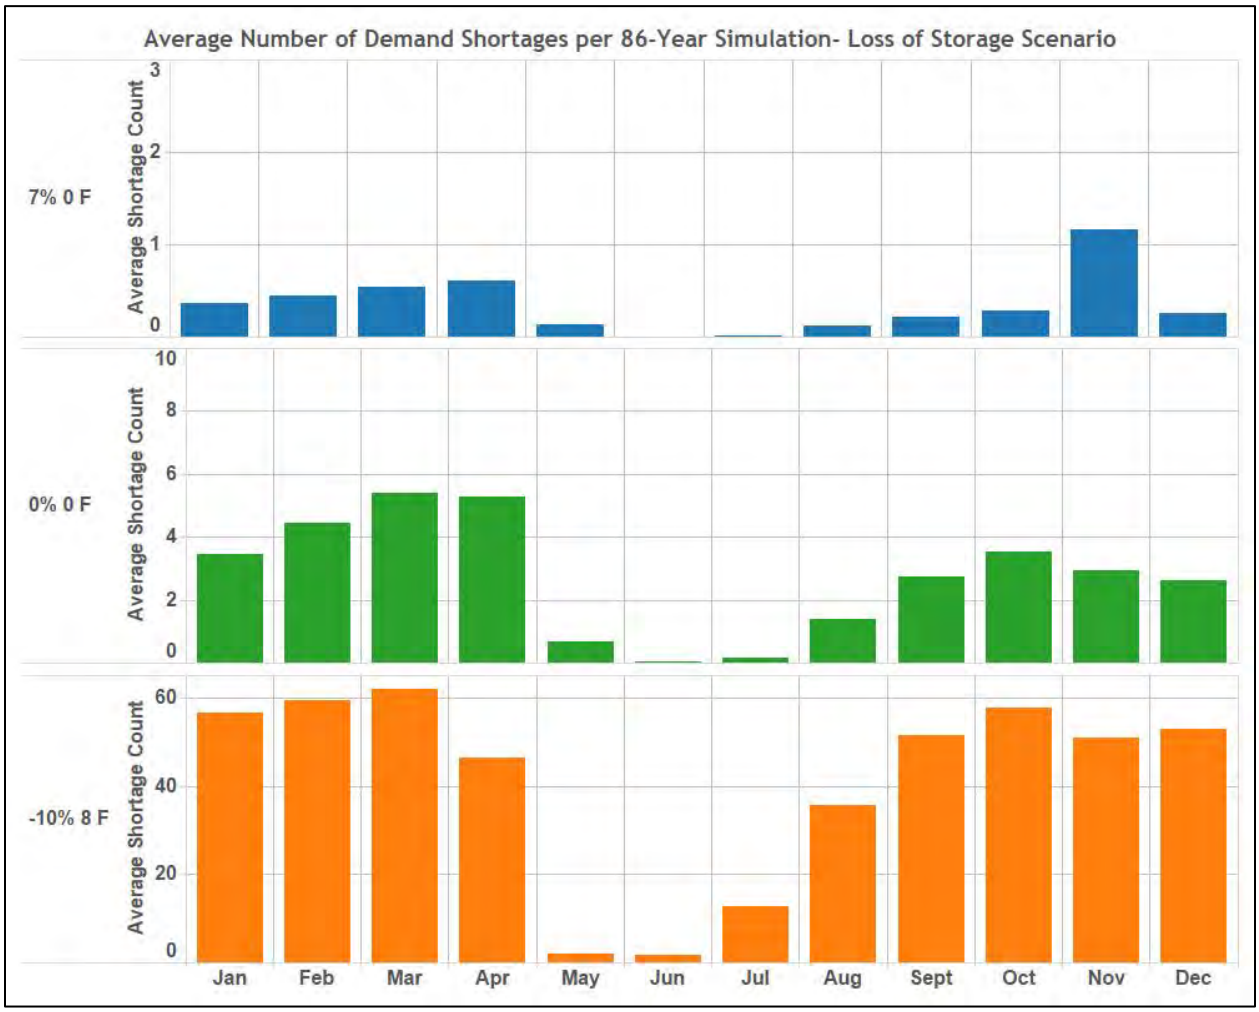

Figure 7-32 Average Monthly Distribution of Demand Shortages for Loss of Storage Scenario Under Selected Climates

7.5.6 Summary of Findings for Risk Scenarios

This section summarizes the primary findings from the analysis of the risk scenarios simulated for the WSVS.

- Climate is a critical driver for FCU system performance. Regardless of the scenario, future climate will have a dramatic effect on FCU system performance and the ability of FCU to meet all criteria of its current water supply planning policy. A hotter, drier climate would severely stress the current FCU water resources system with or without the occurrence of other system risks. It would reduce supply, increase demand, shift runoff earlier making existing reservoir storage less effective and trigger other potential environmental effects. In general, climate has a more significant effect on system performance than increased demand over the range of climate conditions and future demands simulated in the WSVS. The more severe climates may also have a more significant impact than any of the assumed risk scenarios at current climate conditions. As shown in **Figure 7-16**, the number of years with annual demand shortages ranges from 1 to 10 across all the risk scenarios at the current climate (T=0, P=0%); in contrast, the number of years with annual demand shortages ranges from 54 to 75 for the hottest, driest climate condition (T=8, P=-10%) and from 0 to 2 for the coolest, wettest climate condition (T=0, P=+15%). Thus, future climate conditions may be more impactful to FCU's ability to meet its water supply planning policy criteria than the occurrence of any particular infrastructure outage or environmental condition simulated in the WSVS risk scenarios.

- Water demands higher than those forecast in the City Plan 3 scenario represent a significant vulnerability to the current FCU system. This points out the importance of FCU maintaining its water conservation program and working with City Planning Department to closely monitor population and development density trends to see how they are tracking with City Plan assumptions. An increase in 2070 demands by 20% significantly increases shortages and incidence of failures to meet the water supply policy requiring 20% of average annual demand in storage at all times.

- The top risk scenarios representing vulnerabilities to the FCU system are:

    - **Elimination of the Reuse Plan**. Risks affecting viability of the reuse plan would reduce FCU's ability to make maximum use of its reusable water supplies, putting additional stress on local Poudre River water supplies and water from storage such that the system would be more susceptible to impacts of droughts and other reductions in supply.

    - **Loss of C-BT carryover storage and proposed Halligan Reservoir enlargement.** FCU has limited reservoir storage, so loss of these storage options would make it impossible for FCU to meet its current water supply planning policy criteria under most future climate and demand conditions. Storage is particularly important in meeting demands late in the year after runoff has declined, so loss of storage would increase the threat of fall and winter shortages.

- **Long-term reductions in C-BT imports due to shortages in the Colorado River system**. C-BT imports from the Colorado River Basin are a critical source of supply for FCU. A substantial reduction in the C-BT quota for 10 years would pose a significant threat to FCU's ability to meet its current water supply planning policy criteria. This risk is the most impactful to meeting indoor demands at wetter climates, indicating that even under less severe climate futures FCU is still vulnerable to long-term reductions in C-BT imports.

Based on the ranking of risks and uncertainties in Section 5.2 and 5.3, many of the most critical long-term or chronic risks were found to be unlikely; however, their impact was estimated to be significant. The WSVS risk scenario simulations validated that assumption.

The risk scenario simulations demonstrated the fundamental difference between long-term or chronic risks and short-term or acute risks. All the most impactful risks based on the metrics used in the WSVS are long-term risks. This is biased by the metrics themselves which, with the exception of the annual demand shortage metric, are always calculated over the entire 86-year simulation period. Thus, long-term risks that adversely affect system performance over the entire simulation period or for many years within the simulation period affect metric values more than short-term risks that occur for only a few months or years. Short-term risks such as an outage of the Poudre River pipelines or C-BT facilities can have extreme impacts on system performance for a short period but are masked by climate shifts that cause significant long-term impacts to performance. The effects of long-term risks are not as easily masked by the shifts in climate, as their impacts are also significant over several years or the entire simulation.

Figure 7-33 highlights the average annual shortage volume metric and **Figure 7-34** highlights the storage reserve metric for the five short-term risks simulated for the WSVS. These figures show that most of the short-term risk scenarios have very similar performance when measured by the WSVS metrics. This is particularly true for the 20% SRF metric. The two short-term Poudre River risk scenarios show a more pronounced response to wetter climate conditions for the average annual shortage metric than the other short-term risk scenarios. The frequency of shortages due to climate influence is reduced for wetter climates, and when shortages do occur for these risk scenarios their magnitude is quite large, resulting in a high average shortage volume metric value. In this case, instances of failure to satisfy the current water supply planning policy criteria would be brief but impacts could be significant without application of appropriate mitigation strategies.

Additional investigation may be warranted to develop different metrics that are useful in comparing performance of short-term risks to each other. Strategies for addressing short-term risks in a future water resources plan may differ from strategies addressing long-term risks; e.g., they may include short-term emergency operations that would be effective over a period of weeks or months but not for multiple years. Referring to the ranking of risks and uncertainties in Section 5.2 and 5.3, many of these short-term risks received relatively high composite scores (likelihood multiplied by impact), meaning they are of high concern to FCU staff and should be further assessed.

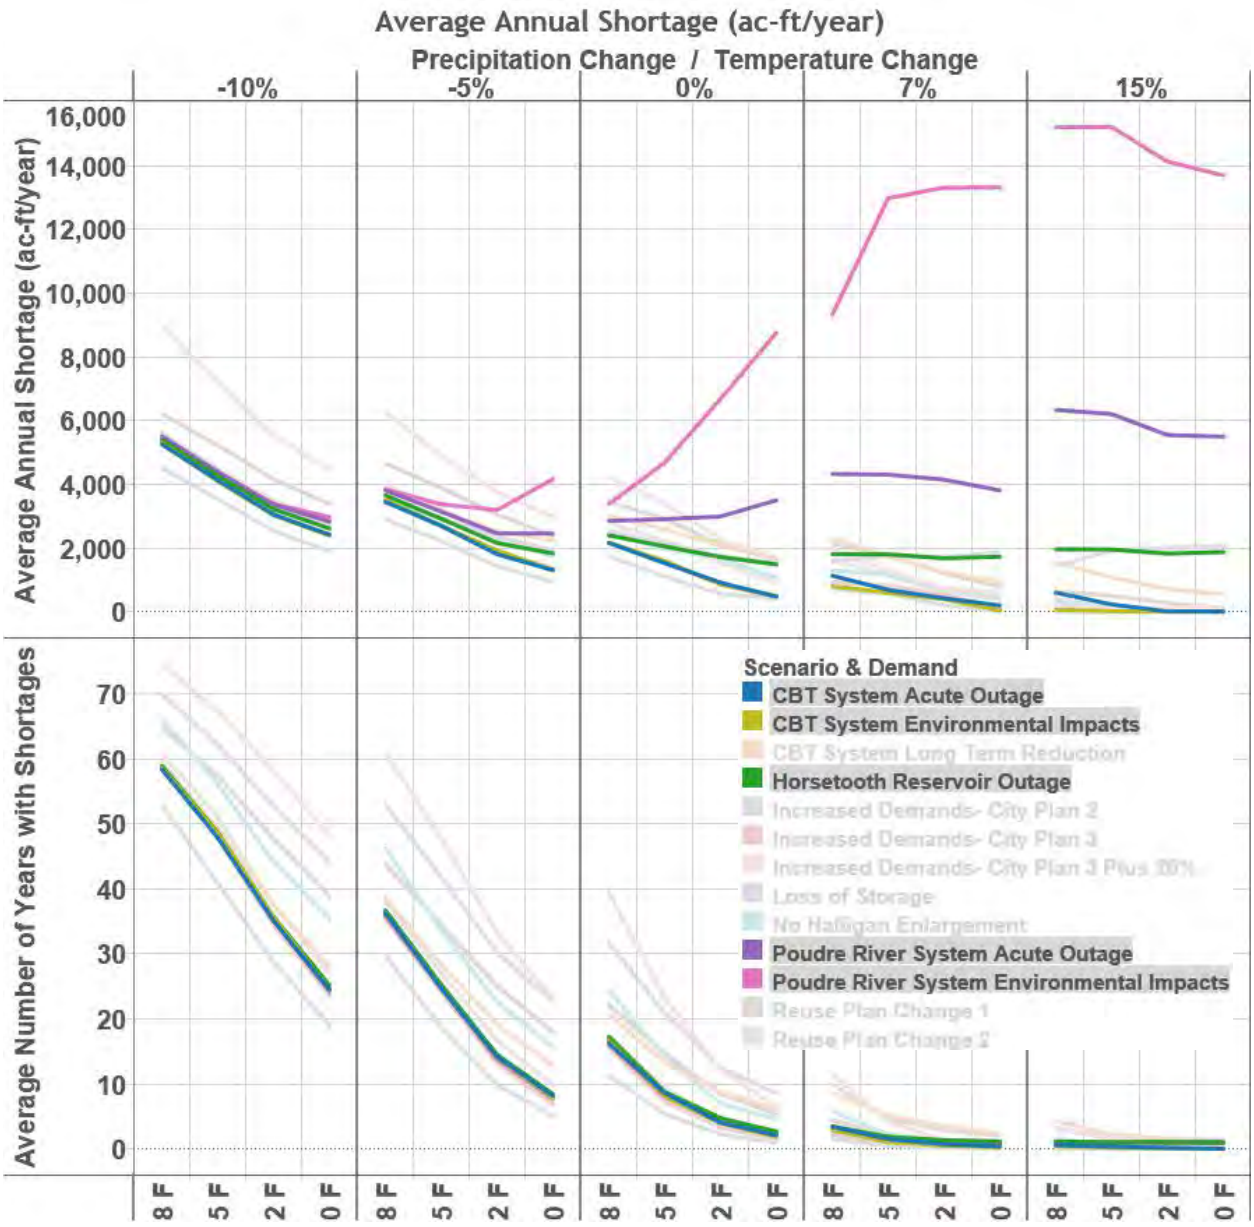

Figure 7-33 Average Annual Shortage Volume for Short Term Risks Compared to Long Term Risks

Note: Poorer performance indicated by greater shortage towards top of graph

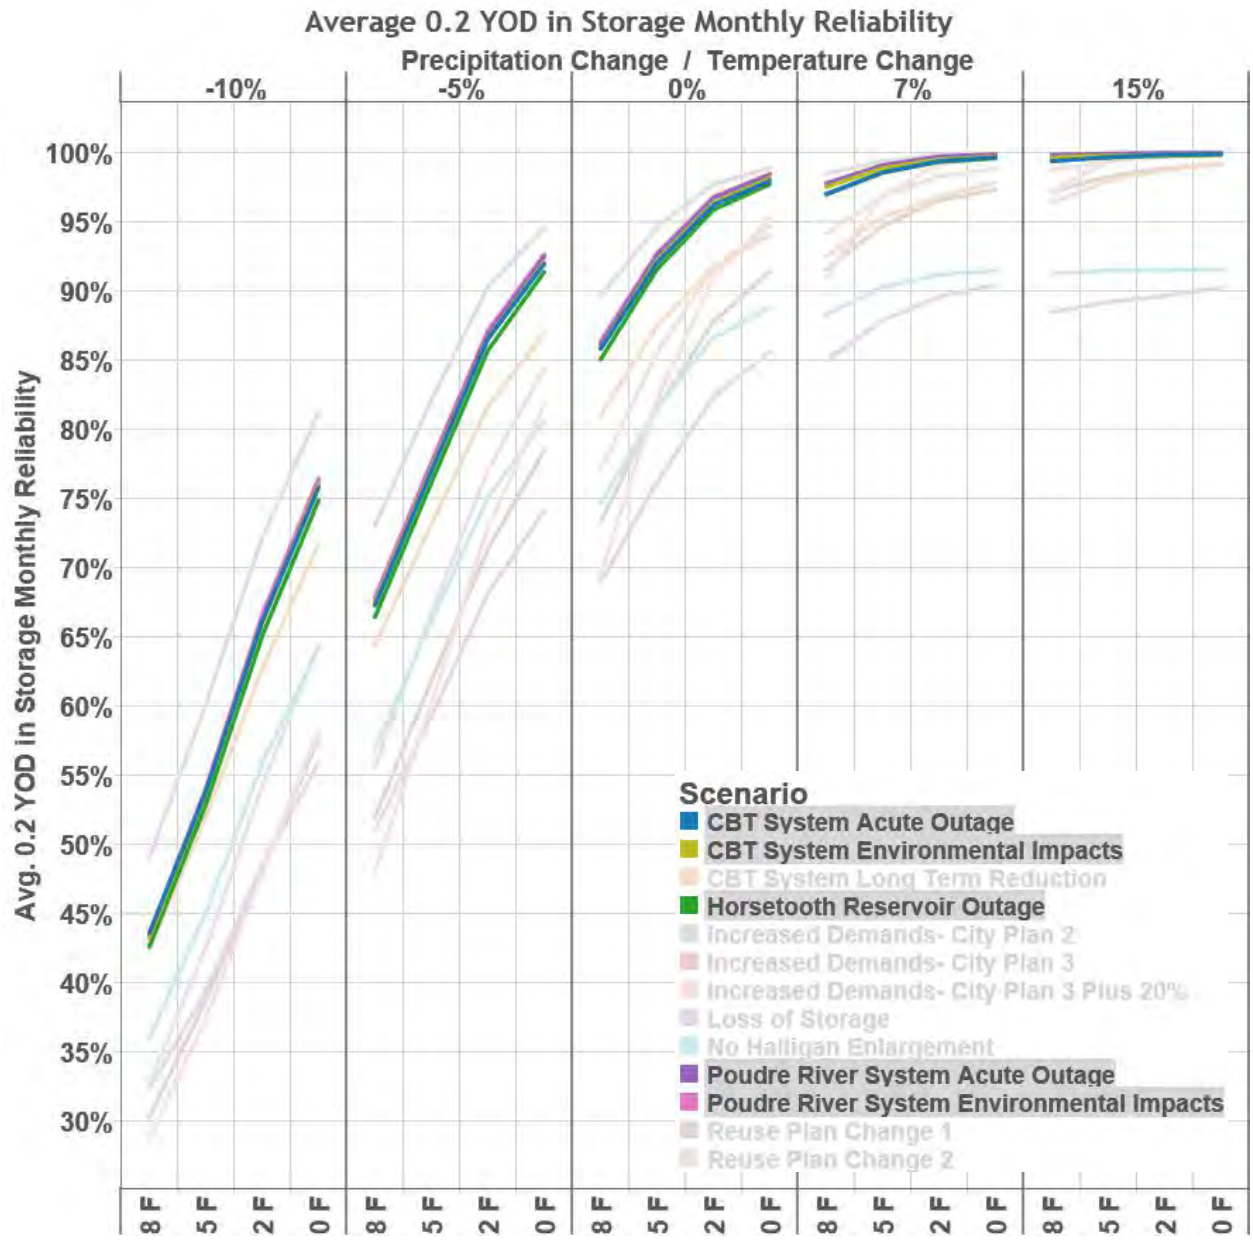

Figure 7-34 Reliability of Retaining 20% Storage Reserve for Short Term Risks Compared to Long Term Risks

Note: Poorer performance indicated by lower reliability towards bottom of graph

7.6 SUMMARY OF RISK SCENARIO RESULTS FOR SELECTED FUTURE CLIMATE CONDITION

FCU will use the results of the WSVS to update its Water Supply and Demand Management Policy. In the process of updating the policy, FCU may select a particular future climate condition or range of climate conditions to focus development of water supply alternatives. Mid-term planning could be based on a moderate climate future, such as T=5/P=0, while long-term planning may be based on a more severe climate future.

To show how the results of the WSVS could be used at that stage of water supply planning, results of the risk analysis are summarized below for the T=5/P=0 climate condition. These descriptions tie key metrics for this one possible climate condition to the current water supply planning policy.

- For the climate change risk alone (i.e., not combined with other risk scenarios), the chances of not meeting the 20% SRF would decrease from 84% of years to 67% of years when compared to current climate. Implementation of management measures such as water use restrictions would be required in about 33% of years compared to 16% of years for current climate conditions.

- For City Plan 2 and City Plan 3 demands in 2070, demand shortages would occur in about 8% of years; the 20% SRF would be met in 73% of years, and implementation of demand management or supply enhancement measures would be needed in about 27% of years. For City Plan 3 + 20% demands in 2070, shortages would occur in 27% of years; the 20% SRF target would be met in 50% of years; and implementation of demand management or supply enhancement measures would be needed in about 60% of years.

- Risk scenarios would reduce system performance such that shortages would occur in about 8% to 27% of years, depending on the risk scenario. The 20% SRF could be met between 1% and 76% of years over the range of risk scenarios. Most risk scenarios would force FCU to implement demand or supply management measures in the range of 25% to 36% of years. The Reuse Plan risk scenarios, scenarios involving loss of storage, and City Plan 3 + 20% demand scenarios cause higher risk of needing to implement management measures; water use restrictions or comparable options would be needed in 53% to 99% of years. Indoor demand shortages would occur in 6% to 21% of years across all risk scenarios, compared to 6% of years or less for the current climate across all risk scenarios.

Results indicate that even a moderate increase of 5 degrees in mean annual temperature with no change in mean annual precipitation has a significant adverse impact on the ability of FCU to meet customer demands as established in the water supply planning policy. At this climate, 2070 City Plan demands could be met in about 93% of years without implementing shortage management measures. Any of the system risks would require shortage management actions in anywhere from 29% of years to 99% of years based on the current water supply planning policy. Implementing water restrictions or other near-term strategies would probably not be enough to meet customers objectives under the current policy; new water supply projects would be needed to enhance supply.

8.0 CONCLUSIONS

The future is full of uncertainties. Fort Collins Utilities must make water supply planning decisions in the face of uncertain future water demand that is driven by complex demographic, economic and customer behavior factors; uncertain future hydrologic supply influenced by a climate that could be warmer and drier or warmer and wetter; and external risks to water supplies due to environmental influences and to infrastructure critical to the FCU water system. The WSVS provides FCU with an improved understanding of the most important risks and uncertainties to plan for in the future.

FCU's water system and water rights portfolio are well adapted to current climate conditions. With no change in average annual temperature or precipitation, the system performs well for the four metrics analyzed in this study (total demand shortage volume, reliability of maintaining a 20% storage reserve factor, reliability of not needing demand management measures like watering restrictions and reliability of meeting indoor demands).

However, once climate begins to shift towards hotter and drier conditions, the system performance begins to decline and the frequency with which FCU would have to implement demand management measures or access additional water supplies increases. Uncertain future hydrology is the most significant threat to FCU's future water supply, as global climate models have a wide range of predictions for the Poudre River and Upper Colorado River basins. Even the risk scenarios with the worst performance under current climate conditions perform better than a scenario with no system risks and an increase in temperature and decrease in precipitation. Thus, future climate conditions may be more impactful to FCU's ability to meet its water supply planning policy criteria than the occurrence of any particular infrastructure outage or environmental condition simulated in the WSVS risk scenarios.

Water demands higher than those forecast in the City Plan 3 scenario represent the next most significant vulnerability to the current FCU system. This points out the importance of FCU maintaining its water conservation program, and working with City Planning Department to closely monitor population and development density trends to see how they are tracking with City Plan assumptions. A 20% increase in the forecasted City Plan 3 demand due to increased population, large commercial users, expansion of the service territory, or other factors would stress supplies in all years and would be especially challenging in future hotter and drier climate conditions. The current FCU water supply would have to be enhanced or demand management measures would have to be implemented frequently to avoid shortages and to meet the 20% SRF goal.

Other risks found to have the largest impact on the FCU system performance are:

- Loss of storage, including no Halligan Reservoir enlargement; the FCU system is storage-limited so loss of any existing or proposed storage capacity has significant adverse effects.
- Reuse Plan changes, including elimination or 50% reduction in the amount of water incorporated in the Plan; the Reuse Plan is an efficient supply strategy that stretches current supplies, and losing all or part of it has compounding effects on FCU water supply.

- A long-term reduction in C-BT quotas due to C-BT supply or delivery infrastructure issues. C-BT supply is a critical part of FCU's water supply portfolio and reduction in that source over several years significantly impacts FCU's ability to meet its water supply planning policies.

Over the four metrics presented in this study, the above risks and risk scenarios show the poorest performance for current climate conditions and their performance is significantly reduced for the warmer and drier climates. These four risk scenarios create the greatest threats to meeting the current FCU water supply planning policy including frequent failures to meet total customer water demands, frequent failures to maintain the 20% storage reserve factor, and frequent years in which the current FCU water shortage response policy would call for implementation of water use restrictions or other emergency measures.

For most risk scenarios, shortages for climate conditions that are wetter than the current climate would occur most often in late summer and early fall. For warmer and drier climate conditions, shortages would occur throughout the year except in the peak runoff months of May and June. This shows the challenge of maintaining a resilient water resources system in the face of a warmer and drier climate with the limited amount of storage in the FCU raw water system.

Without the proposed Halligan Reservoir enlargement of 8,125 AF, FCU system performance would be significantly impacted and current water supply planning policy criteria could not be met under most future climate and demand conditions.

FCU may choose a moderate future climate condition as the focus for updating its water supply plan. If a future climate is chosen with 5-degree F warmer temperature and the same average annual precipitation, the following challenges would have to be addressed in meeting the current water supply planning policy.

- For City Plan 2 and City Plan 3 demands in 2070, demands shortages would occur in about 8% of years; the 20% SRF would be met in 73% of years, and implementation of demand management or supply enhancement measures would be needed in about 27% of years. For City Plan 3 + 20% demands in 2070, shortages would occur in 27% of years; the 20% SRF target would be met in 50% of years; and implementation of demand management or supply enhancement measures would be needed in about 60% of years.

- Most risk scenarios would force FCU to implement demand or supply management measures in the range of 25% to 36% of years. The Reuse Plan risk scenarios, scenarios involving loss of storage, and City Plan 3 + 20% demand scenarios cause higher risk of potentially needing to implement management measures; water use restrictions or comparable options would be needed in 53% to 99% of years.

- Indoor demand shortages would occur in 6% to 21% of years across all risk scenarios, compared to 6% of years or less for the current climate.

One approach to interpreting the WSVS results is to identify the risk scenarios that generate the greatest potential for failure to satisfy each of the current water supply planning policy criteria in 2070.

- **Total demand** (level of service target reliability = 100%). For warmer/drier climates, the most impactful risk scenarios are the City Plan + 20% demand and elimination of the Reuse Plan. For wetter climates, the most impactful risk scenarios are those that have short-term limitations on deliveries of Poudre River supplies.

- **20% storage reserve factor** (level of service target reliability = 100%). For warmer/drier climates, the most impactful risk scenarios are the City Plan + 20% demand and elimination of the Reuse Plan. For wetter climates, the most impactful risk scenarios are those that reduce storage, either through loss of C-BT carryover storage, loss of the ability to enlarge Halligan Reservoir as planned, or both. The FCU system has relatively little storage now, so loss of any current or proposed reservoir storage capacity significantly impacts the ability to meet this planning criteria.

- **Water use restrictions** (level of service target reliability = 100%; no restrictions or other emergency measures for the 1-in-50 drought). Loss of storage and elimination of the Reuse Plan are the most impactful risk scenarios in terms of creating conditions in which water use restrictions or some form of demand management or supply enhancement response would be required to prevent water shortages based on current water supply planning criteria.

- **Indoor demand shortages** (level of service target reliability = 100%). The City Plan 3 + 20% and Loss of Storage risk scenarios pose the greatest risk of not satisfying all indoor demands in 2070. For the warmest/driest climate, indoor demand reliability would be about 70% for these two risk scenarios; for current climate the indoor demand reliability for these scenarios would be about 90%; for the wettest climate the indoor demand reliability for these scenarios would be about 99.5%.

The risk scenario simulations demonstrated the fundamental difference between long-term or chronic risks and short-term or acute risks. Critical risks identified in the WSVS are long-term risks, impacting the FCU system for at least 10 years. However, many of the short-term risk scenarios may have a short-term, severe impact that was not fully captured in the metrics used in this study. The metrics are always calculated over the entire 86-year simulation period. Thus, long-term risks that adversely affect system performance over the entire simulation period or for many years within the simulation period affect metric values more than short-term risks that occur for only a few months or years. Short-term risks such as outage of the Poudre River pipelines or C-BT facilities can have extreme impacts on system performance for a short period, but this will not translate into a poor WSVS metric value when compared to the long-term risks in the study. Additional studies would be required to more closely analyze and rank the impacts of those short-term risks on the FCU water system.

FCU plans to use the results and conclusions of the WSVS as the foundation for updating its Water Supply and Demand Management Policy and its long-range water resources planning strategy. The following findings from the WSVS may be important as FCU contemplates the coming planning process.

- Climate change is the most important vulnerability faced by the FCU water supply system but it is the most difficult risk to track. Long-term trends are difficult to measure and are obscured by the

natural variability in wet and dry years. Participating in or keeping informed of state and federal climate change studies will help FCU understand the trajectory of climate change in the region.

- Water demands higher than those forecast in the City Plan 3 scenario represent a significant vulnerability to the current FCU system. This points out the importance of FCU maintaining its water conservation program and working with City Planning Department to closely monitor population and development density trends to see how they are tracking with City Plan assumptions. Increased water demand is the risk over which FCU, in collaboration with City Planning, has the most control.
- The WSVS analysis was performed without simulating the effects of demand management measures that FCU could adopt under the City's current Water Supply Shortage Response Plan. Investigating benefits of the current shortage response policy should be a key aspect of the water supply plan update.
- The WSVS highlights the importance of storage in the FCU system and the significant vulnerability posed by the inability to implement the proposed Halligan Reservoir enlargement or a similar storage project as a strategy to mitigate effects of climate change and other risks.
- The WSVS validates that FCU is highly reliant on the C-BT system and is particularly susceptible to extended periods of low quotas and loss of the carryover storage program. FCU should monitor conditions that could trigger either of those risks.
- Results of the WSVS are biased toward long-term risks, but a number of short-term risks were identified that could severely impact FCU operations for a few weeks or months. These conditions will require further study and may involve a different management strategy in future water supply planning.
- FCU now has a water supply modeling tool that can be used to conduct more detailed analyses of the WSVS risk scenarios or explore a broader range of uncertainties or operating conditions if desired. It can also be used to measure and compare the effectiveness of alternative water supply system improvements.

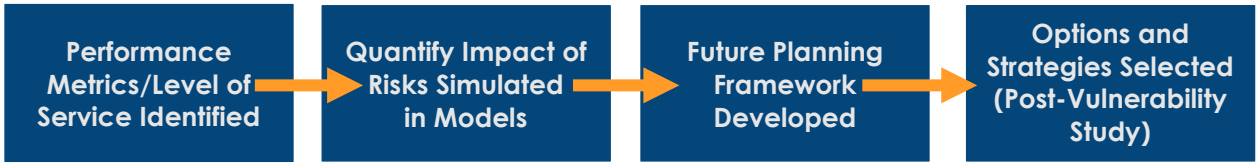
1.0 INTRODUCTION

The Fort Collins Utilities (FCU) Water Supply Vulnerability Study will explore a variety of future conditions related to climate, demands, and system risks with the goal of robustly assessing which of these future conditions present vulnerabilities for the FCU raw water system. The FCU water supply system model (FCM) will be used to simulate these many futures and is a key part of the study. As part of this process, the performance of the FCU system needs to be quantified using the FCM and then classified into satisfactory and unsatisfactory states. This will inform FCU on what future conditions create challenges for their water supply system.

There are two primary parameters needed to quantify satisfactory and unsatisfactory water supply system performance:

- *Performance Metrics* are specific measures characterizing the key features of a water supply system that are definable, measureable, representative, and unique. Examples of performance metrics could be maintaining a minimum volume of water in storage in July, years without customer restrictions, or use of Colorado-Big Thompson (CBT) supplies.
- *Level of Service (LOS)* goals are thresholds used to separate key performance metrics into satisfactory and unsatisfactory states. Examples of level of service goals could be triggering customer watering restrictions 5% of the time, or maintaining a volume of water equivalent to 1 year of demand in storage in 90% of Aprils.

The figure below shows how these performance metrics and level of service goals will be used in the Water Supply Vulnerability Study. First, they will be used to assess the impact of risks and uncertainties detailed in the *Risk Identification Technical Memorandum*. The outcome of that step will be identification of the risks and uncertainties to which the FCU system is most vulnerable. Then, these key risks and uncertainties will be used to develop future scenarios for use in the future planning framework. This future planning framework will then be used in a post-Vulnerability Study effort to evaluate options and develop future water supply strategies.



Ultimately, these performance metrics and LOS goals will be used to justify the conclusions of the Water Supply Vulnerability Study as well as the recommended options and strategies to FCU leadership and the public. Therefore, it is critical they capture how FCU assesses their own performance internally, as well as how external stakeholders and customers asses FCU's performance. This technical memorandum proposes the performance metrics and LOS goals for FCU's water supply system for these purposes.

2.0 BACKGROUND

The FCU Water Supply Vulnerability Study is a risk-based process using simulations of the FCU water resources system to evaluate system performance. In this type of plan, the definition of successful performance of the system is not pre-set (e.g. full demands are always met), but rather the model is allowed to operate the system freely and the results are used to inform what level of risk FCU is willing to take on in the future. In order to understand this risk, performance metrics and level of service goals must be established.

Prior water supply plans for FCU and throughout the water industry justified recommendations using the concept of firm yield, which assumes demands are met 100% of the time for a single future condition (e.g., one set of hydrology and one demand forecast). By moving away from firm yield and employing a suite of performance metrics, a risk-based approach can be used to develop recommendations around different hydrologic conditions, water demand, infrastructure reliability, and other factors. It also allows for multiple portfolios of water projects to be investigated to find those that are most effective across the widest variety of possible future conditions. In essence, this approach better answers the question "What level of performance can or should we afford?" by exploring the tradeoff between performance and cost of water supply improvements.

2.1 DEFINITIONS

As previously stated, there are two components to measuring system performance: performance metrics and LOS goals. Performance metrics are specific measures characterizing performance of key water supply system features (e.g. total storage, flow through a pipeline, yields from a watershed). Performance metrics are definable, measureable, representative, and unique within the FCM. Most importantly, performance metrics reflect how FCU staff measures and assesses water supply system performance.

Performance metrics are traditionally presented using the terms reliability, resilience, and vulnerability (RRV) but can also be calculated using statistical measures such as the mean, median, maximum, or minimum. The formal definitions of reliability, resilience, and vulnerability are:

- *Reliability* is the probability that the water supply system feature is in a satisfactory state, answering the question "how often".
- *Resilience* is the probability that a time period when the water supply system feature is in an unsatisfactory state is followed by a time period when the water supply system feature is in the satisfactory state, answering the question "how long".
- *Vulnerability* is the severity or magnitude of the unsatisfactory state for the water supply system feature, answering the question "how severe".

LOS goals separate values of key performance metrics into satisfactory and unsatisfactory states, ultimately justifying conclusions and/or recommendations from a water supply study. LOS goals are most effective when they reflect how water supply system performance is communicated to management and are in alignment with governing policy.

2.2 EXISTING MEASURES OF PERFORMANCE

Prior to this analysis, any current measures of water supply system performance adopted by Fort Collins Utilities were identified. The Water Supply and Demand Management Policy Report 2012 Update listed governing policy for various aspects of the FCU water system such as climate, water supply, conservation, and water quality. Of these, one was applicable to water supply reliability. This existing water supply reliability criterion has three components:

1. FCU will meet a planning level demand of 150 gpcd;
2. during at least a 1-in-50 year drought;
3. while maintaining 20% of annual demand in storage.

These components represent a current level of service goal, as futures that do not meet this condition are considered unsatisfactory. FCU has set policies around other aspects of water system operation as well, such as water use efficiency, water quality, and regional cooperation that could be considered when developing LOS goals and performance metrics.

3.0 PERFORMANCE METRICS

Performance metrics were identified during a workshop conducted with FCU staff and the consulting team. **Table 3.1** lists the identified performance metrics for the FCU water supply system that will be used for the Water Supply Vulnerability Study.

Table 3.1 - Identified performance metrics

	ID	Performance Metric	Description
Meeting Customer Demands	1	Minimum Met Annual Demand	The minimum annual demand met in acre-ft/year across a simulation
	2	Meeting Indoor Demands	The RRV of meeting indoor demands across a simulation
	3	Meeting Reduced Demands	The RRV of meeting demands after they have been reduced by restrictions
	4	Annual Response Level 1 Restrictions	The R&R of when customers are in Response Level 1 restrictions across a simulation
	5	Annual Response Level 2 Restrictions	The R&R of when customers are in Response Level 2 restrictions across a simulation
	6	Annual Response Level 3 Restrictions	The R&R of when customers are in Response Level 3 restrictions across a simulation
	7	Annual Response Level 4 Restrictions	The R&R of when customers are in Response Level 4 restrictions across a simulation
Maintaining Supply in Storage	8	0.1-Year of Demand in System Storage	The RRV of maintaining 0.1-Year of Demand in Storage at all times during a simulation
	9	0.2-Year of Demand in System Storage	The RRV of maintaining 0.2-Year of Demand in Storage at all times during a simulation
	10	0.3-Year of Demand in System Storage	The RRV of maintaining 0.3-Year of Demand in Storage at all times during a simulation
	11	0.4 Year of Demand in System Storage	The RRV of maintaining 0.4-Year of Demand in Storage at all times during a simulation
	12	0.5 Year of Demand in System Storage	The RRV of maintaining 0.5-Year of Demand in Storage at all times during a simulation
	13	0.6 Year of Demand in System Storage	The RRV of maintaining 0.6-Year of Demand in Storage at all times during a simulation
	14	0.7 Year of Demand in System Storage	The RRV of maintaining 0.7-Year of Demand in Storage at all times during a simulation
	15	0.8 Year of Demand in System Storage	The RRV of maintaining 0.8-Year of Demand in Storage at all times during a simulation
	16	0.9 Year of Demand in System Storage	The RRV of maintaining 0.9-Year of Demand in Storage at all times during a simulation
	17	1.0 Year of Demand in System Storage	The RRV of maintaining 1.0-Year of Demand in Storage at all times during a simulation
	18	Minimum Storage – YOD	Minimum YOD storage volume during a simulation
	19	Minimum Storage – acre-feet	Minimum acre-foot storage volume during a simulation
Operational	20	Lost Water Due to Water Quality Requirement	Statistical quantifications (average, max, count) of annual volume of water lost due to water quality blending requirements
	21	Lost Water Due to Insufficient Storage	Statistical quantifications (average, max, count) of annual volume of useable water lost due to insufficient storage capacity
	22	Meeting Reusable Demands	The RRV of meeting reusable demands

R&R is Reliability and Resilience

RRV is Reliability, Resilience, and Vulnerability

Seven performance metrics were identified that capture the ability of the water supply system to meet customer demands. FCU has an adopted Water Supply Shortage Response Plan that specifies how FCU will restrict customer water use during periods of water shortage, typically observed during droughts. This Water Supply Shortage Response Plan specifies four response levels, summarized in **Table 3.2**, that are determined based on water supply shortage. Water supply shortage, for this purpose, is the difference between forecasted demand and forecasted supply prior to runoff season. A performance metric was specified for the reliability and resilience of each of these response levels. The RRV of meeting demands after they have been reduced by restrictions will also be a performance metric. The RRV of always meeting FCU indoor demands is another demand-based performance metric, as inability to meet all indoor customer demands represents a critical system failure. Finally, the minimum met annual demand was identified as a performance metric as FCU governing policy specifies a minimum gallons per-capita-day demand that must be met by the water supply system.

Table 3.2 - Water Supply Shortage Response Plan elements

Response Level One	Enacted when water supply shortage is less than 10%. Outdoor irrigation allowed only two days per week.
Response Level Two	Enacted when water supply shortage is between 11% and 20%. Outdoor irrigation allowed only one day per week.
Response Level Three	Enacted when water supply shortage is between 21% and 30%. Outdoor irrigation allowed only one day per week with a 2-hour time limit on watering.
Response Level Four	Enacted when water supply shortage is greater than 30%. No outdoor irrigation allowed

Twelve performance metrics were identified related to water supply system storage. These performance metrics quantify the RRV of maintaining a certain volume of water in storage at all times, with storage volumes represented as percentages of years of annual demand (YOD). Quantifying the RRV of maintaining increasing volumes of storage in the water supply system is important as storage is the primary way FCU can reduce the risk of major customer impacts during emergency conditions (e.g. natural disasters, unplanned outages, wildfires). Storage volumes from 10% to 100% of annual demand in 10% increments will be quantified using RRV performance metrics. Additionally, the minimum storage across a simulation (reported out both in acre-feet values and YOD) will be tracked to ensure governing policy is met.

Three performance metrics were identified that capture operational goals. The first quantifies statistically the volume of water lost due to water quality blending requirements. FCU's current system is operated by blending water supply sources to meet a minimum level of water quality prior to treatment. This operational requirement occasionally results in water that cannot be used because there is insufficient high-quality water to blend with and the treatment plants do not have the ability to treat water from the available sources. Another quantifies statistically the volume of water lost due to demands being less than supply and available storage being insufficient to make up the difference. The final metric quantifies the RRV that FCU's water supply system can meet the reusable demands as laid out in the Reuse Plan. If FCU is unable to meet these demands, it could result in violation of this contract and a reduction of supplies available to FCU.

Overall, 20 performance metrics were identified by FCU staff that capture a variety of features of the water supply system. These performance metrics will be calculated for every simulation completed per the process described in Section 5.0.

4.0 LEVEL OF SERVICE GOALS

The performance metrics described in Section 3.0 were evaluated to determine which are applicable as level of service goals and what the thresholds for level of service are. Seven performance metrics were included as level of service goals, which are shown in **Table 4.1**. Level of service goals were selected to align with FCU governing policy.

The selected level service goals are primarily customer-facing, such that futures that significantly impact customers will be considered unsatisfactory. Any future for which indoor demands are not always met will be unsatisfactory. FCU accepts future conditions where customers are in any type of water restriction every 1 in 10 years (90% reliability) with more impactful restraints occurring less frequently. To comply with governing policy, at least 20% of annual demand must be maintained in storage at all times for a future to be considered satisfactory. Finally, all reusable demands must be met 100% of the time[1].

Table 4.1 - Selected Level of Service Goals

ID	Performance Metric	Level of Service Goal	Justification
2	Meeting Indoor Demands	100% Reliability	Governing policy, greatest customers impact
4	Annual Response Level 1 Restrictions	1 in 10 Years (90% Reliability)	Perceived customer risk tolerance
5	Annual Response Level 2 Restrictions	1 in 25 Years (96% Reliability)	Perceived customer risk tolerance
6	Annual Response Level 3 Restrictions	1 in 100 Years (99% Reliability)	Perceived customer risk tolerance
7	Annual Response Level 4 Restrictions	1 in 500 Years (99.8% Reliability)	Perceived customer risk tolerance
9	0.2-Year of Demand in System Storage	100% Reliability	Governing policy
20	Meeting Reusable Demands[1]	100% Reliability	Reuse Plan Agreement

These LOS goals will be used in the Water Vulnerability Study to separate futures for which water supply system performance is satisfactory from those for which it is unsatisfactory. However, these LOS goals are a policy decision, and one potential water resources strategy is to change the LOS goals or thresholds to take on more risk. For example, FCU could lower the storage requirement from 0.2 to 0.1 years of demand in storage with 100% reliability, thereby improving performance (relative to the relaxed objective) but increasing the risk that sufficient water would not be available during an emergency. This question will be addressed as part of a later study.

[1] The reuseable demand level of service goal is still in development, this TM will be updated accordingly when this level of service goal is determined.

5.0 MODELING IMPLEMENTATION

The identified performance metrics from Section 3.0 will be incorporated into the FCM data management system (DMS). Each simulation completed will have the corresponding performance metrics automatically calculated, tracked, and stored in the central database. **Table 5.1** summarizes the procedure for calculating these performance metrics. With the exception of the Minimum Storage metric, all performance metrics will be calculated monthly but reported annually. An example of this, using the "0.5 YOD in System Storage" metric, the total system storage will be calculated at the end of each month during a simulation. If any months during a water year have total system storage below 0.5 YOD, then the water year will be noted as a failure. The resulting performance metric value will be the percent of simulated water years in which any month had total system storage below 0.5 YOD. The "Lost Water Due to Water Quality Requirement" performance metric will sum the lost water across a water year, then apply the corresponding statistical measure.

Table 5.1 - Implementation of Metrics in FCM and DMS

ID	Performance Metric	Calculation(s)	Representative FCM Object
1	Minimum Met Annual Demand	Minimum	CityDem, LCUsu, LCUwc
2	Meeting Indoor Demands	RRV	LCUsu, LCUwc +Pre-processing for CityDem or change in model to reflect indoor + outdoor split
3	Meeting Reduced Demands	R&R	LCUsu, LCUwc, CityDem
4	Annual Response Level 1 Restrictions	R&R	0-10% shortage (projected + shortage reserve factor, triggers for time period. What is quota today (yield/shares), snowpack today (streamflow today) – maybe look at future inflow over next 6 months.
5	Annual Response Level 2 Restrictions	R&R	Same as 4, but for 10-20% shortage
6	Annual Response Level 3 Restrictions	R&R	Same as 4, but for 20-30% shortage
7	Annual Response Level 4 Restrictions	R&R	Same as 4, but for >30% shortage
8	0.1-Year of Demand in System Storage	RRV	Carryover StoRight (only if carryover is on), Horsetooth StoRight, Halligan StoRight, JoeWright StoRight
9	0.2-Year of Demand in System Storage	RRV	
10	0.3-Year of Demand in System Storage	RRV	
11	0.4 Year of Demand in System Storage	RRV	
12	0.5 Year of Demand in System Storage	RRV	
13	0.6 Year of Demand in System Storage	RRV	
14	0.7 Year of Demand in System Storage	RRV	
15	0.8 Year of Demand in System Storage	RRV	
16	0.9 Year of Demand in System Storage	RRV	
17	1.0 Year of Demand in System Storage	RRV	
18/19	Minimum Storage (acre-feet and YOD)	Minimum	
20	Lost Water Due to Water Quality Requirement	Non-zero Average, Frequency, Maximum	Poudre Avail – HT used – Reuse Plan Reqts, limited to max of HT used + Reuse Plan. Post processing calculation
21	Lost Water Due to Insufficient Storage	Non-zero Average, Frequency, Maximum	In Development
22/23	Meeting Reusable Demands	RRV	LCUwc[2]

R&R is Reliability and Resilience

RRV is Reliability, Resilience, and Vulnerability

[2] The reuseable demand FCM implementation is still in development, this TM will be updated accordingly when this FCM implementation is determined.

6.0 SUMMARY

As part of the FCU Water Supply Vulnerability study, performance metrics and LOS goals were identified for implementation in the FCM and DMS. FCU staff identified 20 performance metrics that capture a variety of demand, storage, and operational measures. Of these 20, eight performance metrics were identified for use as LOS goals. These LOS goals and performance metrics will be used to both asses the vulnerability of the water supply system to future conditions as well as ultimately compare different potential options or strategies for addressing the vulnerabilities.

Appendix B WATER SUPPLY SYSTEM RISKS IDENTIFICATION TECHNICAL MEMORANDUM

City of Fort Collins Utilities
Water Vulnerability Study

Technical Memorandum

Water Supply System Risks Identification

Date: May 8, 2018
From: Neil Stewart, Chip Paulson, Lisa Fardal
To: Fort Collins Utilities

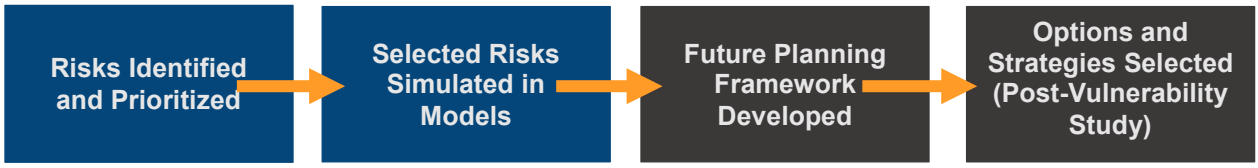
Stantec

1.0 INTRODUCTION

The Fort Collins Utilities (FCU) water supply system spans many watersheds and is comprised of a variety of infrastructure components, some owned and operated by FCU and some owned and operated by other entities. In this past, aspects of this system have been compromised by various events or conditions that impacted FCU's ability to meet customer needs. These events and conditions that have occurred before, as well as emerging ones, will continue to threaten FCU's water supply system in the future.

As part of the Fort Collins Water Vulnerability Study, a future planning framework is being developed that FCU will use to develop a robust plan to meet level of service goals in an uncertain future. This framework will include planning for events and conditions that could negatively impact Fort Collins' water supply system and its ability to meet customer needs.

Therefore, a key element of the Water Vulnerability Study is identification of future risks and uncertainties to be included in FCU's overall water supply planning process. The figure below shows how the information presented in this technical memorandum (TM) fits within the larger Water Vulnerability Study. The TM summarizes the identified risks and uncertainties, the process used to prioritize them, and how the prioritized risks were simulated in the Fort Collins water resources modeling system. Later analysis will develop the future planning framework and a separate study will be conducted to evaluate these options and strategies.



The purpose of the risk and uncertainty assessment was to look out 50 years and forecast events that could adversely affect FCU water supplies or infrastructure. The 50-year timeframe is the period adopted for the Water Vulnerability Study. It is recognized that anticipating conditions that may exist 50 years in the future is highly speculative. However, for purposes of the Water Vulnerability Study it is appropriate to investigate a broad range of possible future conditions to determine which conditions would stress the performance of the current water supply system.

The areal scope of the Water Vulnerability Study includes source water areas and infrastructure upstream of the FCU water treatment plant. In addition to local Poudre River Basin supplies, the scope includes supply derived from the Colorado-Big Thompson (C-BT) Project, operated by

the U.S. Bureau of Reclamation (Bureau) and the Northern Colorado Water Conservancy District (Northern). Therefore risks and uncertainties were identified by both FCU staff and Northern staff. These were two separate processes, as described later in this TM.

Identified risks and uncertainties were organized in the following categories that span the various aspects of the FCU water supply system:

- ***Climate and Hydrology*** risks relate to weather variability and other hydrologic factors, both short- and long-term, that can impact the potential yields from a watershed.
- ***Watershed*** risks relate to physical watershed conditions that can impact the yields available to FCU.
- ***Operational and Infrastructure*** risks relate to how FCU delivers physically and legally available water to its treatment facilities.
- ***Administrative and Legal*** risks relate to conditions, regulations, or policies that could impact the legal allocation or availability of water supplies.
- ***Demand*** risks relate to changes in required volume, timing, and quality of water that will need to be delivered to water treatment facilities to meet customer needs

These identified risks were then scored as part of the prioritization process. Individual risks were scored by assigning a 1-5 score for likelihood (possibility of the risk or uncertainty occurring) and impact (consequences to the FCU/C-BT water supply system if the risk or uncertainty were to occur) according to the definitions below. The composite score (likelihood times impact) was then used to help prioritize risks.

Score	Likelihood Definition	Impact Definition
1	***Rare*** – the risk will only occur in exceptional circumstances.	***Insignificant*** – If the risk occurs the impact to the water supply system would be negligible.
2	***Unlikely*** – the risk will occur in occasional circumstances.	***Minor*** – If the risk occurs the impact to the water supply system would be minimal.
3	***Possible*** – the risk will occur in some circumstances.	***Moderate*** – If the risk occurs there would be a noticeable impact to the water supply system.
4	***Likely*** – the risk will occur in a majority of circumstances.	***Major*** – If the risk occurs there would be substantial impact to the water supply system.
5	***Almost Certain*** – the risk will occur in almost all circumstances or is imminent.	***Extreme*** – If the risk occurs there would be extensive or catastrophic impact to the water supply system or customers.

2.0 FORT COLLINS UTILITIES' WATER SUPPLY SYSTEM RISKS

Risks and uncertainties to the FCU water supply system were identified by staff members representing a variety of groups within the organization during a half-day workshop. Workshop attendees included representatives from water supply, water treatment, demand and conservation, watershed management, legal, and water operations groups. These same staff members scored the risks as a group using the rubric described in Section 1.0 based on their perceptions and professional judgment. The adopted score was the consensus of the workshop participants. Therefore, results of the scoring process are presented as a *perceived* threat to the water supply system, as the actual impact to the water supply system will be quantified using simulation later in the Water Vulnerability Study. This section summarizes all risks and uncertainties identified and then describes how these identified risks and uncertainties were prioritized for simulation.

2.1 SUMMARY OF ALL RISKS

Identified risks and uncertainties are summarized around five categories that represent different aspects of a water supply system: Climate and Hydrology, Watershed, Operations and Infrastructure, Legal and Administrative, and Demand.

2.1.1 Climate and Hydrology Risks

Table 2.1 lists the five risks and uncertainties associated with the climate and hydrology in the watersheds contributing to the FCU water supply system. For purposes of this evaluation, climate change assumptions in the Fort Collins region and water source areas were based on general findings of past climate change studies for Colorado and the Front Range region. These studies suggest future climate will be characterized by increased temperature; however, the impact on precipitation is unclear as it may increase or decrease.

- C1 - Longer duration droughts (e.g. multiple years with below average yields or back-to-back severe droughts) are perceived as the biggest threat to FCU's water supply system as these types of droughts can occur under the current climate, but would also be exacerbated under climate change or conditions of increased climate variability as seen in paleohydrology data pre-dating the period of observed records.

- C2 - Change in runoff timing (peak runoff occurring earlier and/or over a shorter period of time) is predicted by climate change studies for Colorado, and was perceived as a high threat due to a combination of limited storage in FCU's system, capacities of diversion systems, and highly specific timing of certain decreed water rights. Less runoff would be captured when higher peaks occur because more flow would exceed the diversion structure capacity and bypass the diversion. Limited storage space makes it more difficult to meet demands late in the season during dry years when runoff has subsided earlier than historically. Finally, certain water right decrees for FCU only allow diversions within fixed periods early in the runoff season, and these decrees would yield less water in the future than they do currently if runoff begins earlier and occurs outside of the allowable diversion window.

- C3 - One anticipated impact of warmer temperatures due to climate change in the study area would be a shift in precipitation type to more rainfall and less snow. A change in precipitation type was perceived as a high threat as the “snowpack reservoir” would be reduced and FCU would be unable to compensate for that in their system due to a lack of storage.
- C4 – Another anticipated impact of climate change in the study area is a change in the frequency and magnitude of precipitation events. Precipitation events could be less frequent, but more intense when they do occur, such as the September 2013 event. This increases the risk of flooding.
- C5 - A longer growing season due to warmer temperatures was not perceived as a significant threat from a hydrology perspective because agricultural users in the Poudre River Basin already use their full decreed water rights. Additionally, research shows a warming climate may actually reduce agricultural productivity (and hence water use) due to increased heat stress on plants. An analysis conducted by FCU concluded that their system is not sensitive to changing agricultural demands.

Table 2.1 – Identified Climate and Hydrology Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
C1	Longer duration droughts	Multi-year and/or more severe droughts occur in the future that are not captured in the observed record.	5	4	20
C2	Changes in runoff timing	Early higher runoff and lower late-season baseflow reduces yield from volumetric decrees that list specific diversion dates.	4	4	16
C3	Change in precipitation type	More precipitation falls as rain instead of snow during the Fall and Spring.	4	4	16
C4	Changes in frequency/ magnitude of precipitation events	Precipitation events, particularly summer rainstorms, become less frequent and more intense.	4	4	16
C5	Longer growing season	Warmer climate increases growing season in Spring and Fall, changing potential water rights calls and increasing irrigation demand.	4	2	8

2.1.2 Watershed Risks

Table 2.2 lists the seven risks and uncertainties identified that would impact the watershed aspect (i.e., source water areas) of the FCU water supply system.

- W1 - Wildfires were perceived as the most significant threat to watersheds due to their broad impacts and increased likelihood in a warmer climate. In the short term wildfires have significant water quality impacts that could render yields from a particular watershed untreatable, and could cause an increase in sediment loads that would impact diversions or other conveyance systems. In the longer-term, water quality impacts would persist and may require upgrades to water treatment plants, and hydrograph changes would be persistent until the vegetation recovers.

- W2 - Forest health degradation was also perceived as a high threat to watersheds. In the future, one of the primary causes of forest health degradation is expected to be pine beetle kill and impacts of other similar pests as warmer temperatures allow for infestations to impact broader areas of forest. Other potential causes could be warmer temperatures and more frequent droughts which would stress vegetation more significantly. Regardless of the cause, reduced forest health would cause changes to the hydrograph, increased sedimentation, and lower water quality. These impacts would occur slowly over many years; however, their impacts would be difficult to effectively mitigate. Additionally, degraded forest health would increase the risk of wildfires. The uncertainty of the impact of forest health on FCU water supplies is amplified by the fact that 90% of forests in source watersheds are managed by the Federal Government and thus, are outside Fort Collins' control.

- W3 - Development in watersheds such as expanded communities, denser development, oil and gas development, mining, and new road construction was perceived as a moderate threat to watersheds. These activities could cause both long-term impacts, such as reduced water quality due to road traffic and more septic systems, and short-term impacts, such as contamination events due to spills or vehicle accidents. The pressure for these kinds of development in the FCU contributing watersheds is currently relatively modest, largely because there is limited land available for development and most of the watershed is owned and managed by natural resource agencies as described above.

- W4 - Increased atmospheric deposition of particulates and pollutants within FCU watersheds is a possible outcome of a drier climate due to changes in vegetation land cover in the Western U.S. This trend has already been observed in Colorado's mountains. Increased atmospheric deposition was perceived as a moderate threat due to the potential for the emergence of new water quality issues in previously pristine high-alpine bodies of water and streams, such as algal blooms or long-term diminished water quality.

The remaining risks and uncertainties listed in **Table 2.2** were not perceived as significant threats to the water supply derived from the FCU source water watersheds.

Table 2.2 - Identified Watershed Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
W1	Wildfires	Wildfires occur, causing a variety of impacts on water quality, runoff, and threats to infrastructure.	5	4	20
W2	Forest Health Degradation	Forested area health decreases due to beetle kill, pollution, warming climate, etc.	4	4	16
W3	Development in Watersheds	Land development in watersheds (recreation, residential, O&G, mining) increases risk of water quality contamination.	4	3	12
W4	Atmospheric Deposition	Increased levels of contaminants in bodies of water and forests lead to new water quality issues.	5	2	10
W5	Deficiencies in Federal land Management	Federally owned land, which comprises nearly all of the watersheds, is poorly managed against wildfires or to promote forest health.	2	3	6
W6	Abandoned Mine Runoff	Runoff from abandoned mines leads to decreased water quality. Few mines exist in FCU watersheds.	1	4	4
W7	Privatization of Public Lands	Lands owned by the federal government are transferred to private entities, increasing development potential.	1	4	4

2.1.3 Operations and Infrastructure Risks

Table 2.3 lists the 16 risks and uncertainties identified that would impact the operations and infrastructure aspect of the FCU water supply system.

- O1 and O2 - An outage of either the 24-inch or 27-inch raw water delivery pipelines from the Poudre River were perceived as an extreme threat to the water supply system. Without one of these pipelines, FCU would have limited capacity to convey Poudre River supply to its Soldier Canyon water treatment plant. The pipelines are in high risk zones for landslides and some sections are underneath the river, which in the event of a major flood could expose the pipelines or fill them with sediment. Some pipeline segments are extremely hard to access, making repairs costly and time-intensive.

- O3 - Algal blooms were also perceived as a significant threat to the water supply system. FCU has experienced problems with algal blooms in its source water in the past, and a warmer future climate would increase the likelihood of these events. Algae outbreaks could have a minor impact of causing maintenance issues in impacted reservoirs or river reaches, potentially affecting operations. More significantly, large algal blooms in reservoirs could have severe impacts to water quality that FCU's water treatment plant would currently be unable to treat. Therefore, in these events, FCU would be unable to use the impacted supply during high risk months (approximately June to October). Horsetooth Reservoir is the most vulnerable storage facility, supplying water to the FCU system, to this type of algal bloom impact.

- O4, O5, and O6 - Three infrastructure outages were perceived as high threats to the water supply system: Michigan Ditch, Horsetooth Reservoir Intake, and Chambers Reservoir. Without Michigan Ditch, FCU cannot convey transmountain supply to its Front Range collection system. Without the Horsetooth Reservoir intake, FCU cannot utilize its Colorado-Big Thompson (CBT) shares stored in Horsetooth Reservoir. There is currently no system redundancy for delivering FCU water from Horsetooth Reservoir. Finally, most FCU water supplies are generated above Chambers Reservoir but must pass through the reservoir before reaching FCU's diversion facilities. Chambers Reservoir is not owned by FCU and is at a higher risk of failure due to the potential for underfunded maintenance which may result in sudden operational changes that impact FCU.

The remaining risks were not perceived as significant threats. However, some of the remaining risks are low likelihood (score of 1 or 2) and high impact (score of 4 or 5). These risks, which could have significant impact if they were to occur, were further evaluated when risks were prioritized; this is discussed in Section 2.2.

Table 2.3 - Identified Operations and Infrastructure Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
O1	Outage - 24 Pipeline	Short term outage due to flooding, landslides, wildfire, etc.	5	5	25
O2	Outage - 27 Pipeline	Short term outage due to flooding, landslides, wildfire, etc.	5	5	25
O3	Algal Blooms	Algal blooms in storage reservoirs and rivers increases water quality issues and potential treatment problems.	5	4	20
O4	Outage - Michigan Ditch	Short term outage due to flooding, landslides, wildfire, etc.	5	3	15
O5	Outage - Horsetooth Reservoir Outlet	Short term outage of reservoir outlet and intake to WTP; higher risk due to lack of redundancy.	3	5	15
O6	Outage - Chambers Reservoir	Short term outage due to flooding, landslides, wildfire, etc.	3	4	12
O7	Outage - Munroe Canal	Short term outage due to flooding, landslides, wildfire, etc.	3	3	9
O8	Outage - Joe Wright Reservoir	Short term outage due to flooding, landslides, wildfire, etc.	2	4	8
O9	Shared infrastructure - Chambers Reservoir	Lack of control of operations could lead to issues with delivering water.	2	4	8
O10	Outage - Meadow Creek Reservoir	Short term outage due to flooding, landslides, wildfire, etc.	3	2	6
O11	Outage - Pleasant Valley Pipeline	Short term outage due to flooding, landslides, wildfire, etc.	1	4	4
O12	Shared infrastructure - Munroe Canal	Lack of control of operations could lead to issues with delivering water.	1	4	4
O13	Shared infrastructure - Pleasant Valley Pipeline	Lack of control of operations could lead to issues with delivering water.	1	4	4
O14	Sediment Loading - Reservoirs	Loss of capacity in reservoirs due to increased sediment loads.	3	1	3
O15	Freeze/Thaw Cycles	Initial freezing stages impact water quality, ice coming down the river could impact operations.	3	1	3
O16	Shared infrastructure - Meadow Creek Reservoir	Lack of control of operations could lead to issues with delivering water.	1	1	1

2.1.4 Legal and Administrative Risks

Table 2.4 lists the eight risks and uncertainties identified that would be associated with the legal and administrative aspects of the FCU water supply system.

- A1 - New regulations, including both water quality and environmental regulations, were perceived as a significant risk. New or more stringent water quality standards or environmental permitting requirements could affect FCU water resources in several different ways. For example, new environmental regulations calling for increases or changes to environmental flows in the Poudre River watershed would need to be made up from existing water uses, which could impact the yields available to FCU. New water quality regulations could preclude use of existing water sources without additional treatment and may limit FCU's ability to blend Poudre River water with CBT water, impacting operations. More stringent permitting requirements could make it more difficult to develop new water supplies, including transfer of agricultural water rights.

- A2 - Increased demands by other water users in the Poudre River basin were perceived as a high threat to the water supply system. Regional water demands could increase either through new urban development or through changes in agricultural crop selection or irrigation practices. This risk could be manifested both as an increase in competition for new water rights and supplies as well as increasing use of existing water rights which could impact the yields available to FCU. Also, since FCU shares much of its water collection and storage infrastructure with other entities, other users may have conflicting operational objectives which may impact yields to FCU.

- A4 - Another potential future condition perceived as a significant risk to the water supply system was a change in state administration of water rights. Since water rights are based on an assumed hydrology, and that hydrology may change in response to climate variability, the way Colorado administers water rights under the prior appropriation doctrine could change. For example, assumed shrink values for conveying water through specific river reaches may increase to account for greater losses, resulting in lower yields for FCU. Also, when water rights are transferred, the adjudicated yield from those rights may be reduced by the state, impacting the yield FCU receives from future water rights.

- A9 – The Reuse Plan, which results in FCU receiving 1,900 acre-feet of firm supply, relies on the continued operation of the Rawhide Energy Station, owned and operated by Platter River Power Authority (PRPA). In the future if PRPA no longer requires Rawhide Energy Station and takes it offline, this will end the Reuse Plan and remove the corresponding 1,900 acre-feet of firm supply from FCU's water supply portfolio. Also in multi-year drought events, the yields from the Reuse Plan are reduced and or eliminated, impacting FCU's water supply portfolio.

- A3 - Since FCU receives a significant amount of yield from the CBT project and the operation of its system is designed around how Northern operates this system, changes to that operation are perceived as a risk to FCU. One possible trigger for this change would be a continuation of the recent trend of a toward more municipal CBT ownership

and less agricultural ownership. This could affect the Northern Board's process for setting the annual CBT quota, which determines how much CBT water is available to FCU and other CBT allottees. Additionally, the current Carryover Program or Regional Pool Program, which offers more flexibility to municipal CTP share owners in how they manage their water resources, could change or be eliminated by future Northern Boards. Any of these CBT changes could impact FCU operations.

The remaining risks and uncertainties in **Table 2.4** were not perceived as being a significant threat to FCU water supply system.

Table 2.4 - Identified Legal and Administrative Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
A1	New Regulations - water quality and environmental	New regulations (either federal or state) impact availability of yields from existing water rights.	5	4	20
A2	Increased Basin Demands	Higher demands across the entire Poudre River basin (due to climate change/population growth) impact use of water rights.	5	3	15
A4	Changing state administration	Policies around state water administration change, impacting yields from water rights.	5	3	15
A9	Elimination or Interruption of Reuse Plan	Platte River Power Authority decommissions Rawhide Energy Station, effectively eliminating the need for the Reuse Plan. In multi-year droughts, water from the Reuse Plan is reduced or unavailable.	4	3	12
A3	Changes to Northern Water CBT Operations	Allocation of CBT water through setting of the quota, and ways in which CBT water can be managed, changes in the future.	4	3	12
A5	Water Court Risks to existing decrees	Existing water rights are challenged in court, potentially changing their availability.	5	2	10
A6	New Regulations - Endangered Species	New regulations impact availability of yields from existing water rights and ability to permit new projects. Mostly impacts new projects.	3	3	9
A7	Public Trust Doctrine	Colorado water law is fundamentally changed, eliminating the prior appropriation system.	1	5	5
A8	Yields reduced in future change cases	Less water is realized from future water rights as assumed yields are greater than actual. FCU doesn't anticipate acquiring many new water rights so risk is low.	4	1	4

2.1.5 Demand Risks

Table 2.5 lists the eight risks and uncertainties identified that are related to demands on the water supply system.

Three demand-related risks and uncertainties were perceived as being a high threat to the water supply system.

- D1 - There is currently significant development pressure in the north Front Range region driving growth in and around Fort Collins. While the current FCU service area is mostly built-out, additional growth within or expansion of that service area could increase demands and change operations.
- D2 - Over the last 15 years, per capita water use in Fort Collins has steadily declined due to a variety of factors such as increased indoor fixture efficiency, changes to outdoor landscaping and irrigation, and an effective City water conservation program. This has created a new relationship between demand increases and population growth. The same trend has been experienced throughout Colorado and the Western U.S. How long this trend will continue is unknown. Reduced per capita demand has the benefit of stretching existing water supplies, although it has adverse impacts on utility revenue. Lower per capita demands could potentially reduce the demand savings achievable from future water use restrictions during droughts or water shortage emergencies. This phenomenon is also known as demand hardening, and could affect how Fort Collins plans for future water shortages.
- D3 - New development could be considerably different than past development. Residential development could have greater density and less landscaped area if current trends persist. Significant future development could consist of redevelopment in high-income areas. This includes higher densities, mixed uses within a single building, and different outdoor space uses. This would change how future demand is tied to residential population and commercial activity, leading to greater uncertainty in predicting the impact of population and economic growth on water use.

Three uncertainties tied to how climate change may impact demands were also perceived as being moderately impactful to the water supply system.

- D6, D8, and D9 - Overall temperature increases would increase peak summer demands and extend high demand periods further into the spring and fall. This could be coupled with increased precipitation in the form of rain, which may also change demand patterns. These demand increases would occur both for FCU and for other water providers in the region, stressing water supplies. Finally, if summer precipitation events become less frequent but more intense, this may lead to an overall increase in demand as customers need to irrigate more frequently.

The remaining risks and uncertainties in **Table 2.5** were not perceived as being a significant threat to FCU's water supply system.

Table 2.5 - Identified Demand Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
D1	Service area growth and Regionalization	Ft. Collins expands its service area or enters into agreements to provide water to regional entities.	3	5	15
D2	Water use changes	Decrease in per capita use continues and how water is used (e.g. indoor vs. outdoor) changes.	5	3	15
D3	Development Uncertainty	The composition of development in service area (e.g. density, type, outdoor area) is different that past.	5	3	15
D6	Hotter summer changes irrigation	A warmer climate increases the length of the irrigation season and hotter days increase demand during the summer.	4	3	12
D8	Change in precipitation type	More precipitation falls as rain instead of snow during the Fall and Spring.	4	3	12
D9	Changes in frequency/ magnitude of precipitation events	Precipitation events become less frequent and more intense.	4	3	12
D4	Landscape Changes	Changes in outdoor landscaping (e.g. xeriscape) change demands from past.	3	3	9
D5	Decreased water restriction effectiveness	Watering restrictions become less effective at temporarily reducing demands.	3	3	9
D7	New Large Users	A new, non-regional water user is brought on in the service area.	3	2	6
D10	Changes to Existing Obligations	Existing large water contracts change or end.	3	1	3

2.2 PRIORITIZED RISKS

Figure 2.1 plots all risks and uncertainties identified by FCU as a circle on a grid corresponding to their likelihood and impact scores, with the impact score as columns and the likelihood score as rows. The color of the circle corresponds to the category the risk or uncertainty originates from and the label is the ID of the risk or uncertainty. In total, 46 risks and uncertainties were identified by FCU.

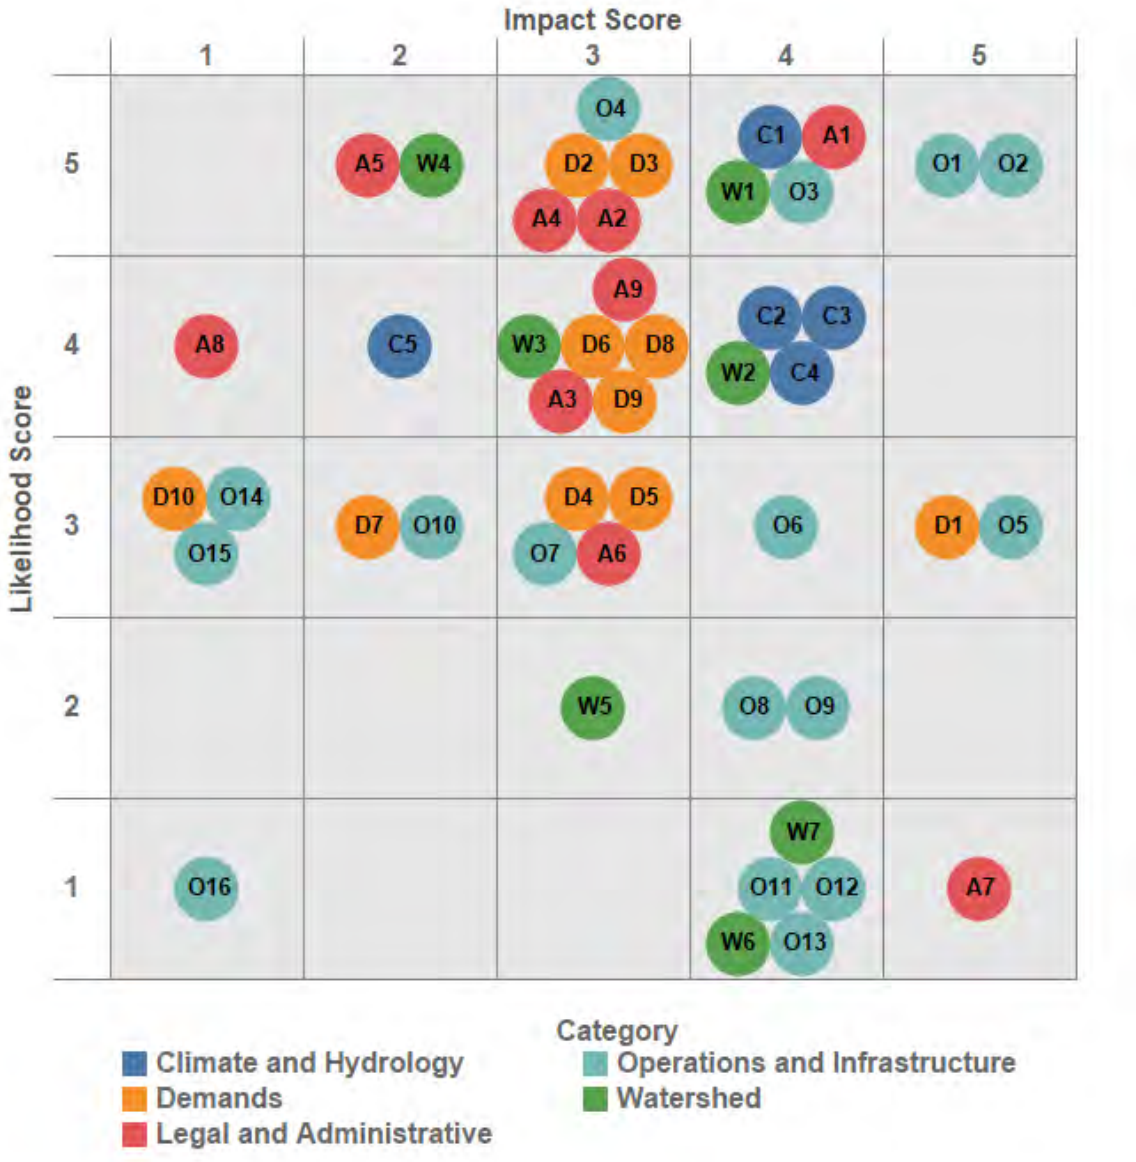


Figure 2.1 – Risks and uncertainties identified by FCU

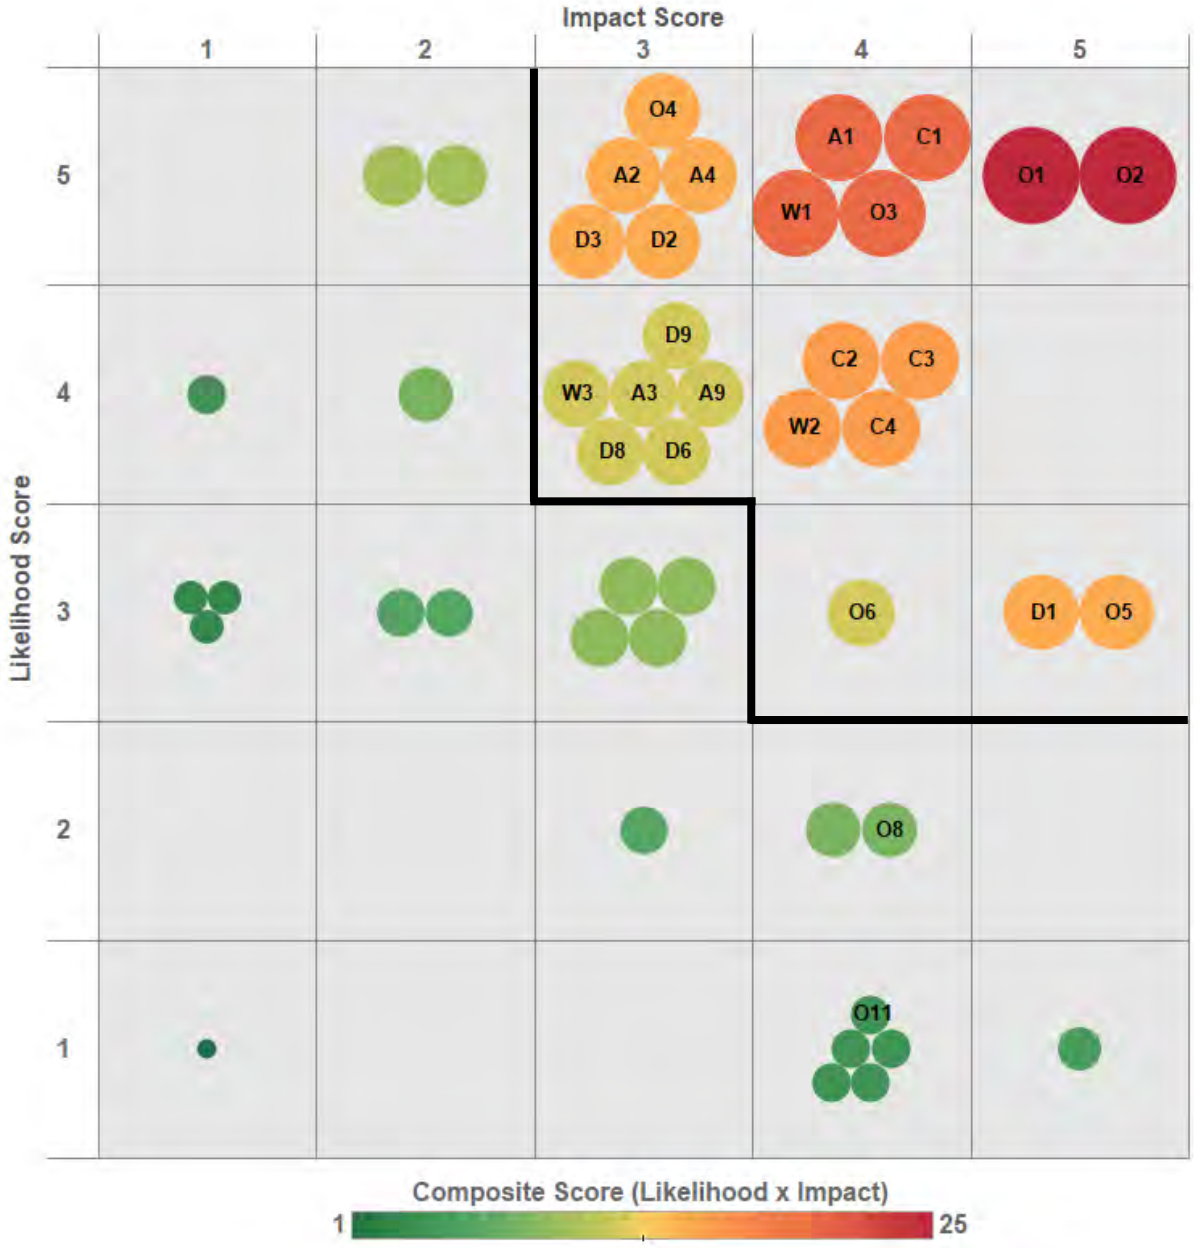
As part of the future planning framework development, the key identified risks and uncertainties will be simulated to quantify their potential impact on FCU water supply system. However, not every risk and uncertainty can be, or needs to be simulated. Therefore, the previously identified risks and uncertainties were prioritized, identifying those that would be simulated to quantify impacts.

The first step to prioritize risks was to select all risks with a composite score of 12 or above (out of a possible 25). FCU felt these risks were impactful enough to warrant their further examination and potential simulation. Next, all risks that received an impact score of 4 or 5 where further examined (regardless of their composite score) as these risks could be significantly impactful even if their likelihood of occurring was low. Of these highly impactful risks, an outage of Joe Wright Reservoir (O8) and an outage of the Pleasant Valley Pipeline (O11) were identified for further analysis.

Figure 2.2 highlights prioritized risks and uncertainties. The color and size of the circles correspond to their composite scores, with larger and redder circles as the risks and uncertainties with greater perceived significance to FCU's water supply system. Labeled risks and uncertainties are those that were prioritized for further analysis, with the black line separating the region with composite scores of 12 and above from the region with scores less than 12. Note the two low likelihood/high impact risks selected that fall outside this boundary.



Note: larger and redder circles indicate a higher composite score. Prioritized risk IDs are labeled with the black line separating the composite scores used for prioritizing

Figure 2.2 – Summary of likelihood and impact scores of identified risks and uncertainties.

The prioritized risks and uncertainties identified above were summarized around five major threat groups that span the various categories: climate change, demands, critical outages, enhanced environmental stressors, and shared infrastructure (i.e. risks or uncertainties due to lack of ownership by FCU in infrastructure). **Table 2.6** lists all the key risks and uncertainties prioritized for simulation and their threat group.

Table 2.6 - List of Key Risks and Uncertainties Prioritized for Simulation

ID	Risk or Uncertainty Name	Threat Group	Likelihood Score	Impact Score	Composite Score
O1	Outage - 24 Pipeline	CO	5	5	25
O2	Outage - 27 Pipeline	CO	5	5	25
O3	Algal Blooms	EES	5	4	20
C1	Longer duration droughts	CC	5	4	20
A1	New Regulations	EES	5	4	20
W1	Wildfires	EES	5	4	20
C3	Change in precipitation type - Hydrology	CC	4	4	16
C4	Changes in frequency/ magnitude of precip events - Hydrology	CC	4	4	16
C2	Changes in runoff timing	CC	4	4	16
W2	Forest Health Degradation	EES	4	4	16
A4	Changing state administration	CC	5	3	15
D3	Development Uncertainty	D	5	3	15
A2	Increased Basin Demands	D	5	3	15
O5	Outage - Horsetooth Reservoir Intake	CO	3	5	15
O4	Outage - Michigan Ditch	CO	5	3	15
D2	Water Use Changes	D	5	3	15
D1	Service area growth and Regionalization	D	3	5	15
A9	Elimination or Interruption of Reuse Plan	SI	4	3	12
D8	Change in precipitation type - Demands	CC	4	3	12
D9	Changes in frequency/ magnitude of precip events - Demands	CC	4	3	12
A3	Changes to Northern Water CBT Operations	SI	4	3	12
W3	Development in Watersheds	EES	4	3	12
D6	Hotter summer changes irrigation	D	4	3	12
O6	Outage - Chambers Reservoir	CO	3	4	12
O8	Outage - Joe Wright Reservoir	CO	2	4	8
O11	Outage - Pleasant Valley Pipeline	CO	1	4	4

Key: CC = Climate Change, CO = Critical Outages, D = Demands, EES = Enhanced Environmental Stressors, SI = Shared Infrastructure

Figure 2.3 summarizes these threats, averaging the likelihood and impact scores across the individual risks and uncertainties for each threat group, with the size of circle and number corresponding to the number of risks and uncertainties within the threat group. The threats associated with climate change, demands, and enhanced environmental stressors are perceived as being highly likely with a significant impact. The critical outage threats are perceived as being moderately likely with a severe impact on the system.

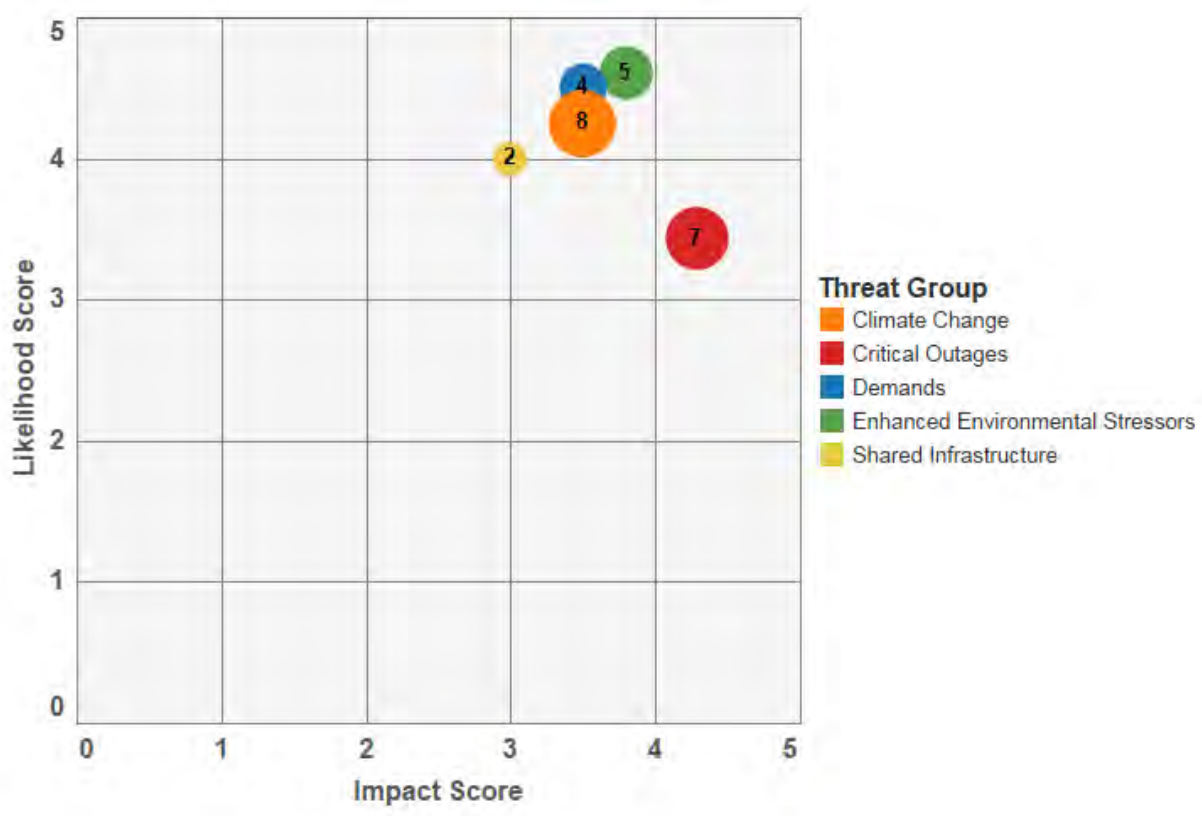


Figure 2.3 – Summary of prioritized risks and uncertainties within each threat group

3.0 C-BT PROJECT WATER SUPPLY SYSTEM RISKS

A significant component of the FCU water supply system is water received from the C-BT Project, owned and operated by Reclamation and Northern. Therefore, as part of the Water Vulnerability Study, risks and uncertainties to the C-BT system were identified by Northern.

Risks and uncertainties to the C-BT Project were identified by staff members from Northern during a half-day workshop. Staff from Northern represented at the workshop included experts in water supply, watershed management, water quality, and operations. FCU staff also participated in the workshop. While the primary goal was to generate risks around the C-BT system that would impact FCU, Northern generated risks across their entire C-BT collection and storage system. These same staff members then scored the identified risks using the rubric described in Section 1.0 based on their perceptions and professional judgment. Therefore, scoring is presented as a *perceived* threat to the water supply system; the actual impact to the water supply system will be quantified for selected key risks using the FCU water resources simulation models.

The scope of the Northern risk and uncertainty evaluation included the C-BT source watersheds, collection system, and storage reservoirs. Risks to the delivery and distribution system were only considered insofar as they could affect deliveries to FCU. As with the Fort Collins risk assessment process, the planning horizon was 50 years.

This section summarizes all risks and uncertainties identified in the Northern workshop and then describes how these identified risks and uncertainties were prioritized for simulation.

3.1 SUMMARY OF ALL RISKS

Identified risks and uncertainties are summarized around five categories that represent different aspects of a water supply system: Climate and Hydrology, Watershed, Operations and Infrastructure, Legal and Administrative, and Demand.

3.1.1 Climate and Hydrology Risks

Table 3.1 lists the six risks and uncertainties associated with the climate and hydrology in the watersheds contributing to the FCU water supply system. For purposes of this evaluation, climate change assumptions in the C-BT source areas were based on general findings of past climate change studies for Colorado and the Front Range region. These studies suggest future climate will be characterized by increased temperature, however the impact on precipitation is unclear as it may increase or decrease.

- CN1 - Longer duration droughts due to increased climate variability or climate change were perceived as a significant threat to the C-BT Project. With respect to the C-BT Project supply, during the first few years of a drought, quota allocations would be set high since allottees use C-BT as a supplemental water supply. If a drought persisted longer than about three years, the C-BT system would become supply-limited and quotas would be set based on the supply available and not the need within the region. It is these types of droughts that last three or more years that would be most impactful to the C-BT system. While not in the observed record, these types of droughts could occur under the current climate, but would also be more frequent and serve under climate change.

- CN2 - An increase in frequency of extremely dry years (e.g., 2002 or 2012) was perceived as a high threat to the C-BT Project. The threat is more pronounced for the Windy Gap system as the C-BT system has sufficient storage to manage through a severe single-year drought. However, if these severe droughts become more frequent, without sufficient recovery, the C-BT system would be impacted.

- CN3 - Reduction in runoff volume due to a warmer, drier climate is perceived as a moderate threat. For example, in 2002 and 2012, warm spring temperatures quickly reduced snowpack without contributing to runoff. With a warmer overall climate projected, those types of spring conditions may be more common. An overall reduction in runoff would eventually translate to less supply available for the C-BT system.

The remaining risks in **Table 3.1** are perceived as less impactful to the C-BT Project water supply system.

Table 3.1 - Identified Northern Water Climate and Hydrology Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
CN1	Longer Duration Droughts	Long-term droughts that have longer durations than occurred in past.	4	5	20
CN2	Increased frequency of extreme dry years	Years like 2002 and 2012 become more frequent	4	4	16
CN3	Changes in runoff volume	Long-term reductions in runoff volume due to hotter, drier climate reduce overall yield	3	4	12
CN4	Changes in runoff timing	Runoff volumes shift earlier in the Spring/Summer with peak runoff occurring earlier. Northern has sufficient storage to capture this and its water rights are not specific in time.	5	2	10
CN5	Increased Evaporation in Reservoirs	Temperature increase results in increased evaporation losses from reservoirs. Overall this would be minimal.	5	2	10
CN6	More precipitation as rain	More precipitation falls as rain instead of snow. The impacts on yields and runoff are uncertain due to complex watershed processes.	5	2	10

3.1.2 Watershed Risks

Table 3.2 lists the nine risks and uncertainties identified that would impact the watershed aspect (i.e. source water areas) of the C-BT Project system.

- WN1 - Changes in wildfire characteristics are perceived as a significant threat to the C-BT system. The likelihood of wildfires in the forested areas that comprise the C-BT watersheds is increasing due to a warmer climate, lack of a recent wildfires, and insufficient forest management in some places. If wildfires were to occur, they could burn longer across a wider area and could also burn hotter, increasing the occurrence of hydrophobic soils. This would amplify many of the negative impacts from wildfires such as decreased water quality, major shifts in the hydrograph, and increased sediment loads. The way in which these secondary impacts affect the C-BT system specifically were considered in separate risks.

- WN2 - A wildfire upstream of Grand Lake and Shadow Mountain Reservoir is perceived as being a highly impactful risk to the C-BT system. Because of the forest characteristics in this area, a fire would result in significant short term and potentially longer term impacts to the operations of Grand Lake and Shadow Mountain Reservoir such as increased sedimentation and decreased water quality. However, these impacts could be mitigated to reduce their impact. The long-term impacts would be changes to the hydrograph and sedimentation issues, which would need to be mitigated after major rainfall events.

- WN3 - Forest health degradation in the C-BT source water watersheds is also perceived as being a highly impactful risk. Factors that could affect forest health were described in Section 2.1.2. The majority of all tributary watersheds to C-BT facilities consist of forested areas managed by federal resource agencies, so Northern is dependent on their forest management programs to maintain the health of its source water areas.

- WN4 - Wildfires on the East Slope of the Continental Divide, specifically in the Big Thompson watershed, are perceived as a moderately impactful risk. Transmountain water is conveyed through a section of the Big Thompson River. If a wildfire in the Big Thompson watershed were to occur, the Big Thompson River may be unable to convey C-BT project water due to water quality issues. However, Northern does have alternative delivery methods that would mitigate the impact of this risk. Additionally, this may impact the ability of allottees to use C-BT Project water due to water quality issues. For example, in the summer and early fall of 2017, there were times when the City of Loveland was unable to utilize its native water rights or C-BT water because of water quality issues in the Big Thompson River as well as an outage on the C-BT system.

- WN5 - Increased sediment loading (resulting from fires, flooding, etc.) in reservoirs and open conveyance systems is perceived as a moderately impactful risk. Shadow Mountain Reservoir is the facility with the most potential to be impacted by sedimentation, especially from a water quality perspective due to its very shallow depth. Other Northern reservoir and conveyance facilities could be more easily managed after major sedimentation events, however there would be short-term operational impacts.

The remaining risks and uncertainties in **Table 3.2** are perceived as being less impactful to the C-BT Project collection water system.

Table 3.2 - Identified C-BT Project Watershed Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
WN1	Changes in wildfire characteristics	Increase in extent and severity of wildfires in high elevation forests degrades water quality, increases sediment loads and changes runoff characteristics	5	4	20
WN2	Wildfires - Upstream of Grand Lake/Shadow Mountain	Increased occurrence of wildfire leads to short term reduced capacity and ability to use Grand Lake/Shadow Mountain Reservoir. Long term channel and sediment changes.	4	4	16
WN3	Watershed forest health degradation	Poorer forest health leads to increase in wildfire risk, water quality impacts, hydrology impacts and increased sediment load.	5	3	15
WN4	Wildfires - East Slope	Increased occurrence of wildfires in Big Thompson River basin degrades water quality and may prevent ability to use Big Thompson River to move C-BT water. Watershed above Lake Estes has lower wildfire impact risk but higher likelihood.	4	3	12
WN5	Increased sediment loading	Increased sediment loading from several causes reduces reservoir or conveyance capacity and affects water quality.	4	3	12
WN6	Flooding	Major flooding events cause mostly short term impacts during which water cannot be used due to compromised water quality.	5	2	10
WN7	Development in Fraser Valley	Residential development increases water quality risks due to urban runoff, return flows and more septic systems.	4	1	4
WN8	Wildfires - East Slope Reservoirs	Wildfires in East Slope reservoir watersheds (e.g., Horsetooth Reservoir watershed) affects water quality, sediment loading and runoff characteristics for drainage into the reservoirs.	4	1	4
WN9	Development above Lake Granby	Residential development increases water quality risks in Lake Granby and Tri-Lakes system.	3	1	3

3.1.3 Operations and Infrastructure Risks

Table 3.3 lists the 22 risks and uncertainties identified that would impact the operations and infrastructure aspect of the C-BT Project water system.

- ON1 - The Green Mountain Reservoir Replacement Pool is operated for Northern to make releases to the Colorado River system in order to offset out-of-priority diversions by the C-BT collection system. These out-of-priority diversions are important to maximizing the yields and benefits of the C-BT Project. If the size of the Green Mountain Reservoir Replacement Pool is inadequate under future hydrologic conditions because of changing hydrographs and river calls, Northern may not be able to use this replacement pool to divert out-of-priority water as efficiently as it has in the past. This would diminish its ability to mitigate a variety of future risks to its water diversions.

- ON2, ON3, ON4 - Three infrastructure outages are perceived as being moderately impactful to C-BT Project supply system. An outage of Unit Number 3 of the Flatiron Facility would restrict pumping into Carter Lake and limit the ability of Northern to deliver C-BT water to southern allottees. An outage of the Power Arm facility would also prevent moving water into Carter Lake and limit the ability of Northern to deliver C-BT water to southern allottees. Finally, an outage of the Southern Water Supply Project, which could occur due to failures or problems with any of the associated pipelines or canals, would prevent water being delivered to southern allottees. None of these three conditions would impact deliveries of C-BT or Windy Gap water to FCU.

The remaining identified risks or uncertainties in **Table 3.3** are perceived as being less impactful to the C-BT Project water system. Many of these can be easily mitigated if they were to occur or there is sufficient redundancy in the system, diminishing their impact. There are several highly impactful risks that will be evaluated further (see Section 3.2), however Northern has a robust asset management and maintenance program that makes the likelihood of these risks very low.

Table 3.3 - Identified C-BT Project Operations and Maintenance Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
ON1	Green Mountain Replacement Pool Inadequacy	With changing hydrology, the 52,000 acre-ft replacement pool may be inadequate to mitigate against a variety of future risks This could reduce Northern's ability to divert out-of-priority water.	4	4	16
ON2	Unit No3 of Flatiron Facility Outage	Failure of Unit 3 in the Flatiron Pump Station prevents pumping water into Carter Lake	4	3	12
ON3	Power Arm Outage	Failure of Power Arm prevents moving water into Carter Lake	4	3	12
ON4	Southern Water Supply Project Outage	Failure of Southern Water Supply Project prevents delivering water to southern allottees	3	4	12
ON5	EPA Transfer Rule	New EPA policy on transbasin diversions makes all existing and future C-BT/Windy Gap subject to discharge requirements	2	5	10
ON6	East Slope Water Rights Uncertainty	Runoff timing changes or increased basin demands impact Northern's yields from East Slope rights and change operation of reservoirs.	3	3	9
ON7	Power Transmission Lines Outages	Wildfire or other emergency causes outage in transmission lines providing power to C-BT/Windy Gap pump stations.	3	3	9
ON8	Algal Blooms	Increased nutrients and temperatures cause algal blooms in reservoirs, impacting suitability of water supply for potable uses	4	2	8
ON9	Aquatic Plants	Increased nutrients and invasive plants grow in reservoirs and canals, impacting operations and potentially increasing treatment requirements	4	2	8
ON10	Invasive Species - Mussels	Mussels clog inlet/outlet pipelines which combined with lack of redundancy may cause short term outages.	2	4	8
ON11	Grand Lake Clarity	Managing to meet clarity requirements leads to less operational flexibility in the system.	4	2	8
ON12	Conveyance Systems to Horsetooth Outage	Variety of events could cause outages or reduced in deliveries in conveyance system components to Horsetooth Reservoir	2	4	8

City of Fort Collins Utilities
Water Vulnerability Study

May 8th, 2018
Water Supply System Risk Identification

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
ON13	Power Generation vs. Water Delivery Operations	Power generation may be given preference over delivering water in C-BT operations	2	4	8
ON14	Grand River Ditch Breach	Failure of the ditch brings sediment into Shadow Mountain/Grand Lake that causes operational changes.	2	3	6
ON15	Conveyance Systems from Carter Lake Outage	Variety of events could cause outages or reduced deliveries from Carter Lake	2	3	6
ON16	Boulder Reservoir Shared Operations	Increased constraints due to Boulder operations impacts ability to deliver water to southern allottees.	2	3	6
ON17	Farr Pump Plant Outage	Pump station failure prevents moving water from Lake Granby to Grand Lake and Adams Tunnel.	1	5	5
ON18	Adams Tunnel Outage	Tunnel failure prevents moving all C-BT/Windy Gap water to East Slope.	1	5	5
ON19	Lake Granby Dam/Dike System Outage	Reduced capacity due to safety reduction or other outage issue limits ability to move water to Grand Lake and Adams Tunnel	1	5	5
ON20	Windy Gap Plant Outage	Pump station failure prevents transfer of Windy Gap water into the C-BT delivery system	1	4	4
ON21	Power Arm and Dille Tunnel Failure (Concurrent)	Concurrent failure of both conveyance facilities would prevent delivering water to Horsetooth Reservoir.	1	4	4
ON22	Willow Creek Pump Plant Outage	Pump station failure prevents pumping C-BT water into Lake Granby and reduces system yield	1	3	3

3.1.4 Legal and Administrative Risks

Table 3.4 lists the four risks and uncertainties identified that would impact the legal and administrative aspect of the C-BT Project water system.

- AN1 - New environmental regulations or changes to existing regulations are perceived as being a moderate threat to the C-BT Project water system. These could result in additional water being required for environmental purposes, which could reduce the C-BT yield and hence the quota set for allottees. Additionally, new infrastructure or improvements to existing infrastructure would be more difficult to permit if new species were added to federal and state lists of protected species or mitigation requirements were expanded.

- AN2 - Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project. Colorado River flows for 2000-2017 represent a significant drought event when compared to both relatively recent recorded data and flow records reconstructed from tree-ring records that go back over one thousand years. The 10 year rolling average of actual flows in the Colorado River below Lake Powell is currently approximately 91 million acre feet. It is not possible to predict if or when actual flows in the Colorado River below Lake Powell will fall below 75 million acre feet on a 10 year rolling average, how long actual flows in the Colorado River below Lake Powell could be below 75 million acre feet on a 10 year rolling average, or whether and how such flows would, under the Colorado River Compact or Upper Colorado River Compact, affect Colorado-Big Thompson Project diversions. Given these uncertainties, the modeled scenarios include a scenario with no diversions by the C-BT Project and a scenario with an extended period of reduced diversions by the C-BT Project, which is represented in the Green Mountain Pool scenario. These scenarios are intended to assess the impact of outages or reduced diversions caused by reduced flows in the Colorado River that are not dependent on currently unknown future hydrology or legal requirements.

The remaining risks and uncertainties in **Table 3.4** are perceived as being less impactful than those described above.

Table 3.4 - Identified C-BT Project Legal and Administrative Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
AN1	Environmental Regulations (changes, new, compliance)	New regulations or changes in federal permitting compliance may lead to more water used for environmental mitigation/flows.	3	4	12
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project	Possible changes in C-BT operations based on hydrologic uncertainties and a large C-BT Project outage.	2	5	10
AN3	Windy Gap renegotiation	When current 40-year contract limit expires, a renegotiated contract gives less yield (due to increased shrink for example)	5	2	10
AN4	Federal law requires modification of Project Operations.	Federal law requires changes in how the C-BT Project is operated (e.g. for endangered species), reducing C-BT/Windy Gap yield	2	4	8

3.1.5 Demand Risks

Table 3.5 lists the five risks and uncertainties identified that would impact demand aspect of the C-BT Project water system.

Northern is a raw water supplier with a fixed amount of supply available to allocate each year. In that sense its operations are not directly driven by changes in the demands of its allottees. While allottee demands may indirectly impact Northern, the district has a fixed number of units and its quota system allows it to control the amount of water distributed annually to its allottees. Therefore, none of the demand risks or uncertainties are perceived as being significantly impactful to the C-BT Project water system.

Table 3.5 - Identified Northern Water Demand Risks and Uncertainties

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score
DN1	Longer Growing Season	Hotter, drier climate lengthens the growing season for agricultural and M&I allottees, increasing their demands and changing when they need C-BT/Windy Gap water	5	2	10
DN2	Changes in C-BT Users	Continued shift in C-BT ownership to M&I users, who would want quotas set differently than agricultural users.	5	1	5
DN3	Uncertainty of Setting Quota	Change in ownership and Board membership changes the process by which quota is set. May be narrower range to satisfy M&I allottees.	3	1	3
DN4	Increase in quota use	Quotas are not set as high, but as time goes on actual water use is closer to the quota amount.	4	1	4
DN5	Northern Water Management Program Changes	Changes to the Annual Carryover Storage program or Regional Pool program occur, making water management for M&I allottees less flexible.	3	1	3

3.2 PRIORITIZED RISKS

Figure 3.1 plots all risks and uncertainties identified by Northern as a circle on a grid corresponding to their likelihood and impact scores, with the impact score as columns and the likelihood score as rows. The color of the circle corresponds to the category the risk or uncertainty originates from and the label is the ID of the risk or uncertainty. In total, 45 risks and uncertainties were identified by Northern.

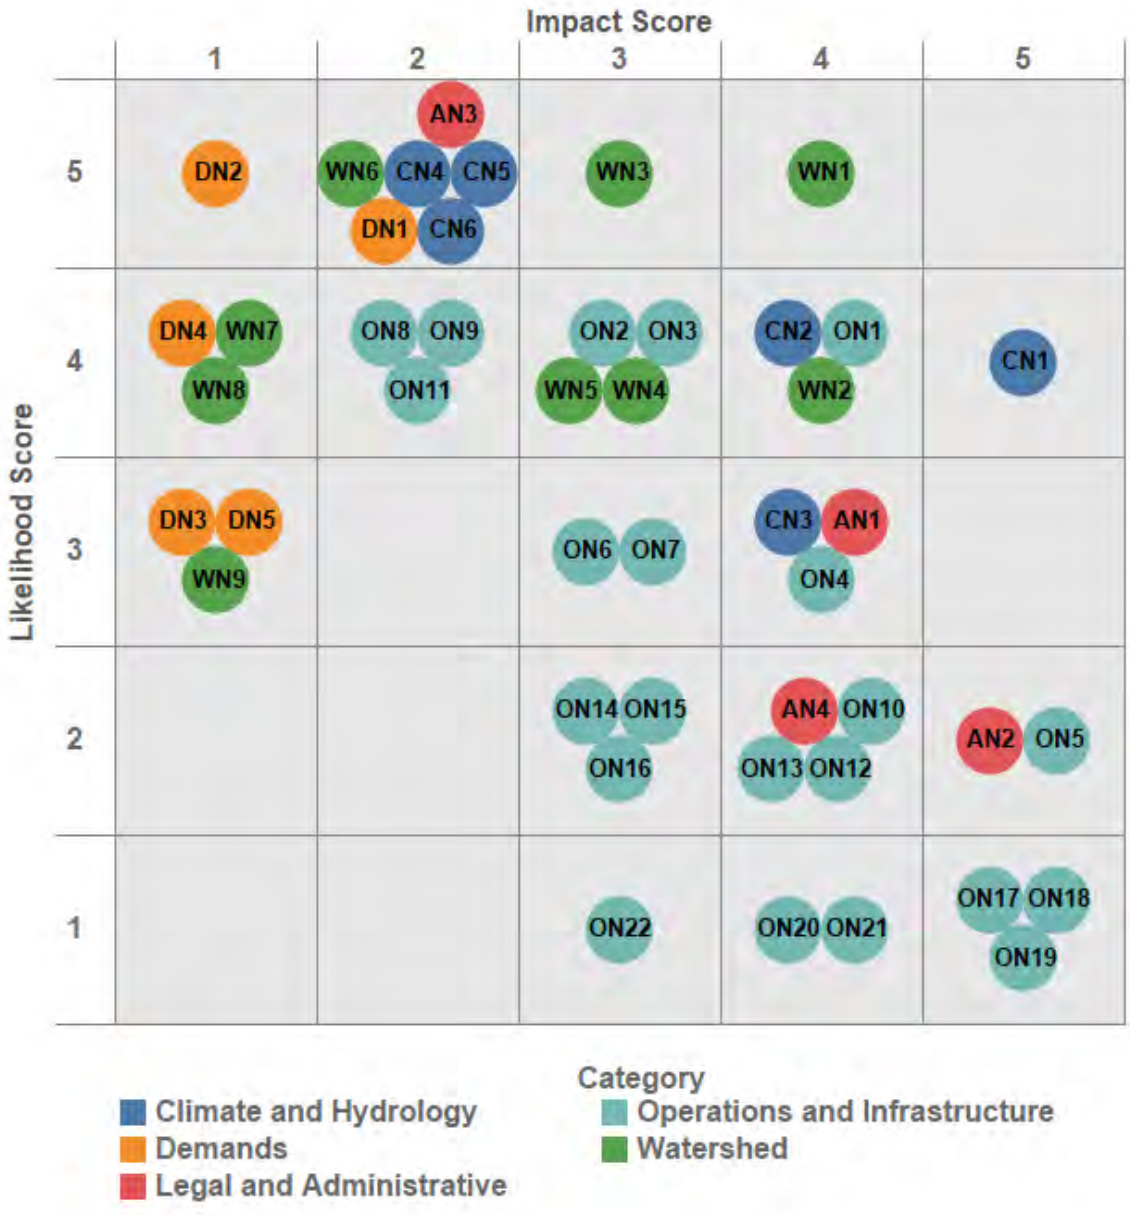

Figure 3.1 - Risks and uncertainties identified by Northern.

As part of the larger FCU Water Vulnerability Study, the risks and uncertainties identified by Northern need to be translated to C-BT quota impacts because C-BT deliveries comprise a significant portion of FCU water supply. The annual C-BT yield based on the quota is an important input to the FCU water resources model. The process used by the Northern Board to set the annual C-BT quota is based on a number of factors including supplemental regional need, hydrology, amount of water in storage, and past Board experience. Northern has a model that estimates a C-BT quota depending on West Slope and East Slope hydrology and operations of their major reservoirs. This model will be used to estimate the effect of risks and uncertainties on the C-BT quota. However, not every risk and uncertainty needs to be simulated. Therefore, the previously identified risks and uncertainties were prioritized, identifying those that would be simulated in the C-BT quota model.

Similar to the process used by FCU, the first step to prioritize risks was to include all risks with a composite score of 12 or above (out of a possible 25). Northern and FCU felt these risks were impactful enough to warrant further examination and potential simulation. Additionally, all risks that received an impact score of 4 or 5 were further examined (regardless of their composite score) as these risks could be significantly impactful even if their likelihood of occurring was low. Of these highly impactful risks, those prioritized were:

- Conveyance system to Horsetooth Reservoir Outage (ON12)
- Adams Tunnel Outage (ON18)
- Farr Pump Plant Outage (ON17)
- Lake Granby Dam/Dike System Outage (ON19)
- Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project (AN2)
- Windy Gap Plant Outage (ON20)

Note: larger and redder circles indicate a higher composite score. Prioritized risk IDs are labeled with the black line separating the composite scores used for prioritizing

Figure 3.2 plots all identified risks and uncertainties as a circle on a grid corresponding to their likelihood and impact scores, with the impact score as columns and the likelihood score as rows. The color and size of the circles correspond to their composite scores, with larger and redder circles indicating the risks and uncertainties perceived as being more impactful to the C-BT Project water system. Labeled risks and uncertainties are those that were prioritized for further analysis, with the black line separating the region with composite scores of 12 and above from the region with scores less than 12.

Note: larger and redder circles indicate a higher composite score. Prioritized risk IDs are labeled with the black line separating the composite scores used for prioritizing

Figure 3.2 - Summary of likelihood and impact scores of Northern Water identified risks and uncertainties.

The prioritized risks and uncertainties identified above were then summarized around the same five major threat groups used by FCU: climate change, demands, critical outages, enhanced environmental stressors, and shared infrastructure. **Table 3.6** lists the key risks and uncertainties prioritized for simulation and their threat group.

Table 3.6 - List of Northern Water Prioritized Risks and Uncertainties

ID	Name	Threat Group	Likelihood Score	Impact Score	Composite Score
CN1	Longer Duration Droughts	CC	4	5	20
WN1	Changes in wildfire characteristics	EES	5	4	20
CN2	Increased frequency of extreme dry years	CC	4	4	16
ON1	Green Mountain Replacement Pool Inadequacy	D	4	4	16
WN2	Wildfires - Upstream of Grand Lake/Shadow Mountain	EES	4	4	16
WN3	Watershed forest health degradation	EES	5	3	15
AN1	Environmental Regulations (changes, new, compliance)	EES	3	4	12
CN3	Changes in runoff volume	CC	3	4	12
ON3	Power Arm Outage	CO	4	3	12
ON4	Southern Water Supply Project Outage	CO	3	4	12
ON2	Unit No3 of Flatiron Facility Outage	CO	4	3	12
WN5	Increased sediment loading	EES	4	3	12
WN4	Wildfires - East Slope	EES	4	3	12
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project	CC/CO	2	5	10
ON12	Conveyance Systems to Horsetooth Outage	CO	2	4	8
ON18	Adams Tunnel Outage	CO	1	5	5
ON17	Farr Pump Plant Outage	CO	1	5	5
ON19	Lake Granby Dam/Dike System Outage	CO	1	5	5
ON20	Windy Gap Plant Outage	CO	1	4	4

Key: CC = Climate Change, CO = Critical Outages, D = Demands, EES = Enhanced Environmental Stressors, SI = Shared Infrastructure

Figure 3.3 summarizes these threats, averaging the likelihood and impact scores across the individual risks and uncertainties for each threat, with the size of circle and number corresponding to the number of risks and uncertainties within the threat group. Shared infrastructure risks were not identified as threats. Critical outages are perceived to be unlikely to occur, but are significantly impactful if they do. Climate change is perceived as being both likely to occur and significantly impactful.

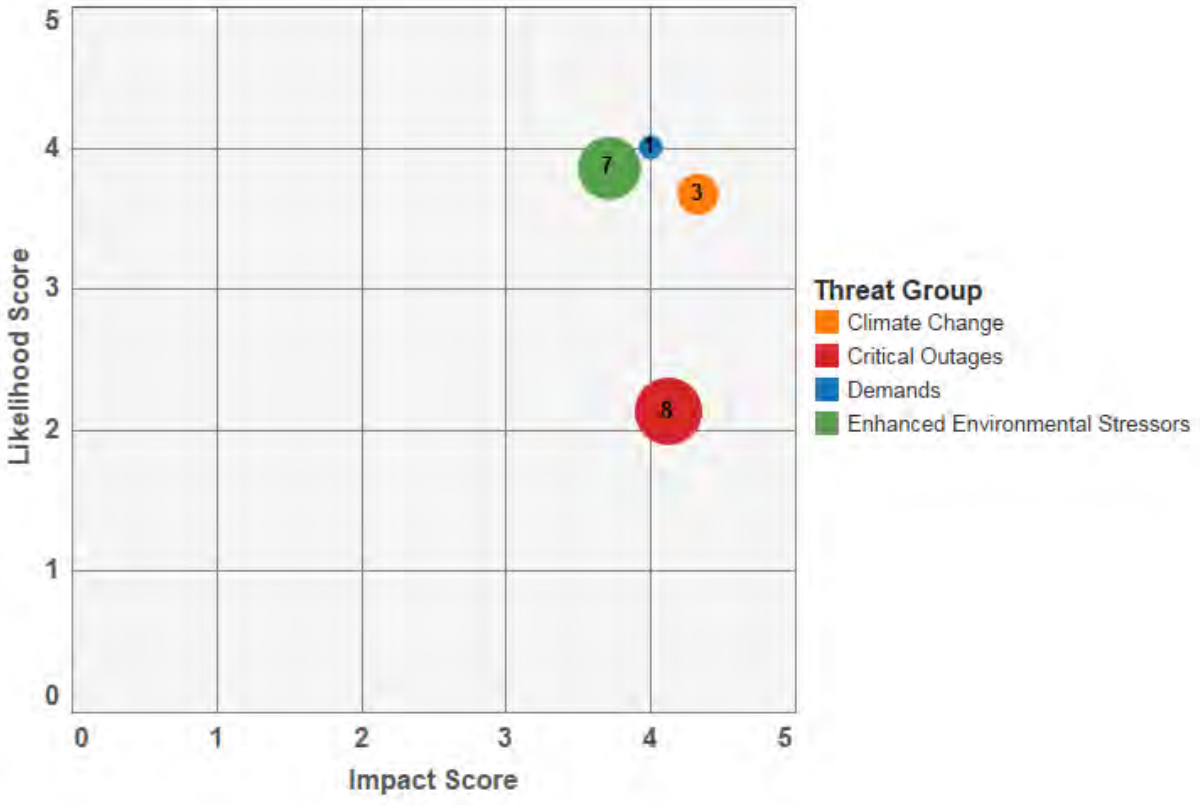

Figure 3.3 - Summary of Northern Water prioritized risks and uncertainties within each threat group

4.0 SIMULATION APPROACH FOR SELECTED RISKS

To develop the future planning framework for the Fort Collins Water Vulnerability Study, the impacts of the identified risks and uncertainties on the water supply system need to be quantified. The Fort Collins and Northern water resources models will be used to simulate these impacts, providing objective information about which risks and uncertainties are a significant threat.

Therefore, a simulation approach for the prioritized risks and uncertainties identified by FCU for its water supply system in Section 2 and the prioritized risks and uncertainties identified by Northern for the C-BT Project in Section 3 was developed. This approach is described in this section.

4.1 GENERAL SIMULATION APPROACH

The risk and uncertainty simulation process requires a reasonable estimate of the water supply feature being impacted by each key risk/uncertainty, the duration of the impact, and determination of the models that should be used to simulate its effects. Some risks or uncertainties, though prioritized, will not be explicitly simulated in the models though their specific impacts will be qualitatively described.

There are three models that represent FCU's water supply system, described below. How the simulation approach will be specifically applied to each model is described in more detail in Section 4.2, Section 4.3, and Section 4.4. Risks related to the Reuse Plan are not finalized at this time but will be added to the documentation when they are.

- The Fort Collins System Model (FCM) simulates the operation of infrastructure used to deliver yields from sources to FCU's water treatment plant.
- The Poudre Basin Network (PBN) model simulates the water allocation and storage for water users in the Poudre River basin.
- The C-BT Quota model (CBTQ) simulates the anticipated quota for C-BT allottees based on hydrology, operations of the major reservoirs in the C-BT system, and other factors.

Table 4.1 presents the proposed simulation approach for the prioritized risks and uncertainties related to the FCU water supply system described in Section 2.2. For risks with a simulation approach that is applied for a fixed period of time (e.g., June-October, 5 years), the simulated year that risk occurs will be fixed (e.g. year 10 of the simulation) across all three models. Because different hydrology are being developed for these models, risks occurring the same simulated year will occur across a variety of hydrologic conditions (e.g. short droughts, multi-year droughts, wet periods, drought recovery).

Table 4.1 – Simulation approach for FCU water supply system risks and uncertainties

ID	Risk or Uncertainty Name	Model for Simulation	Simulation Approach
O1	Outage – 24" Pipeline	FCM	100% outage between October and March, when impact would be most severe to operations. Will be combined with 27" Pipeline Outage in model.
O2	Outage – 27" Pipeline	FCM	100% outage between October and March, when impact would be most severe to operations. Will be combined with 24" Pipeline Outage in model.
O3	Algal Blooms	FCM	C-BT water use will be reduced by a fixed percent between June-October.
C1	Longer duration droughts	All	Incorporated into new stochastic hydrology
A1	New Regulations- Water quality and environmental	Not Simulated	
W1	Wildfires	FCM	Outage of non-C-BT supply between June-September, followed by 10-year, 20% reduction in non C-BT-supply.
C3	Change in precipitation type - Hydrology	All	Incorporated into new stochastic hydrology
C4	Changes in frequency/magnitude of precipitation events - Hydrology	All	Incorporated into new stochastic hydrology
C2	Changes in runoff timing	All	Incorporated into new stochastic hydrology
W2	Forest Health Degradation	Not Simulated	
A4	Changing state water rights administration	Not Simulated	
D3	Development Uncertainty	FCM/PBN	Captured in demand scenario modeling
A2	Increased Basin Demands	Not Simulated	A separate sensitivity analysis around this was completed by FCU and found no significant impact on water availability.
O5	Outage - Horsetooth Reservoir Outlet	FCM	Horsetooth empties in October, then 100% storage capacity reduction for 9 months, though water can still flow through the reservoir.
O4	Outage - Michigan Ditch	FCM	100% reduction for 24 months
D2	Water Use Changes	FCM	Captured in demand scenario modeling

ID	Risk or Uncertainty Name	Model for Simulation	Simulation Approach
D1	Service area growth and regionalization	FCM	Apply a percent increase to demands in new demand model based on how much demands may increase.
D8	Change in precipitation type - Demands	FCM	Captured in demand scenario modeling
D9	Changes in frequency/magnitude of precipitation events - Demands	FCM	Captured in demand scenario modeling
A3	Changes to Northern Water C-BT Operations	FCM/PBN	Simulate various quota assumption scenarios (e.g. fixed 50% quota). Scenarios to be developed.
W3	Development in Watersheds	Not Simulated	
D6	Hotter summer changes irrigation	FCM	Captured in demand scenario modeling
O6	Outage - Chambers Reservoir	Not Simulated	
O8	Outage - Joe Wright Reservoir	FCM	100% reduction in capacity for 24 months starting in November. All inflows bypassed.
O11	Outage - Pleasant Valley Pipeline	FCM	100% reduction from April-October
A9	Elimination or Interruption of Reuse Plan	FCM	In development

Table 4.2 presents the simulation approach for the prioritized risks and uncertainties related to the C-BT water supply system described in Section 3.2.

Table 4.2 - Simulation approach for the C-BT Project water system risks and uncertainties

ID	Name	Model for Simulation	Simulation Approach
CN1	Longer Duration Droughts	CBTQ	Incorporated into new hydrology.
WN1	Changes in wildfire characteristics	Not Simulated	
CN2	Increased frequency of extreme dry years	CBTQ	Incorporated into new stochastic hydrology.
ON1	Green Mountain Replacement Pool Inadequacy	CBTQ	Reduce inflows into model to account for loss of out-of-priority diversions.
WN2	Wildfires - Upstream of Grand Lake/Shadow Mountain	Not simulated	Potential quota changes captured in other risks.
WN3	Watershed forest health degradation	Not simulated	
AN1	Environmental Regulations (changes, new, compliance)	CBTQ	Reduce inflows into model to account for loss due to increased environmental flows.
CN3	Changes in runoff volume	CBTQ	Incorporated into new stochastic hydrology.
ON3	Power Arm Outage	Not simulated	Doesn't impact quota setting or deliveries of C-BT supply to FCU
ON4	Southern Water Supply Project Outage	Not simulated	Doesn't impact quota setting or deliveries of C-BT supply to FCU

ON2	Unit No3 of Flatiron Facility Outage	Not simulated	Doesn't impact quota setting or deliveries of C-BT supply to FCU
WN5	Increased sediment loading	Not Simulated	Shadow Mountain Reservoir is mostly a pass through reservoir, so may not be greatly affected by reduced capacity.
WN4	Wildfires - East Slope	CBTQ	Reduction in Big Thompson-captured inflows. No delivery of C-BT water to certain water users (e.g. Greeley) through Big Thompson River.
ON12	Conveyance Systems to Horsetooth Outage	FCM	Doesn't impact quota setting. 100% reduction in C-BT delivery to Horsetooth Reservoir from January – June. Existing water in Horsetooth Reservoir still useable.
ON18	Adams Tunnel Outage	FCM/PBN	100% reduction in West Slope yields for a single year. Anticipated quota scenario will be developed.
ON17	Farr Pump Plant Outage	FCM/PBN	60% reduction in West Slope yields for a single year. Anticipated quota scenario will be developed.
ON19	Lake Granby Dam/Dike System Outage	FCM/PBN	100% reduction in West Slope yields for a single year. Anticipated quota scenario will be developed.
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project	CBTQ	A reactive response that is a 100% reduction in West Slope inflows for 5 years.
ON20	Windy Gap Plant Outage	CBTQ	100% reduction in West Slope yields for a single year.

4.2 FORT COLLINS SYSTEM MODEL

Many of the risks presented in Table 4.1 will be simulated by adjusting specific links and/or nodes in the FCM model. Others will be captured by altering the demand inputs or the hydrology inputs to the model.

Table 4.4 details how the risk will be initiated, how long the risk will last and which nodes or links will be adjusted in the FCM model to simulate the modeled risks. Table 4.5 lists the risks that are not modeled by adjusting a link or node setting, but rather by altering the demand inputs or hydrology inputs to the FCM model.

Table 4.3- Simulation method for risks and uncertainties affecting the Fort Collins System Model

ID	Risk or Uncertainty Name	Risk Initiation	Reduction Factor	Duration (timesteps)	FCM Nodes/Links
O1	Outage – 24" Pipeline	Random, starting in October	100	12	Pipecap link will be split into three links (multilink). Only one of the three links will be affected.
O2	Outage – 27" Pipeline	Random, starting in October	100	12	Pipecap link will be split into three links (multilink). Only one of the three links will be affected.
O3	Algal Blooms	Annual Canyon Mountain Naturalized Flow. Bin into three bins based off current hydrology. Select a random year from within the dry bin.	Blending construct	5	Simulated in new blending construct
W1	Wildfires	Hydrology-based	Year 1: 100% Years 2-10: 25%	Year 1: June-September Years 2-10: April-October	Pipecap link will be split into three links (multilink). Which link or links will be affected?
O5	Outage - Horsetooth Reservoir Outlet	Random, starting in October	100	9	Horsetooth_StoRight node target and capacity
O4	Outage - Michigan Ditch	Random, starting in June	100	24	MD link
O8	Outage - Joe Wright Reservoir	Random, starting in November	100	24	JoeWright_StoRight node
O11	Outage - Pleasant Valley Pipeline	Random, starting in April	100	12	Pipecap link will be split into three links (multilink). Which link or links will be affected?
A9	Reuse Plan Gone				Developed as part of Reuse Plan simulation
A9	Reuse Plan Interrupted				Developed as part of Reuse Plan simulation
ON12	Conveyance Systems to Horsetooth Outage	Random, starting in April	100	January-June	cbtin link

Table 4.4- Summary of risks and uncertainties reflected in demand or hydrology inputs to the Fort Collins System Model

ID	Risk or Uncertainty Name	Simulation Approach
C1	Longer duration droughts	Incorporated into new stochastic hydrology
C2	Changes in runoff timing	Incorporated into new stochastic hydrology
C3	Change in precipitation type - Hydrology	Incorporated into new stochastic hydrology
C4	Changes in frequency/magnitude of precipitation events - Hydrology	Incorporated into new stochastic hydrology
D1	Service area growth and regionalization	Apply a percent increase to demands in new demand model based on how much demands may increase.
D2	Water Use Changes	Captured in demand scenario modeling
D3	Development Uncertainty	Captured in demand scenario modeling
D6	Hotter summer changes irrigation	Captured in demand scenario modeling
D8	Change in precipitation type - Demands	Captured in demand scenario modeling
D9	Changes in frequency/magnitude of precipitation events - Demands	Captured in demand scenario modeling

4.3 POUDRE BASIN NETWORK MODEL

PBN model output serves as hydrology input to the FCM model, so only hydrology-based risks will be simulated in the PBN model. By altering PBN inputs based on the risks, the PBN output will reflect the simulated risks, which will be used as input to the FCM model. Table 4.6 lists the risks that are simulated in the PBN model.

Table 4.5- Summary of risks and uncertainties reflected in hydrology inputs to the PBN Model

ID	Risk or Uncertainty Name	Simulation Approach
C1	Longer duration droughts	Incorporated into new stochastic hydrology
C2	Changes in runoff timing	Incorporated into new stochastic hydrology
C3	Change in precipitation type - Hydrology	Incorporated into new stochastic hydrology
C4	Changes in frequency/magnitude of precipitation events - Hydrology	Incorporated into new stochastic hydrology

4.4 NORTHERN WATER QUOTA MODEL

The CBTQ model output will be used as input to both the PBN model and the FCM model. The risks identified by Northern in Table 4.2 will alter how the quota is set; and thus, will need be simulated in the CBTQ model. The quotas produced will be used as inputs to the PBN and FCM models, and will reflect the simulated risk.

Table 4.7 details how specific model objects in the CBTQ model are adjusted to simulate the identified risks. Table 4.8 lists the risks that are modeled by altering the hydrologic inputs to the CBTQ model.

Table 4.6- Simulation method for risks and uncertainties affecting the CBTQ Model

ID	Risk or Uncertainty Name	Duration	CBTQ Model Objects	Model Object Setting
WN4	Wildfires - East Slope	3 years	Timeseries Sheet: column “East Slope Wildfires”	1 in year of the fire and following 2 years
			Model Control Sheet: Cell B49	100
ON20	Windy Gap Plant Outage	1 year	Timeseries Sheet: column “Windy Gap Pump Outage”	1 in year(s) of pump outage

Because of the operation of the C-BT Project by which allottees are delivered water via a quota that is set each year, risks and uncertainties interact with the C-BT and FCU water supply systems differently. Some risks and uncertainties impact how the quota is set while others impact how the water committed under the quota is delivered. The CBTQ model captures how risks and uncertainties to hydrology and reservoirs would impact how the quota is set. However risks and uncertainties that impact how the water committed under the quota is delivered are not captured in the CBTQ model. Therefore for the Water Vulnerability Study, quota scenarios, in addition to those simulated in the CBTQ model, will be developed for risks and uncertainties that are not captured in the CBTQ model and applied to the PBN and FCM models. **Table 4.3** summarizes the quota scenarios developed and the risks and uncertainties they capture.

Table 4.7 - Quota Scenarios for the FCM and PBN Models

Scenario Name	Description	Risks and Uncertainties Captured
Adams Tunnel Outage	Quota is set to 25% in the three years following the outage for all Horsetooth storage levels.	Adams Tunnel Outage (ON18)
Farr Pump Plant Outage	Quota is set to 39% in the three years following the outage for all Horsetooth storage levels.	Farr Pump Plant Outage (ON17)
Lake Granby Dam/Dike System	Quota is set to 40% in the three years following the outage for all Horsetooth storage levels.	Lake Granby Dam/Dike System Outage (ON9)

Table 4.8- Summary of risks and uncertainties reflected in hydrology inputs to the CBTQ Model

ID	Risk or Uncertainty Name	Simulation Approach
CN1	Longer Duration Droughts	Incorporated into new hydrology.
CN2	Increased frequency of extreme dry years	Incorporated into new stochastic hydrology.
CN3	Changes in runoff volume	Incorporated into new stochastic hydrology.
ON1	Green Mountain Replacement Pool Inadequacy	Incorporated into new hydrology
AN1	Environmental Regulations (changes, new, compliance)	Incorporated into new hydrology
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project- Reactive Response	Incorporated into new hydrology

5.0 SUMMARY AND CONCLUSIONS

As part of the Fort Collins Water Vulnerability Study, a future planning framework to evaluate the need for new water supply strategies is being developed. A key part of this framework will be incorporating risks and uncertainties that could negatively impact FCU's ability to deliver water to its customers. Therefore, risks and uncertainties to the FCU water supply system were identified and prioritized. Because FCU gets a significant portion of its supply from the C-BT Project, risks and uncertainties to the C-BT project were also identified by Northern.

In total, 46 risks and uncertainties were identified for the FCU water supply system and 53 risks and uncertainties were identified for the C-BT system. Each of these were assigned a likelihood score and an impact score by staff from each agency based on their professional judgment. These risks and uncertainties were then prioritized for simulation using the composite score (likelihood score x risk score). 25 risks and uncertainties related to the FCU water supply system were prioritized for simulation and 24 risks and uncertainties related to the C-BT system were prioritized for simulation.

For each of these key prioritized risks and uncertainties, a simulation approach was developed to capture their potential impact in one of models used to simulate the FCU water supply system and the C-BT annual quota. These individual risks and uncertainties will then be combined into various scenarios and simulated in the water resources models, using performance metrics and level of service goals to determine which risks and uncertainties should be included in the future planning framework.

APPENDIX A – FORT COLLINS UTILITIES RISK AND UNCERTAINTY TABLES

A.1 Climate and Hydrology

The following table presents the climate and hydrology risks and uncertainties identified by FCU and their associated scores and additional notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
C1	Longer duration droughts	Multi-year and/or more severe droughts occur in the future that are not captured in the observed record.	5	4	20	Could be caused by natural climate variability or climate change. Longer periods of low streamflow and reduced yields from water rights.
C2	Changes in runoff timing	Early higher runoff and lower late-season baseflow reduces yield from volumetric decrees that list specific diversion dates.	4	4	16	Earlier runoff is already occurring compared to historical averages. Fort Collins system is vulnerable due to limited storage. Water rights have highly specific timing of decreed water which may reduce yields if there is changes in runoff timing.
C3	Change in precipitation type	More precipitation falls as rain instead of snow during the Fall and Spring.	4	4	16	This is occurring now relative to historical averages. Reduces benefits of "snowpack reservoir." Fort Collins system is vulnerable due to limited storage.
C4	Changes in frequency/ magnitude of precipitation events	Precipitation events, particularly summer rainstorms, become less frequent and more intense.	4	4	16	More intense storms could cause flooding, damaging infrastructure. More storms like September 2013.
C5	Longer growing season	Warmer climate increases growing season in Spring and Fall, changing potential water rights calls and increasing irrigation demand.	4	2	8	Increased agricultural diversions in Spring and Fall could affect yield from Fort Collins rights. However, many ag users already use most of their decreed supply and there is research that shows that longer growing seasons may reduce water-intensive crops.

A.2 Watershed

The following table presents the watershed risks and uncertainties identified by FCU and their associated scores and additional notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
W1	Wildfires	Wildfires occur, causing a variety of impacts on water quality, runoff, and threats to infrastructure.	5	4	20	Climate change leading to hotter, drier climate would increase risk of wildfire. High Park Fire demonstrated wildfire threat. Water quality has short term and long term effects that make Poudre River water untreatable. Wildfire itself and sediment loads from runoff after the fire could affect diversions and conveyance systems in the FCU system.
W2	Forest Health Degradation	Forested area health decreases due to beetle kill, pollution, warming climate, etc.	4	4	16	Declining forest health could affect streamflow magnitude and timing (higher peak, earlier runoff) and degrade water quality. Also, increases risk of wildfire.
W3	Development in Watersheds	Land development in watersheds (recreation, residential, O&G, mining) increases risk of water quality contamination.	4	3	12	Long-term water quality degradation due to increased road traffic and septic systems and increased risk of acute contamination events due to spills or vehicle accidents.
W4	Atmospheric Deposition	Increased levels of contaminants in bodies of water and forests lead to new water quality issues	5	2	10	Deposition of nutrients in pristine high-altitude bodies of water increases risk of algal blooms or other water quality issues that could impact water quality and availability.
W5	Deficiencies in Federal land Management	Federally owned land, which comprises nearly all of the watersheds, is poorly managed against wildfires or to promote forest health	2	3	6	Over 90% of Fort Collins water supply yield is derived from land owned and managed by the Federal government. Challenges with proactive forest management increase frequency and/or severity of wildfires. Limited rehabilitation of forests after a wildfire increase risk to water quality contamination, sedimentation, and runoff timing changes.
W6	Abandoned Mine Runoff	Runoff from abandoned mines leads to decreased water quality in FCU watersheds.	1	4	4	Abandoned mines could release metals and other toxic chemicals. Few mines in the Fort Collins source watersheds so low likelihood of problems.
W7	Privatization of Public Lands	Lands owned by the federal government are transferred to private entities, increasing development potential	1	4	4	More area for development and more development intensity would increase risk of impacts of development as described above.

A.3 Operations and Infrastructure

The following table presents the operations and infrastructure risks and uncertainties identified by FCU and their associated scores and notes

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
O1	Outage - 24 Pipeline	Short term outage due to flooding, landslides, wildfire, etc.	5	5	25	Inability to convey Poudre River supply to WTP without pipeline. High risk of landslides, full alignment uncertain, in river stretches increases risk of filling with sediment if it fails. Sections very difficult to access.
O2	Outage - 27 Pipeline	Short term outage due to flooding, landslides, wildfire, etc.	5	5	25	Inability to convey Poudre River supply to WTP. High risk of landslides, hard to access in event of failure.
O3	Algal Blooms	Algal blooms in storage reservoirs and rivers increases water quality issues and potential treatment problems	5	4	20	Due to variety of factors, increased risk of algal blooms in Fort Collins storage facilities. Current WTP unable to treat water with algal contaminants; could potentially significantly restrict available water in late summer/fall months.
O4	Outage - Michigan Ditch	Short term outage due to flooding, landslides, wildfire, etc.	5	3	15	Inability to convey transmountain supply to WTP. Variety of factors could lead to outage.
O5	Outage - Horsetooth Reservoir Outlet	Short term outage of reservoir outlet and intake to WTP; higher risk due to lack of redundancy	3	5	15	Inability to convey CBT supply from Horsetooth Reservoir to WTP. Outage of the Horsetooth Reservoir intake recently occurred, validating this risk.
O6	Outage - Chambers Reservoir	Short term outage due to flooding, landslides, wildfire, etc.	3	4	12	Maintenance is underfunded, increasing risk of failures. Fort Collins has minimal influence or control over reservoir.
O7	Outage - Munroe Canal	Short term outage due to flooding, landslides, wildfire, etc.	3	3	9	Inability to convey NPIC shares to City WTP.
O8	Outage - Joe Wright Reservoir	Short term outage due to flooding, landslides, wildfire, etc.	2	4	8	Inability to access water from storage in Joe Wright Reservoir. There is currently an active landslide in reservoir footprint. Fort Collins owns minimal land around reservoir, increasing risk due to wildfires and their impacts.
O9	Shared infrastructure - Chambers Reservoir	Lack of control of operations could lead to issues with delivering water	2	4	8	City cannot control movement of its water to its system, so may not have access to supply when needed

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
O10	Outage - Meadow Creek Reservoir	Short term outage due to flooding, landslides, wildfire, etc.	3	2	6	Impact could be significantly higher if outage occurs during drought event as it was Fort Collins sole source of water during 2002 drought.
O11	Outage - Pleasant Valley Pipeline	Short term outage due to flooding, landslides, wildfire, etc.	1	4	4	Inability to use PVP to convey Poudre River supply to WTP. Shared ownership with Northern, low exposure risk.
O12	Shared infrastructure - Munroe Canal	Lack of control of operations could lead to issues with delivering water	1	4	4	City cannot control movement of its water to its system due to NPIC decisions, so may not have access to supply when needed
O13	Shared infrastructure - Pleasant Valley Pipeline	Lack of control of operations could lead to issues with delivering water	1	4	4	City cannot control movement of its water to its system due to the PVP participant decisions (Greeley, TriDistricts), so may not have access to supply when needed.
O14	Sediment Loading - Reservoirs	Loss of capacity in reservoirs due to increased sediment loads	3	1	3	Long term reduction in available storage.
O15	Freeze/Thaw Cycles	Initial freezing stages impact water quality, ice coming down the river could impact operations	3	1	3	More frequent degraded water quality. Potential damage to diversion structures could limit ability to access Poudre River supply.
O16	Shared infrastructure - Meadow Creek Reservoir	Lack of control of operations could lead to issues with delivering water	1	1	1	City cannot control movement of its water to its system due to decisions by others, so may not have access to supply when needed.

A.4 Legal and Administrative

The following table presents the legal and administrative risks and uncertainties identified by FCU and their associated scores and additional notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
A1	New Regulations - Water Quality	New regulations (either federal or state) impact availability of yields from existing water rights	5	4	20	Existing supplies may not meet standards without additional treatment. Could affect ability to blend Poudre water and CBT water.
A2	Increased Basin Demands	Higher demands across the entire Poudre River basin (due to climate change/population growth) impact use of water rights	5	3	15	Could increase annual demands and extend irrigation period. Magnitude of impact is uncertain without modeling of system performance.
A3	Changes to Northern Water CBT Operations	Allocation of CBT water through setting of the quota, and ways in which CBT water can be managed, changes in the future	4	3	12	Northern Water sets annual quota. Method of setting quota could change, especially with transition to more municipal ownership.
A4	Changing state administration	Policies around state water administration change, impacting yields from water rights	5	3	15	Policy changes could affect shrink applied to conveyance, water rights transfers, etc. in ways that would reduce yield from the City's existing rights or reduce yield from future acquisitions.
A5	Water Court Risks to existing decrees	Existing water rights are challenged in court, potentially changing their availability	5	2	10	More of a concern in the future as competition for scare water resources increases.
A6	New Regulations - Endangered Species	New regulations impact availability of yields from existing water rights and ability to permit new projects	3	3	9	Primary concern would be ability to permit new water projects.
A7	Public Trust Doctrine	Colorado water law is fundamentally changed, eliminating the prior appropriation system	1	5	5	Yield from all current City water rights and rights of other water users in the basin would suddenly be uncertain.
A8	Yields reduced in future change cases	Less water is realized from future water rights as assumed yields are greater than actual. FCU doesn't anticipate acquiring new water rights so risk is low.	4	1	4	Fort Collins has already done most of their change cases and expects a minimal amount in the future.
A9	Elimination or Interruption of Reuse Plan	Platte River Power Authority decommissions Rawhide Energy Station, effectively eliminating the need for the Reuse Plan. In multi-year droughts, water from the Reuse Plan is reduced or unavailable.	4	3	12	Current response to Reuse Plan being developed by FCU.

A.5 Demands

The following table presents the demand risks and uncertainties identified by FCU and their associated scores and additional notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
D1	Service area growth and Regionalization	Ft. Collins expands its service area or enters into agreements to provide water to regional entities.	3	5	15	Increased water demands must be met and service connections extended.
D2	Water use changes	Decrease in per capita use continues and how water is used (e.g. indoor vs. outdoor) changes	5	3	15	Continuation of recent trends in less per capita residential use and less outdoor use relative to indoor use.
D3	Development Uncertainty	The composition of development in service area (e.g. density, type, outdoor area) is different that past.	5	3	15	Increased density is anticipated with redevelopment in some areas and higher land values.
D6	Hotter summer changes irrigation	A warmer climate increases the length of the irrigation season and hotter days increase demand during the summer.	4	3	12	Affects City demand and demand by other users in the basin.
D8	Change in precipitation type	More precipitation falls as rain instead of snow during the Fall and Spring.	4	3	12	Affects irrigation demand in City service area and in region.
D9	Changes in frequency/ magnitude of precipitation events	Precipitation events become less frequent and more intense	4	3	12	Higher summer rainfall could affect demand patterns.
D4	Landscape Changes	Changes in outdoor landscaping (e.g. xeriscape) change demands from past	3	3	9	Reduction in outdoor use and irrigation season demand.
D5	Decreased water restriction effectiveness	Watering restrictions become less effective at temporarily reducing demands.	3	3	9	Demand hardening with less outdoor demand and other non-critical demands.
D7	New Large Users	A new, non-regional water user is brought on in the service area.	3	2	6	New commercial or industrial user similar to AB or HP.
D10	Changes to Existing Obligations	Existing large water contracts change or end	3	1	3	Major industrial user moves out of town, or converts to raw water rather than potable water.

APPENDIX B – NORTHERN WATER RISK AND UNCERTAINTY TABLES

B.1 Climate and Hydrology

The following table presents the climate and hydrology risks and uncertainties identified by Northern and their associated scores and additional notes

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
CN1	Longer Duration Droughts	Long-term droughts that have longer durations than occurred in past.	4	5	20	Quotas would be set high for first few years to meet allottee requests, but in later dry years they would be lower than requested based on limited water availability. The third year of a drought will be hardest to meet with quota system. Anticipated that allottees will adjust their own water use to account for long duration drought.
CN2	Increased frequency of extreme dry years	Years like 2002 and 2011 become more frequent	4	4	16	Single extreme dry years will be more impactful on Windy Gap than C-BT. System can absorb 1-2 years of these types of drought years without impacting quotas due to large amount of storage in C-BT.
CN3	Changes in runoff volume	Long-term reductions in runoff volume due to hotter, drier climate reduce overall yield. Northern has sufficient storage to capture this and its water rights are not specific in time.	3	4	12	Historical examples in 2002 and 2012 had lower runoff due to sublimation of snowpack in a hot Spring. Climate models suggest hotter future in Upper Colorado River basin.
CN4	Changes in runoff timing	Runoff volumes shift earlier in the Spring/Summer with peak runoff occurring earlier.	5	2	10	This situation is already occurring compared to historical records. C-BT and Windy Gap West Slope water rights are not dependent on timing of runoff. However, East Slope water rights may yield less water due to earlier filling of storage facilities.
CN5	Increased Evaporation in Reservoirs	Temperature increase results in increased evaporation losses from reservoirs.	5	2	10	Most facilities are at higher altitudes with low evaporation losses, so even large percentage increases in evaporation rate would not result in significant reductions in yield.
CN6	More precipitation as rain	More precipitation falls as rain instead of snow. The impacts on yields and runoff are uncertain due to complex watershed processes.	5	2	10	Willow Creek Reservoir on West Slope is at risk of spilling due to flashy rain events.

B.2 Watersheds

The following table presents the watershed risks and uncertainties identified by Northern and their associated scores and additional notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
WN1	Changes in wildfire characteristics	Increase in extent and severity of wildfires in high elevation forests degrades water quality, increases sediment loads and changes runoff characteristics	5	4	20	Lake Granby more vulnerable to O&M impacts; Grand Lake and Shadow Mountain Reservoir more vulnerable to WQ impacts. Lack of recent fire in area increases potential negative impacts. Hot burns creating hydrophobic soils are most problematic.
WN2	Wildfires - Upstream of Grand Lake/Shadow Mountain	Increased occurrence of wildfire leads to short term reduced capacity and ability to use Grand Lake/Shadow Mountain Reservoir. Long term channel and sediment changes.	4	4	16	Increased sediment loads, water quality issues, debris flows.
WN3	Watershed forest health degradation	Poorer forest health leads to increase in wildfire risk, water quality impacts, hydrology impacts and increased sediment load.	5	3	15	Already occurring due to hotter climate and bark beetle infestation. Degraded forest affects runoff quality, generates more sediment, and increases total volume and accelerates timing of runoff.
WN4	Wildfires - East Slope	Increased occurrence of wildfires in Big Thompson River basin degrades water quality and may prevent ability to use Big T to move C-BT water. Watershed above Lake Estes has lower wildfire impact risk but higher likelihood.	4	3	12	Loveland in 2017 wasn't able to utilize their C-BT water due to water quality issues in Big Thompson. Some impacts can be bypassed using Power Arm.
WN5	Increased sediment loading	Increased sediment loading from several causes reduces reservoir or conveyance capacity and affects water quality.	4	3	12	Shadow Mountain has highest water quality risk. East Slope facilities have lower risk and can be more easily mitigated. Sediment accumulation impacts water deliveries from reservoirs less than canals.
WN6	Flooding	Major flooding events cause mostly short term impacts during which water cannot be used due to compromised water quality.	5	2	10	September 2013 is a recent example of impacts. Most facilities are robust against flooding and have redundancy in the system.
WN7	Development in Fraser Valley	Residential development increases water quality risks due to urban runoff, return flows and more septic systems.	4	1	4	Potential for urban development in Fraser Valley is greater than around Lake Granby, Shadow Mountain and Grand Lake. Fraser River is tributary to Upper Colorado upstream of the C-BT and Windy Gap pumping plants that pump water into Granby and ultimately Adams Tunnel.
WN8	Wildfires - East Slope Reservoirs	Wildfires in East Slope reservoir watersheds (e.g., Horsetooth Reservoir watershed) affects water quality, sediment loading and runoff characteristics for drainage into the reservoirs.	4	1	4	Past events in the Horsetooth Reservoir watershed and others have had low impact on water quality or sediment due to ability to implement mitigation measures.
WN9	Development above Lake Granby	Residential development increases water quality risks in Lake Granby and Tri-Lakes system.	3	1	3	Minimal space is available for new development to occur, which reduces impact of risk.

B.3 Operations and Infrastructure

The following table presents the operations and infrastructure risks and uncertainties identified by Northern and their associated scores and notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
ON1	Green Mountain Replacement Pool Inadequacy	With changing hydrology the 52,000 acre-ft replacement pool may be inadequate to mitigate against a variety of future risks.	4	4	16	Due to hydrologic uncertainty in the Colorado River, the efficiency of the 52,000 acre-ft pool to replace C-BT system out of priority depletions could be affected. Key element of Northern's West Slope operations.
ON2	Unit No3 of Flatiron Facility Outage	Failure of Unit 3 in the Flatiron Pump Station prevents pumping water into Carter Lake	4	3	12	
ON3	Power Arm Outage	Failure of Power Arm prevents moving water into Carter Lake	4	3	12	
ON4	Southern Water Supply Project Outage	Failure of Southern Water Supply Project prevents delivering water to southern allottees	3	4	12	This affects distribution pipes and canals but not C-BT or Windy Gap yield.
ON5	EPA Transfer Rule	New EPA policy on transbasin diversions makes all existing and future C-BT/Windy Gap subject to discharge requirements	2	5	10	Would require new/increased treatment to meet discharge standards and could reduce yields of water quality requirements could not be met.
ON6	East Slope Water Rights Uncertainty	Runoff timing changes or increased basin demands impact Northern's yields from East Slope rights and change operation of reservoirs.	3	3	9	
ON7	Power Transmission Lines Outages	Wildfire or other emergency causes outage in transmission lines providing power to C-BT/Windy Gap pump stations.	3	3	9	Would take affected pump stations offline for a short period of time (< 1 year)
ON8	Algal Blooms	Increased nutrients and temperatures cause algal blooms in reservoirs, impacting suitability of water supply for potable uses	4	2	8	Potential effects include cyanobacteria and taste/odor issues.
ON9	Aquatic Plants	Increased nutrients and invasive plants grow in reservoirs and canals, impacting operations and potentially increasing treatment requirements	4	2	8	Potential effects include increased treatment requirements, decreased canal capacity, changes in operations. Requires drawdowns of reservoirs for maintenance, restricting operations.
ON10	Invasive Species - Mussels	Mussels clog inlet/outlet pipelines which combined with lack of redundancy may cause short term outages.	2	4	8	Once species invade they cannot be removed. Water providers in other parts of state have successfully managed or mitigated this issue.
ON11	Grand Lake Clarity	Managing to meet clarity requirements leads to less operational flexibility in the system.	4	2	8	May lead to fewer days of diverting through Adams Tunnel, increasing spills from West Slope reservoirs and lowering overall yield.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
ON12	Conveyance Systems to Horsetooth Outage	Variety of events could cause outages or reduced in deliveries in conveyance system components to Horsetooth Reservoir	2	4	8	
ON13	Power Generation vs. Water Delivery Operations	Power generation may be given preference over delivering water in C-BT operations	2	4	8	Current priority is for water delivery with incidental power generation, but that could change in the future.
ON14	Grand River Ditch Breach	Failure of the ditch brings sediment into Shadow Mountain/Grand Lake that causes operational changes.	2	3	6	Linked to Grand Lake Clarity issues.
ON15	Conveyance Systems from Carter Lake Outage	Variety of events could cause outages or reduced deliveries from Carter Lake	2	3	6	This is a delivery system problem. No effect on C-BT/Windy Gap yield.
ON16	Boulder Reservoir Shared Operations	Increased constraints due to Boulder operations impacts ability to deliver water to southern allottees.	2	3	6	
ON17	Farr Pump Plant Outage	Pump station failure prevents moving water from Lake Granby to Grand Lake and Adams Tunnel.	1	5	5	
ON18	Adams Tunnel Outage	Tunnel failure prevents moving all C-BT/Windy Gap water to East Slope.	1	5	5	The Adams Tunnel is the only way for NCWCD to access their West Slope Supplies. However, it is well maintained and unlikely to experience and outage (other than planned). If an outage were to occur this would be catastrophic with no alternative.
ON19	Lake Granby Dam/Dike System Outage	Reduced capacity due to safety reduction or other outage issue limits ability to move water to Grand Lake and Adams Tunnel	1	5	5	
ON20	Windy Gap Plant Outage	Pump station failure prevents transfer of Windy Gap water into the C-BT system	1	4	4	
ON21	Power Arm and Dille Tunnel Failure (Concurrent)	Concurrent failure of both conveyance facilities would prevent delivering water to Horsetooth.	1	4	4	Would need to occur in combination to completely prevent delivering water to Horsetooth Reservoir.
ON22	Willow Creek Pump Plant Outage	Pump station failure prevents pumping C-BT water into Lake Granby and reduce system yield	1	3	3	

B.1 Legal and Administrative

The following table presents the legal and administrative risks and uncertainties identified by Northern and their associated scores and notes

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
AN1	Environmental Regulations (changes, new, compliance)	New regulations or changes in federal permitting compliance may lead to more water used for environmental mitigation/flows.	3	4	12	Combination of Federal Permitting Compliance (NEPA, ESA Section 7, USACE 404) and New Endangered Species risks. Critical habitat for listed threatened/endangered species designated within watersheds. This could lead to additional water being unavailable to meet environmental flow needs--or for replacement infrastructure to be inaccessible.
AN2	Colorado River Hydrologic Uncertainty / Major Outage of C-BT Project	Possible changes in C-BT operations based on hydrologic uncertainties and a large C-BT Project outage	2	5	10	Combination of several possible conditions resulting in decreased deliveries from C-BT Project water to allottees. These scenarios are intended to assess the impact of outages of major C-BT delivery systems or reduced diversions caused by reduced flows in the Colorado River that are not dependent on currently unknown future hydrology or legal requirements.
AN3	Windy Gap renegotiation	When current 40-year contract limit expires, a renegotiated contract gives less yield (due to increased shrink for example)	5	2	10	
AN4	Federal law requires modification of Project Operations	Federal law requires changes in how the C-BT Project is operated (e.g. for endangered species, power), reducing C-BT/Windy Gap yield	2	4	8	

B.1 Demands

The following table presents the demand risks and uncertainties identified by Northern and their associated scores and additional notes.

ID	Risk or Uncertainty Name	Description	Likelihood Score	Impact Score	Composite Score	Notes
DN1	Longer Growing Season	Hotter, drier climate lengthens the growing season for agricultural and M&I allottees, increasing their demands and changing when they need C-BT/Windy Gap water	5	2	10	This is already occurring. Allottees not directly connected can only take water from April 1 - November 1. That's a policy that could be changed. May change how quotas are used and increase overall basin demand.
DN2	Changes in C-BT Users	Continued shift in C-BT ownership to M&I users, who would want quotas set differently than agricultural users.	5	1	5	M&I allottees emphasize use as a reliable water supply which would lead to increased carryover in system and desire for overall lower quota. Ag allottees emphasize higher use in drier years as a supplemental water supply as originally intended.
DN3	Uncertainty of Setting Quota	Change in ownership and Board membership changes the process by which quota is set. May be narrower range to satisfy M&I allottees.	3	1	3	May need to explore different quota policies since the nature and direction of changes is uncertain.
DN4	Increase in quota use	Quotas are not set as high, but as time goes on actual water use is closer to the quota amount.	4	1	4	This is already occurring.
DN5	Northern Water Management Program Changes	Changes to the Annual Carryover Storage program or Regional Pool program occur, making water management for M&I allottees less flexible.	3	1	3	Would only occur due to West Slope interests or Federal operations change. M&I allottees prefer more flexibility so any changes are likely to have minimal effect.

Appendix C WATER DEMAND FORECASTING TOOL TECHNICAL MEMORANDUM

City of Fort Collins Utilities
Water Vulnerability Study

Technical Memorandum

Demand Estimation Documentation

Date: March 8, 2019 (Revised May 13, 2019)

From: Zelalem Mekonnen, Jason Polly and Enrique Triana
RTI International

To: City of Fort Collins Utilities

1 Introduction

This technical memorandum documents the main aspects of the demand estimation tool developed as part of the Water Supply Vulnerability Study for the City of Fort Collins Utilities (FCU). The development of the demand estimation tool incorporates the variables and computation algorithm used in the demand model, which was developed by FCU staff with data provided by RTI. The demand model consists of individual linear regression models developed for the main water customer users, i.e., single family and duplex, multifamily, commercial small, commercial medium and commercial large. The models were developed with processed water use from 2001-2016, which corresponds to the set of available years with complete water user data. The underlying data for the tool is derived from spatial processing of GIS layers and groupings of the variables by areas and sectors matching the demand models.

2 Data Processing Summary

2.1 Raw Data Source

Raw water use data from 2001 to 2016 provided by FCU was processed spatially using GIS premise (customer) points overlaid with parcels, and linking it to features associated with both the parcels and the premises, for example, building characteristics, irrigated areas, service areas, water districts. The spatial process resulted in a GIS summary table—the "Master Table"—that is imported into the water use database and is used by the demand estimation tool.

2.2 Water Use Database

The water use data was compiled into a water use database for this project. The water use database is maintained on the FCU server and it was used for data processing and data storage, as well as to develop the demand estimation tool. Table 1 provides general information about the database. This database includes imports of the raw use data, imports of the GIS Master Table, and preferences and scenarios of the demand models.

Table 1 – Water Use Database Information

SQL SERVER	10.100.0.87\DEV16
DATABASE NAME	FCU_WaterUseProcessing

2.3 GIS Master Table

The Master Table combines the spatial characteristics related to water use and demand estimation variables at a parcel resolution. It was developed to support the demand estimation tool and provides improved flexibility in calculating the elements of the demand. This table is composed of rows that represent polygons with unique water use characteristics.

2.3.1 Master Table Development

The Master Table refers to a single table resulting from a series of spatial and tabular process steps. The process was designed to relate water demand information to City of Fort Collins parcels. The development of the Master Table was performed in a GIS environment as most data inputs were spatial in nature and were not available within a pre-existing relational database.

2.3.1.1 Background

To construct the Master Table, RTI acquired pre-existing GIS layers from the City of Fort Collins. A demand model GIS database was developed to store raw data and resulting outputs. A GIS model was developed to process the raw data and produce the processed Master Table with related information.

2.3.1.2 Data Inputs

Table 2 lists the raw data used as base GIS layers.

Table 2 – Input Raw GIS Layers

LAYER ID	LAYER DESCRIPTION
1	Buildings
2	City Limits
3	Fort Collins Service Area
4	Growth Management Area (GMA)
5	Hydro
6	Natural Areas
7	Parcels
8	Water Districts
9	Zoning
10	Future Land Use Zoning
11	Meters
12	Traffic Analysis Zones (NRFMPO TAZ)

2.3.1.3 Development Framework

The framework used for developing the Master Table involved ESRI ArcGIS desktop software version 10.5. Within the software, an ESRI geodatabase was designed and populated with the raw data inputs. Feature datasets were used to separate data by source and type. ModelBuilder was then used to develop geoprocessing steps needed to relate layers under specific environments.

2.3.1.4 Model Steps and Results

Within ModelBuilder, a series of geoprocessing steps was constructed as outlined in Table 3.

Table 3 – High-Level Overview of Processing Steps Used in the Model

STEP ORDER	DESCRIPTION
1	Join Zoning to Parcels
2	Select Parcels by GMA
3	Dissolve on Shape
4	Add Unique Parcel ID

The final output GIS layer contains related information based off each tabular and spatial step. The polygons represented in the Master Table and the Growth Management Area (GMA) boundary are shown in Figure 1. The final GIS layer attribute table, or Master Table, was imported into the water use database in the ***MasterTableGISExport*** table. The Master Table plays an important role in the demand estimation method providing information about current densities in planning zones for future predictions of water use in undeveloped areas. Also, the Master Table allows grouping of current use and estimated water use by planning zones and areas of the city, such as FCU service areas, city limits, and GMA. Some of the main assumptions in the Master Table data and processing are:

- The planning zones are taken from the current data and areas without current planning zone classification are assigned with the future planning zone estimate.
- The GIS layers are current and complete.

The attribute table was then exported to be used within the demand analysis.

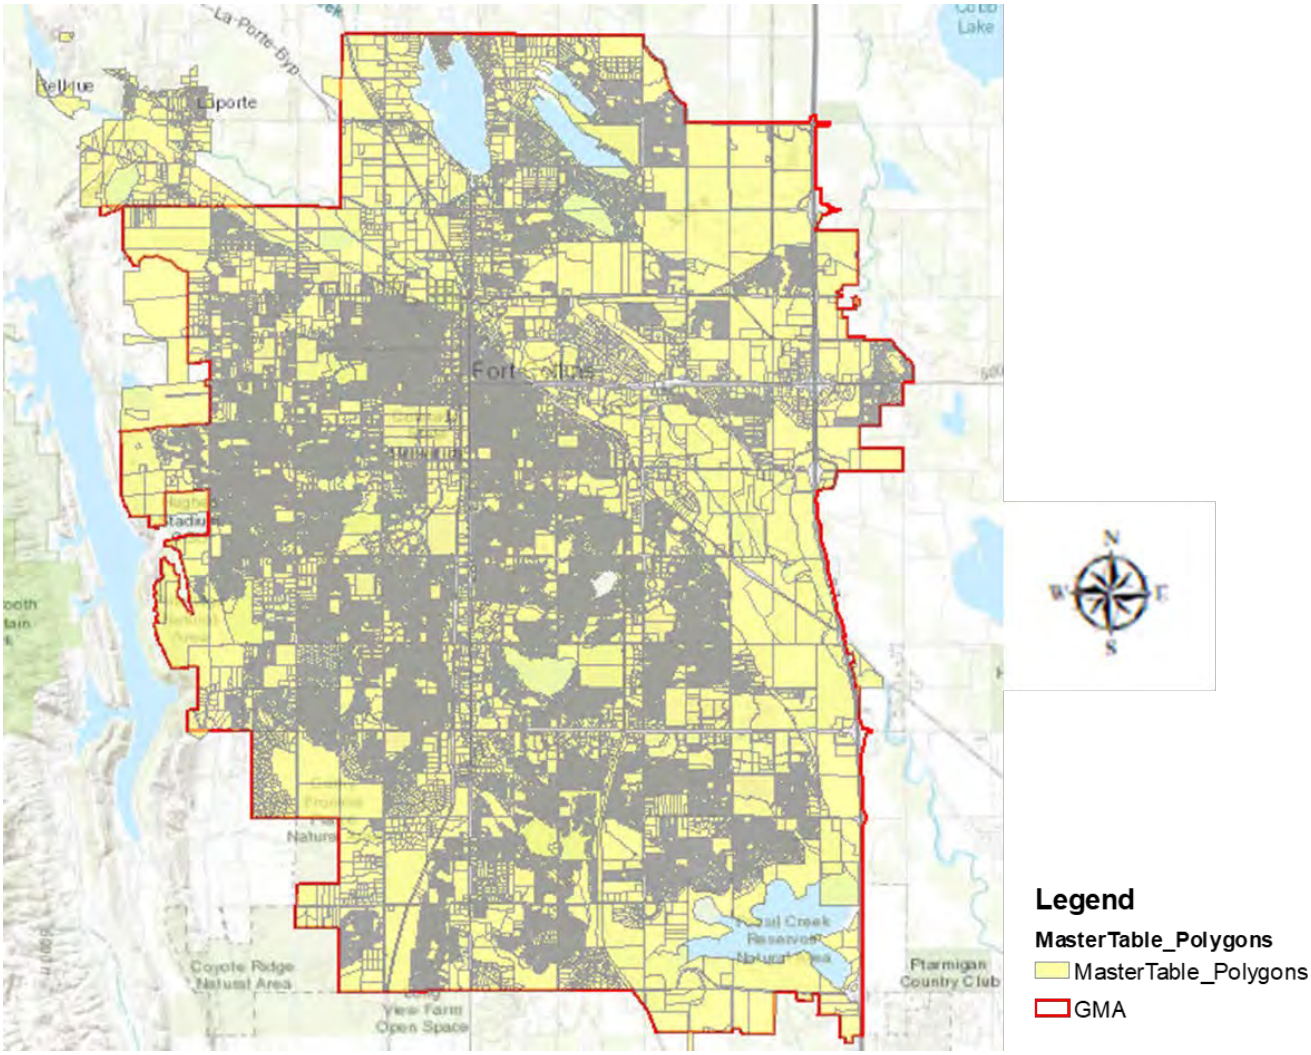

Figure 1 - Master Table Polygon Extent

Table 4 lists the fields and the different sources for each polygon in the Master Table.[1] Although not all the fields included in the current Master Table are used in the demand estimation model, the information in the table was left there for future reference and analyses.

[1] Polygons in the Master Table refer to parcel polygons from the city and county, identified by a unique parcel number.

Table 4 – Master Table Fields

FIELD	SOURCE	UNITS (if applicable)	DESCRIPTION
ZONE	City Current and Future Zoning	Zone Type	Spatial join of zone layers to parcel (current method for this field, only uses the current city zoning layer) values are null for nonzoned locations. Null values are filled with future zones from the Planning Department.
PARCEL_ID	Unique Parcel ID (RTI)	ID	RTI calculates a unique parcel ID for general tracking.
AREA	City Building	Sq ft	Area of building (footprint) within parcel using City building layer.
PERCENTAGE	Building Percentage	Percentage	Percentage of parcel covered by building (footprint).
PNT_COUNT	Count of premises, per parcel	Count	Tabular summary of premises within a parcel. Note, parcels with no premise are set to 1.
ZONE_DISTR	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
VACANT_AC	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
REDEV_ACRE	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
RES_LUM	Source 2017 re-development worksheet		Residential Land Use Mix – represents the percent of area in the zone that is residential. This parameter is used in the calculation of DEMAND_DU in the Master Table.
NONRES_LUM	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
AVG_DEN_DU	Source 2017 re-development worksheet		A field from the planning density table (used for join on zone type). Provides density values per zone.
AVG_DEN__F	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
DWEL_UNIT_	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
DWEL_UNIT1	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
NONCAP	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
NONCAP_SQ_	Source 2017 re-development worksheet		A residual field from the planning density table (used for join on zone type), not of use.
SDP	Premise (Meters) GIS layer		Spatial join (Premise-Parcel) using City (Meter/Premise) layer.
PREMISE	Premise (Meters) GIS layer	ID	Spatial join (Premise-Parcel) using City (Meter/Premise) layer.
SERVICETYP	Premise (Meters) GIS layer		Spatial join (Premise-Parcel) using City (Meter/Premise) layer.
SERVICECOD	Premise (Meters) GIS layer		Spatial join (Premise-Parcel) using City (Meter/Premise) layer.

FIELD	SOURCE	UNITS (if applicable)	DESCRIPTION
ADDRESS	Premise (Meters) GIS layer		Spatial join (Premise-Parcel) using City (Meter/Premise) layer.
CUSTOMERCO	Premise (Meters) GIS layer		Spatial join (Premise-Parcel) using City (Meter/Premise) layer.
STATUS	Premise (Meters) GIS layer		Spatial join (Premise-Parcel) using City (Meter/Premise) layer.
GMA	City GMA Layer		Spatial join (GMA-Parcel) (Null if outside) using City GMA layer.
SERVICEARE[2]	City Service Layer		Spatial join (Service Area-Parcel) (Null if outside) uses City Service Layer).
CLIMITS	City Limits Layer		Spatial join (City Limits-Parcel) (Null if outside) uses City Limits Layer.
PARCEL_ACR		acres	GIS area calculation (Parcel).
DEMAND_DU	Dwelling Unit Calculation		Used for checking the number of dwelling units for demand calculation ([Acres] * [Res_LUM]) * [Avg_Den_du_a].
DEMAND_POP	Population Calculation	Count	(([Acres] * [Res_LUM]) * [Avg_Den_du_a] * 2.37) / [PNT_COUNT].
HYDRO	Water Bodies GIS Layer		Spatial join, identifies parcels with a water body.
F_LU	City Future Zoning GIS Layer	Zone Type	Spatial join on future layers to parcel (Current method for this field, only uses the future zoning layer).
EMPDEN_12	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
EMPDEN_15	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
EMPDEN_20	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
EMPDEN_25	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
EMPDEN_30	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
EMPDEN_35	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
EMPDEN_40	NFRMPO_TAZ_12to40		Employment density (Assumed SqMi).
IRR_ACRES	WV2 imagery and LiDAR data	acres	Outdoor irrigation classification.

2.4 Water Use Processing

2.4.1 Water Use Process

The customer water use data used for the Vulnerability Study was provided by FCU, and initially processed by a group at Colorado State University (CSU) as part of a parallel effort. The residential single-family, multi-family, and commercial datasets for the FCU service area were provided in three different batches and imported into the ***RawWaterUseResidential***, ***RawWaterUseMultiFam***, and

[2] This attribute in the current Master Table was generated from the original service area map and was not updated with a revised service area provided in 2018. This attribute is used to group the parcels by utility service area and will need to be updated in the future with revised service area map.

RawWaterUseCommercial tables of the database. The modeling management system includes a processing algorithm with a user interface (Figure 2).

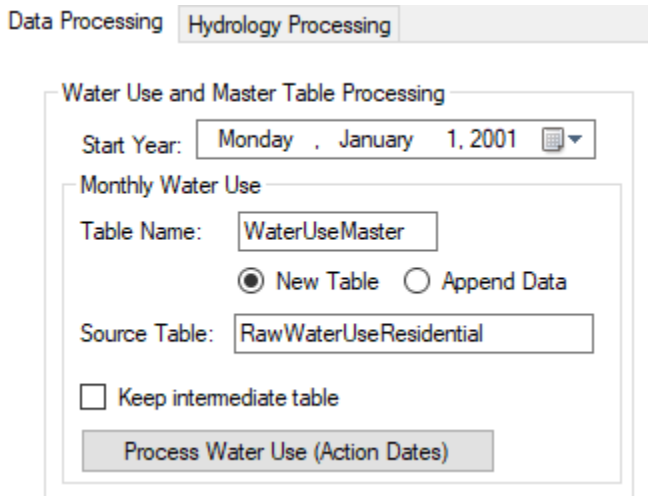

Figure 2 – Water Use Processing Algorithm User Interface

Each entry of the raw water use data includes an action date and days of service (DOS). Missing action dates were filled using the CSU-processed dataset. The water use meter readings for a customer, or premise, are typically around a month apart. However, in some cases, the reading includes multiple months in the DOS. RTI developed an algorithm to process the water use data to generate an approximation of the monthly water use per premise. The algorithm was implemented using SQL queries and VB.NET code. The main steps of the water use processing algorithm are:

1) For each record of water use in the imported data, the '***previous date'*** is calculated as the action date minus the DOS.

2) Average water use per day is computed by dividing the consumption in gallons (i.e., **Consumption** field in the raw data table) by the DOS.

3) The number of days in the action month (i.e., the number of days from the beginning of the month to the action date), is multiplied by the average water use per day found in step 2 to calculate the partial water use in the action month.

4) Water use from the previous month or months to the action month, included in the DOS, are computed based on the average daily consumption calculated in step 2 and the number of days from the 'previous date' to the end of the month, or months if more than one is included in the DOS.

5) The monthly water use is estimated by aggregating the water use estimates for each portion of the month between readings.

The results of the water use data processing are stored in the water use database in the ***WaterUseMaster*** table. Some multifamily complexes are coded as single commercial users in the water use dataset; therefore, the processing of the water use data included recoding the rate code of multi-family premises that have a rate code as commercial in the raw water use dataset. The list of commercial premises that were converted to multifamily rate code (i.e., W260) for the demand

calculation are included in Appendix 1. This change was performed in the ***WaterUseMaster*** table. The list of premises was compiled and provided by FCU and includes information about the type of use (e.g., irrigation, club, indoors). Note that the revenue from the raw water use data is also processed into the ***WaterUseMaster*** table, summarized by month.

2.4.2 Commercial Customer Groups

The size of the taps associated with the rate code were used to group the commercial water use as Commercial Small (CM_Sm), Commercial Medium (CM_Md), or Commercial Large (CM_Lg). Table 5 shows the rate codes for commercial taps with the corresponding group.

Table 5 – Rate Code Groups for Commercial Premises

3 Demand Estimation Approach

This section describes the main elements for estimating future water demand for the Vulnerability Study. This section is organized following the sections of the graphical user interface (GUI) for the demand estimation tool. Figure 3 shows the GUI of the demand estimation tool.

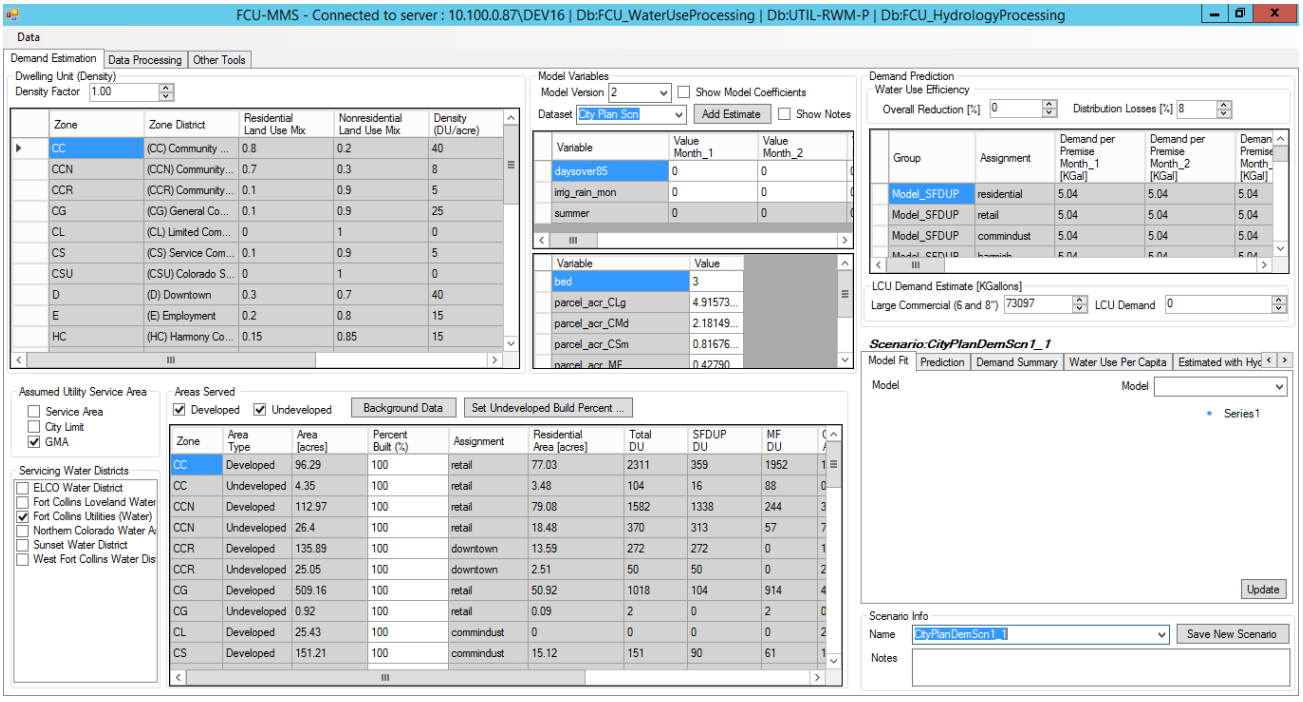

Figure 3 – Main Window of the GUI for the Demand Estimation Tool

In this section, this icon identifies user inputs and knobs implemented for the demand estimation.

The GUI displays read-only fields with gray background and fields with white background are user inputs that are saved as part of the demand scenarios.

3.1 Demand Models

Monthly demand models were developed by FCU using the processed water use data and customer groupings described in Section 2. A set of five models were developed to predict the average water use per premise per month, one model for each of the five water user types. The models estimate water use for single-family and duplex (***SFDUP***) customers, multi-family (***MULTIFAMILY***) customers, commercial small (***CM_SMALL***) customers, commercial medium (***CM_MED***) customers, and commercial large (***CM_LARGE***) customers. The models were developed using multi-regression linear equations and the independent variables were selected based on the expected influence on the water demand and the statistical significance in the regression equation. Table 6 lists the independent variables used in the demand models and provides a brief description of each variable.

Table 6 – List and Description of Variables Used in the Demand Models

VARIABLE NAME	DESCRIPTION
(INTERCEPT)	Equation constant
BED	Number of bedrooms
COMMINDUST	Equals 1 if primarily an industrial or commercial zone
DAYSOVER85	Numbers of days in the month with the max temp over 85
DOWNTOWN	Equals 1 if primarily a downtown zone
HARMISH	Equals 1 if primarily a harmony corridor or employment zone
IRRIG_RAIN_MON	Total rain in the month, only for May through September, equals zero for the other months
PARCEL_ACR_CLG	Parcel size, acres for large commercial
PARCEL_ACR_CMD	Parcel size, acres for medium commercial
PARCEL_ACR_CSM	Parcel size, acres for small commercial
PARCEL_ACR_MF	Parcel size, acres for multi-family parcels
PARCEL_ACR_SMDUP	Parcel size, acres for single family and duplex parcels
RESIDENTIAL	Equals 1 if primarily a residential zone
RETAIL	Equals 1 if primarily a retail zone
SUMMER	Equals 1 if May through Sept
UNEMPRATE	Unemployment rate (monthly)
UNITS	Numbers of units

Table 7 shows a matrix of coefficients for each model and associated independent variable. The cells without a coefficient indicate that the variable is not being used in the corresponding equation.

Table 7 – Multi-Regression Coefficients for Each Variable for Each Demand Model

3.2 Future Premises Estimation

The approach uses the density of dwelling units per acre per planning zone as the basis to estimate the number of premises by zone.

3.2.1 Dwelling Units Density

3.2.1.1 Dwelling Units per Zone

The densities provided by the Fort Collins Planning Department include assumptions on the city's projected infill and vertical growth per zone. Therefore, by using these densities, the user is considering a future growth characteristic.

The Planning Department also provides a residential and non-residential percentage for each zone. The estimation of dwelling units (DUs) is based on the estimated area per zone and the '***Residential Land Use Mix***' value provided by the Planning Department. Premises are associated with water user accounts. Single family residential units are usually associated with a single premise, duplex units could have multiple premises but for this analysis those are assumed to have a single premise. Typically, multifamily complexes have multiple DUs and fewer number of associated premises, with some premises (accounts) used for club houses and pools.

Density Factor The user can use the ***Density Factor*** to evenly reduce or increase all the densities simultaneously to simulate sensitivities around the base future density conditions for the demand estimation. A ***Density Factor*** of 1 is equivalent to the future densities provided by the Planning Department. This factor is applied to the base densities to create the '***Active Density***' value for each zone, which is used in the demand estimation.

Active Density This variable allows the user to set the density for each planning zone to be used in the calculation of DUs. These values are affected by the ***Density Factor***; however, these results can be overwritten by user inputs. Note that user values will be overwritten if the Density Factor is changed.

The density (i.e., DUs per acre) and the residential area, determined by the residential and non-residential percentages provided by the Planning Department, are used to calculate the number of DUs per zone ('***Total DU***').

3.2.1.2 Multi-Family Percentage

The multi-family (MF) percentage of the residential DUs ('***MF Percent***') is calculated from the Master Table, using the planning zones and rate codes for residential groups. This calculation is performed for the polygons that are flagged as built, which are premises where the ***Buildable*** field is NULL or 0. Table 8 shows the rate codes used for the single-family/duplex (SF_DU) group and the MF group.

Table 8 – Rate Code and Groups for Residential Premises

RATE CODE	DESCRIPTION	GROUP
W220	Single-family metered	SF_DU
W221	Single-family flat rate	SF_DU
W230	Single-family metered outside	SF_DU
W240	Duplex metered	SF_DU
W241	Duplex flat	SF_DU
W250	Duplex metered outside	SF_DU
W260	Multi-family metered	MF
W262	Master meter	MF
W270	Multi-family metered outside	MF
W272	Master meter outside	MF
W280	Multi-family metered-compound	MF

The number of DUs for multi-family premises is calculated using a representative number of units (DWs) per premise, which is seven units per premise, base on the average of units per multifamily account calculated from the water use data. This average is used in the demand model to estimate the number of premises for the number of multifamily DUs in each zone. For each planning zone, the ***MF Percent*** is computed as the percentage of DUs (i.e., number of premises times the average number of DUs per premise) in each zone with MF rate codes divided by the total number of residential DUs in the zone, calculated as the number of single-family DUs plus the number of multi-family DUs.

3.2.2 Assumed Utility Service Area

There are three service area options available in the demand estimation tool,: (1) FCU service area, (2) city limit, and (3) GMA. These options are used to filter the parcels that are included in the calculation of the served areas for estimating DUs. The groups are defined in the Master Table (see Section 2) and are used to estimate the areas for each planning zone.

The water districts that serve the City and the GMA ('***Servicing Water Districts***') are listed under this option and can be used to further filter the parcels to be included in the demand estimation. Figure 4 shows the spatial extent of the FCU service area, the city limit, the GMA, and the water districts

that supply water within the GMA. Of note, the FCU Service Area attribute in the current Master Table was generated from the original service area map and was not updated with a revised service area provided in 2018 (Fort Collins Utilities Water). This attribute is used to group the parcels by utility service area and will need to be updated in the future with revised service area map.

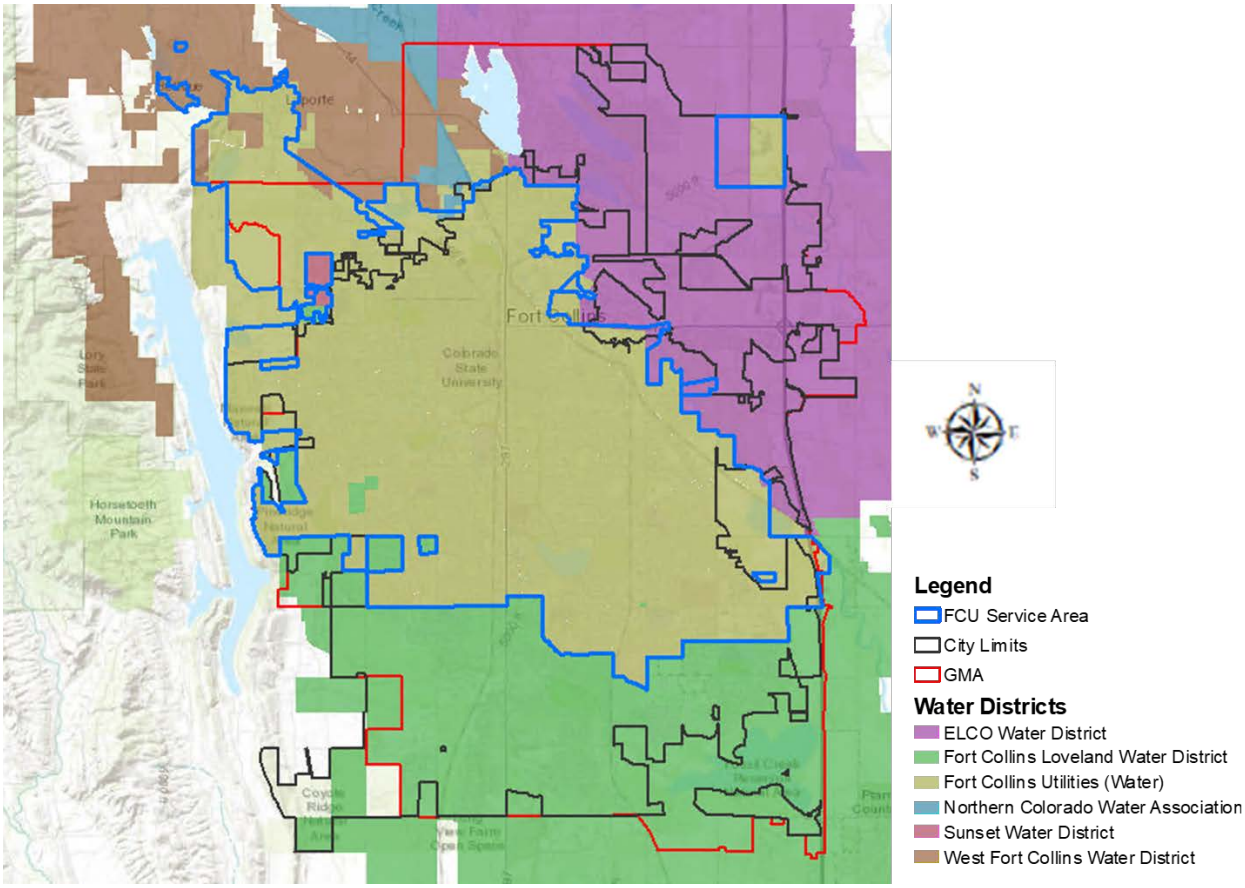

Figure 4 – Spatial Extent of the Service Area, the City Limit, the GMA, and the Water Districts

3.2.3 Areas Served

The Areas Served section includes a breakdown of areas and premises per planning zone and area type, which indicate if the area is currently developed or undeveloped. The areas displayed in this table include the parcels that correspond to the filters in the assumed utility service areas and the water districts served.

The ***Undeveloped*** area type corresponds to the polygons flagged as buildable lands in the Master Table, which are based on the buildable land map from the Planning Department. Figure 5 shows the general location of the buildable areas in the GMA. The ***Developed*** areas are assumed to be the polygons that are not in the buildable areas.

Percent Built

The '***Percent Built***' represents the percentage of the area per zone and area type that is considered for the demand calculations. This parameter is set by the user and allows simulating scenarios prior to build-out conditions, assuming only a fraction of the area selected is served at that time.

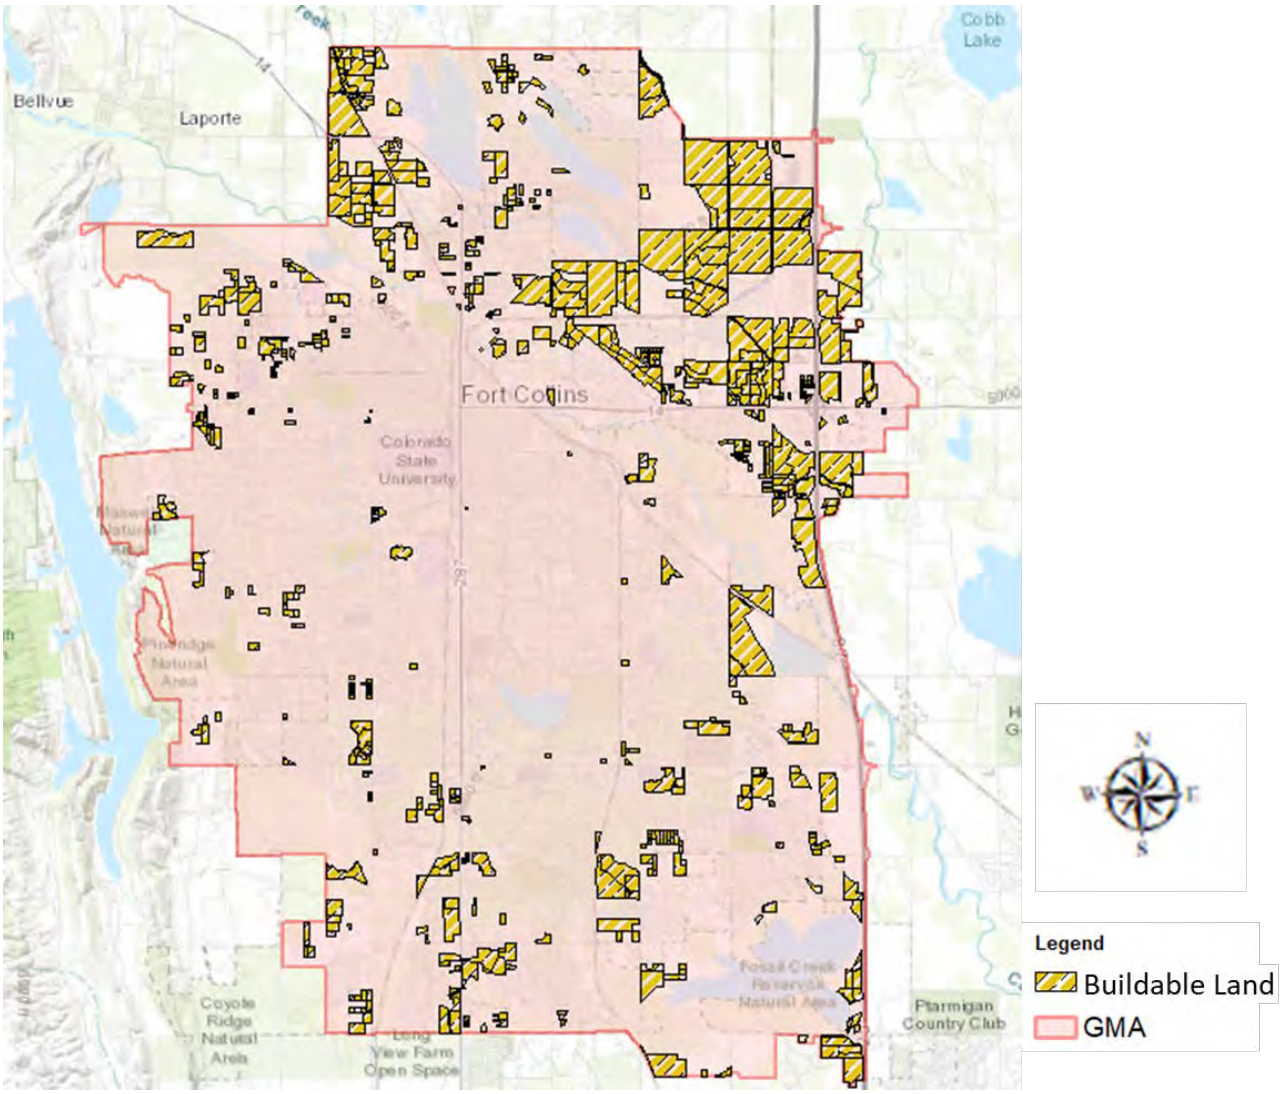

Figure 5 – Parcels Flagged as Buildable in the GMA

The served areas are computed from the Master Table using all the polygons in each zone and grouping them as developed or undeveloped. This calculation includes the spatial filters for water districts and utility service areas, as well as the Percent Built factor. The undeveloped area ('***Area [Acres]***') is computed based on the parcels identified in the buildable layer and the developed areas ('***Area [Acres]***') are calculated from the Master Table for the remaining polygons in the parcel layer in each zone and area type.

The '**Assignment**' is a grouping of the commercial users created to improve the prediction of the demand per premise by the commercial customer models. Each planning zone is put into one Assignment group. Table 9 shows the Assignment corresponding for each planning zone included in the model.

Table 9 – Assignment Group for Planning Zones

ZONE	ZONE_DISTR	ASSIGNMENT
CC	Community Commercial	retail
CCN	Community Commercial - North College	retail
CCR	Community Commercial - Poudre River	downtown
CG	General Commercial	retail
CL	Limited Commercial	commindust
CS	Service Commercial	commindust
D	Downtown	downtown
E	Employment	harmish
HC	Harmony Corridor	harmish
HMN	High Density Mixed-Use Neighborhood	residential
I	Industrial	commindust
LMN	Low Density Mixed-Use Neighborhood	residential
MMN	Medium Density Mixed-Use Neighborhood	residential
NC	Neighborhood Commercial	retail
NCB	Neighborhood Conservation Buffer	downtown
NCL	Neighborhood Conservation Low Density	residential
NCM	Neighborhood Conservation Medium Density	residential
POL	Public Open Lands	nocomm
RC	River Conservation	nocomm
RDR	River Downtown Redevelopment	downtown
RF	Residential Foothills	nocomm
RL	Low Density Residential	residential
RUL	Rural Lands	nocomm
T	Transition	nocomm
UE	Urban Estate	nocomm

3.2.4 Premises per Group

3.2.4.1 Served Area

The demand estimation tool uses the assumed served area to estimate the number of premises and consequently the water demand.

3.2.4.2 Residential Premises

Single-family houses and duplexes are assumed to have a single unit per premise. As is the case with all the regression models, the multi-family water use model predicts water use per premise. Therefore, the number of multi-family units per zone is used to estimate the number of multi-family premises, using the average number of multi-family units per premise for the dataset, which is 7.

3.2.4.3 Commercial Premises

The served area is used to calculate the number of commercial premises, multiplying a calculated density factor, from observed data, by the commercial premises per acre. The current area served per zone is computed from the Master Table using the sum of the parcel polygon areas that have an assigned premise number (i.e., indicating water use in the parcel).[4]

The commercial premises were grouped into small (CM_Sm), medium (CM_Md), and large (CM_Lg and CM_Lg68) taps. Table 5 (Section 2.4.2) shows the rate codes assigned to each commercial group. The number of small, medium, and large commercial premises in each zone is based on the current density of commercial premises for each zone based on the water use data. The current density of commercial premises is computed by dividing the number of commercial premises in each zone by the current area served. The current density of commercial premises per area in each zone is used to estimate the number of commercial premises for each commercial group for each zone, using the total area assumed served in each zone ('***Area [acres]***'), including the user input for ***Percent Built*** for each zone/area type. Using the total area in each zone is consistent with the commercial density values, which are computed based on the total area rather than the commercial area in the zone. The results of this calculation are the number of premises assumed for each zone/area type combination in columns ***Commercial SM Premises***, ***Commercial MD Premises***, and ***Commercial LG Premises***, respectively for each commercial group.

3.3 Annual Demand Estimation per Premise

The annual demand estimate is calculated using the values inputted for the ***Model Variables***. The demand estimation tool stores the coefficients for the regression models in the database. Each model version is identified with a number and is loaded to the GUI when the tool is initialized into the ***Model Version*** box. The model version used for the Vulnerability Study is 2 and was developed by FCU.

Dataset These are groups of input variables stored in the database for each model version. The available datasets are loaded into the GUI when a model version is selected. New can be added to the database by altering the variables of interest, further described below, renaming the dataset in the Dataset box and selecting the **'Add Estimate'** button.

Monthly Values The demand estimation tool requires the user to specify monthly values for the weather variables (***'daysover85'*** and ***'irrig_rain_mon'***). The summer flag (***'summer'***) is a binary variable used to identify the summer months for the demand models. The variable ***daysover85*** corresponds to the number of days with maximum temperate above 85˚F. The variable ***irrig_rain_mon*** corresponds to the total rainfall in the month in inches.

Annual Values These variables are constant for each month calculation, so single values are provided by the user. These variables include the average number of bedrooms per premise (***bed***)[5], the average parcel acreage for each group

[4] For this document, developed polygons are defined as those that are not flagged as buildable from the Planning Department layer; however, not all the developed polygons have a premise, or water use, associated with them, so the area served only contains the parcels with an associated premise.

[5] Data from the County Assessors Data provided by FCU.

(***parcel_acr_CLg, parcel_acr_CMd, parcel_acr_CSm, parcel_acr_MF and parcel_acr_SMDUP***), the unemployment rate (***unemprate***)[6], and average number of units per premise (***units***). A description of each variable is available in the GUI by selecting the ***Show Model Coefficients*** option.

Each model version includes a set of five regression models that independently predict the water use per premise in each customer group ('***Group***') (i.e., single-family/duplex, multi-family, commercial small, commercial medium, and commercial large). Water use in each ***Group*** is calculated for each ***Assignment***, using the monthly, annual, and assignment flag variables. The total water use for each Group/Assignment combination is calculated by summing the premises calculated in the planning zones for each assignment. The calculation of water use per premise for all the groups is affected by a reduction factor, which could be used to represent conservation program effects or general reduction of water consumption not captured by the model independent variables.

Overall Reduction [%]	This is a factor applied to the water use per premise to all the groups simultaneously.

In some specific cases, the simulated water use per premise is truncated to a minimum value to simulate the winter water use when numerically the model regression produces unrealistic low numbers. The two minimum indoor water uses implemented in the demand estimation algorithm are for the commercial small with non-commercial ***Assignment*** and for commercial large with downtown ***Assignment***, which are 3.481 thousand gallons and 40.391 thousand gallons, respectively. These values correspond to the median of the observed water use for those groups and assignments.

3.3.1 Additional Utility Demands

Demands that are not predicted by the five regression models are added as single values by the user.

Large Commercial (6&8")	This user-defined variable represents the total annual demand in thousand gallons of large taps of 6" and 8" not otherwise captured by the LCU Demand.
LCU Demand	This variable represents the annual total demand from Large Commercial User (LCU) contracts in thousand gallons.

These additional demands are assumed to be evenly distributed throughout the year, consistent with the way they have been modeled in previous studies.

3.3.2 Utility Demand Estimation

The annual utility demand is computed by adding the individual demand estimated for each Group/Assignment combination plus the large commercial (6&8") taps and the LCU additional demands. The demand at the water treatment plant is estimated assuming a distribution system losses factor. A typical value for this factor is 8 percent, which is an estimate used in previous

[6] Data from the United States Labor Department (https://data.bls.gov/timeseries/LAUMT082266000000005?amp%253bdata_tool=XGtable&output_view=data&include_graphs=true)

analysis to account for losses from the river to the treatment plant, losses in the treatment process and the distribution losses.

Distribution Losses [%] This factor is assigned by the user and applied to the utility demand to account for distribution and treatment system losses. It provides an estimate the raw water demand at the point of diversion.

3.4 Demand Scenarios

The demand scenarios to be used in the FCU modeling system can be created in the demand estimation tool. A demand scenario includes all the user variables needed to generate the annual demand estimate. The user-defined variables are stored in the ***WaterUseProcessing*** database in the ***DEMScenVars*** table and the scenario preferences are stored in the ***DEMScenarios*** table. The user can save and retrieve demand scenarios using the ***Scenarios Info Name*** box. To select an existing demand scenario, the user can simply select from the available dropdown list. To create a new demand scenario, the user needs to change the variables of interest (all white cells can be altered by the user), input a new demand scenario name in the Scenario Info Name box and select the Save New Scenario button.

3.5 Demand Timeseries for MODSIM

Monthly demand time series for input to the FCU system MODSIM model in the FCU modeling system can be created in the demand estimation tool for the scenarios stored in the database. A demand scenario includes all the user variables described above. A set of these variables is combined with monthly weather variables to generate monthly time series of demand. The weather variables are associated with hydrology ensembles, allowing the simulated hydrology to be synchronized with the demand time series. The weather variables in the demand scenario are populated with a time series of weather variables to generate the sequence of monthly demand values for each hydrology set. The current version of the demand estimation tool generates a set of 86 years of monthly demands, compatible with the Vulnerability Study model simulation period.

3.5.1 Weather Variables

Time series of precipitation and temperature are required to compute the weather-related demand model variables. The hydrology sets developed for the Vulnerability Study capture future variability and climate change, resulting in an ensemble of traces, based on paleo reconstruction of wet and dry periods.[7] Each trace consists of a sequence of possible climate occurrences based on historical monthly precipitation and temperature data that is re-sequenced based on the paleo reconstructed statistics, and then altered to simulate climate change.

The historical daily precipitation and temperature records for the CSU gage, provided by FCU, were used to create the weather time series for the demand estimation tool, using the same sequences used for each hydrology dataset developed for the Vulnerability Study[7]. The variables for the demand models calculated from the daily weather variables are the total precipitation in the month and the maximum daily air temperature in the month. The weather time series for the hydrology datasets were processed and stored in the '***FCU_HydrologyProcessing***' database. The precipitation time series for all the hydrology traces are stored in the '***precip_TS_AllTraces***' table, and

[7] RTI International, 2018. *Future Hydrologic Analysis Technical Memorandum*, Fort Collins, October.

the maximum temperature time series for all the hydrologic traces are stored in the '***temp_TS_AllTraces***' table.[8]

3.5.2 MODSIM Demand Catalog

The demand estimation tool allows processing and adding FCU System MODSIM demand time series to the database for each demand scenario and hydrology trace, to be used by the Modeling Management System (MMS). These time series should be created/cataloged in the database before running the model with the MMS. The demand estimation tool can display the time series in the GUI or import them into the modeling system database. The time series for MODSIM are created in the '***UTIL-RWM-P***' database in the table '***DEMTimeseries.***' This operation is achieved in the '***Estimated with Hydrology***' tab by:

- Selecting '***All Hydrologies***' radial button in the GUI Hydrology section
- Checking the '**Add TS to DB**' option
- Clicking '**Calculate TS.**'

3.5.3 MODSIM Demand

The demand estimation tool creates demand time series for the "Citydem" MODSIM node. This demand time series is created using the same method used in the GUI for a single year, in other words, the "Citydem" time series includes the base demand calculated with the regression equations and the specified conservation reduction factor, the large commercial users with 6" and 8" taps demand and the distribution loss factor applied to the sum of the base demand and the large commercial. The corresponding demand time series for each model run is imported into the '***CityDem***' node at run time, based on the specified demand scenario and hydrology trace. Figure 6 shows a sample of the monthly demand time series generated by the demand estimation tool for a few years, for two ensembles for the base climate scenario (CC Scen ID = 1).

[8] A default ID of '3246' was used for the processed weather variables.

Appendix D HYDROLOGIC MODELING APPROACH TECHNICAL MEMORANDUM

City of Fort Collins Utilities
Water Vulnerability Study

Technical Memorandum

Hydrology Modeling Approach

Date: December 15, 2017 (Revised February 2, 2018)

From: Noah Friesen, Enrique Triana, Jon Quebbeman and Mark Woodbury

RTI International

To: Fort Collins Utilities

1 Introduction

This technical memorandum (TM) describes the approach that will be adopted for generating hydrologic data for use in the Fort Collins Water Vulnerability Study. Hydrologic inputs required for the Vulnerability Study include time series that contain greater variability than the historical record and reflect potential effects of future climate change.

The results of the Climate Change Literature Review TM prepared for the Vulnerability Study and the proposed hydrologic modeling approach were presented to Fort Collins Utilities (FCU) at a workshop on November 13, 2017. The literature review focused on the general approach, and at the workshop it was decided to adopt the bottom-up approach for the Water Vulnerability Study because:

- It is designed specifically to explore vulnerabilities and risk, which is aligned with the goals of the Fort Collins Water Vulnerability Study;
- Its results allow exploring vulnerabilities in the entire uncertain climate domain (Temperature and Precipitation) rather than having to select representative Global Circulation Models (GCM)s;
- Its results are not influenced by the uncertainty of downscaling GCM large-area projections to smaller catchment areas;
- It focuses the analysis on system sensitivities and conditions anticipated to be critical for the system performance;
- It provides flexibility to implement an adaptive planning approach, tracking trends to trigger corrective actions to vulnerabilities for changes registered in a specific direction of the future domain;
- It facilitates analyses of no regret and robust options by exploring the system response to those options for the entire future domain; and
- It allows estimating system performance as climate science evolves by overlaying future GCM predictions on the vulnerability results, without redoing the analysis.

The final hydrology modeling approach, presented herein, considers input from FCU and Northern Colorado Water Conservancy District (Northern), and addresses questions and concerns brought up at the workshop, especially regarding the modeling of Colorado-Big Thompson Project (CBT) basins. The general steps in the modeling approach are:

1. Generate new ensemble traces of precipitation and temperature;
2. Adjust traces to represent a different T and P climate;
3. Run hydrologic models for each trace and each basin;
4. Disaggregate streamflow results to the Poudre Basin Network (PBN) input points and run the PBN model using inputs;
5. Provide the inputs for the CBT quota model.

2 Hydrology Modeling Steps

The hydrology modeling approach presented in this section will be applied to basins required to determine the water availability for the FCU system model, including the PBN model and the CBT model, which generate input to the FCU system model. The basins for which this approach will be applied include: Poudre River basin, Big Thompson river basin, St. Vrain River basin, Boulder Creek basin, Frasier Creek basin, Willow Creek basin and Upper Colorado River basin. Figure 1 shows the locations of the river basins included in the vulnerability study.

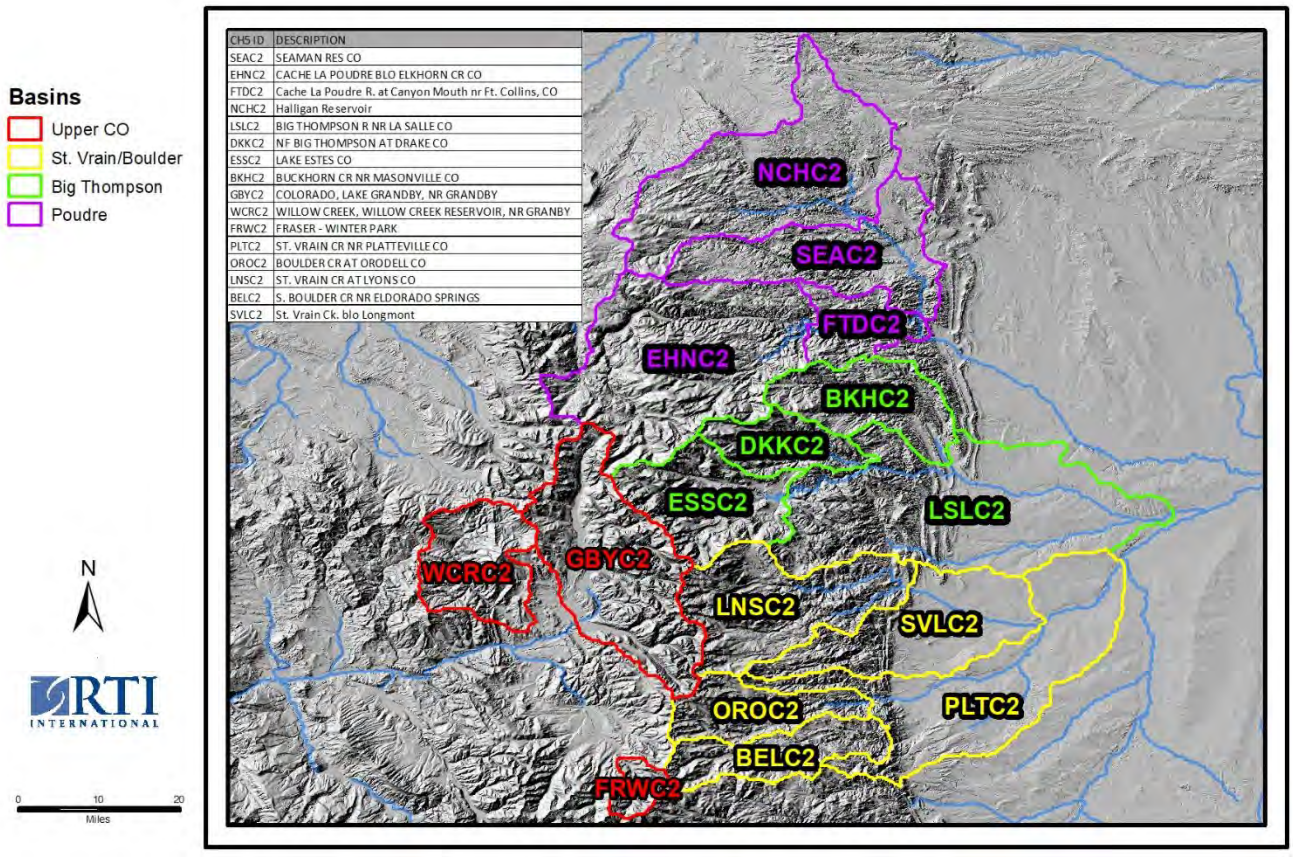

Figure 1 – Map Showing the River Basins included in the Hydrology Modeling for the FCU Vulnerability Study

2.1 Step 1 – Generate Ensembles

The approach to generate precipitation and temperature traces is designed to represent hydrologic variability and future climate change. RTI will generate precipitation (P) and temperature (T) traces based on wet-dry sequence statistics from paleo-hydrology reconstructions. RTI will follow the Block Homogeneous Markov (BHM) technique described by Nowak, Prairie, and Rajagopalan (2007).

RTI will use annual streamflow timeseries for the Poudre River produced by Dr. Connie Woodhouse (University of Arizona) extending back to 1615. This time series will be classified into wet and dry years, using the median annual flow during the observed historical period as the threshold to define wet and dry (Nowak, Prairie, and Rajagopalan, 2007).

RTI will generate 100 traces that are each 86-years long, which corresponds to the current period used in the FCU System model and corresponding data processing tools. Using the BHM procedure, RTI will select an 86-year period from the full paleo period for each of the 100 generated traces. The periods will be selected by sampling periods from the exceedance probability distribution of the representative 43-year running average annual flow from the paleo set to have periods with good representation of the range of wet and dry years estimated in the paleo hydrology. RTI will calculate a matrix of Wet-Dry transitional probabilities using the years in the selected period. The matrix will represent the likelihood that the next year will be dry or wet, based on the current year state. Using a different matrix for each ensemble trace "introduces more drought/surplus variability" (Nowak, Prairie, and Rajagopalan, 2007) compared to using a single matrix and captures more of the multi-year trends that could be washed out using long-term average probabilities. For a given trace, RTI will use the probability of wet and dry years to randomly select a starting state and then use the conditional transition probability matrix to randomly sample the next year type, then use that state to seed the selection of the next period, and so on. This procedure will be used to generate 100 traces of wet/dry year sequences.

RTI will use the models and datasets used in the JFRCCVS. The hydrologic models used in the JFRCCVS were first built for the Missouri Basin and Colorado Basin River Forecast Centers (MBRFC and CBRFC), which includes mean-areal precipitation (MAP) and mean-areal temperature (MAT) time series constructed from individual station records from long-term stations in and near the sub-basins. The River Forecast Centers quality controlled the station data as well as the resulting MAPs and MATs and handled any data filling needs. The time series extend from October 1949 through September 2005 for all the basins to be simulated. RTI will use these same time series and period for this study.

Each month in the observed P and T record will be sorted according to the year type (wet/dry) of the corresponding observed streamflow for that year. All months occurring in wet years will be classified as wet, and all months in dry years will be classified as dry, regardless of the precipitation magnitude of the individual month. For each 86-year trace of wet-dry states, RTI will build the P and T time series month-by-month using the wet/dry sequence and randomly sampling each month from the corresponding observed wet/dry monthly groups. The observed 6-hour precipitation and temperature series from the selected month will be used to create the time series.

For example, if the first year in the trace is wet, we will construct the synthetic year by sampling an October from the wet year group, then a November from the wet year group, etc. If the second year in the trace is dry, we will then sample all months for that year from the dry year groups. Using this procedure RTI will use both the observed precipitation and corresponding temperature to build

the synthetic traces. Sampling this way allows our traces to contain novel years that may be drier or wetter than any observed year, but are still based on actual observed data. The result of this process is the generation of baseline synthetic 6-hour precipitation and temperature series for input to the JFRCCVS rainfall-runoff models that capture the variability of the long-term historical climate.

Using paleo statistics from other basins and randomly sampling months on all the basins would not maintain the spatial correlation of the system time series. Transition probabilities in the South Platte paleo reconstruction will be used to capture the long-term variability in the flows for all basins, preserving the spatial correlation between the Poudre basin and the other modeled basins needed for the CBT model. The correlation will be maintained by sampling the same observed month for all basins when building the synthetic traces. For example, if we sampled October 1963 as one month in the Poudre basin while building a trace, we would build the traces for the other basins simultaneously using October 1963 for that month. The historical distribution of P and T across the basins during that month will therefore be embedded in the synthetic trace.

2.2 Step 2 – Apply Climate Change Adjustments

Using the bottom-up approach to explore system vulnerabilities to climate change, RTI will define a domain of potential changes of average precipitation and temperature. The 100 traces generated in Step 1 will be used as a baseline to compare against the same traces adjusted for climate change. The future domain will be explored by scaling P and T values by different amounts. RTI will create a set of hydrology traces to represent combinations of changes in P and T.

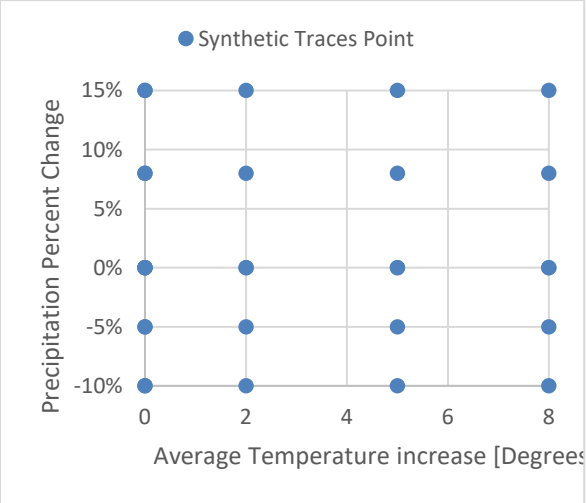

Figure 2 – Grid of Precipitation Change and Temperature increase to Develop Synthetic Hydrologic Traces

A grid of change values will be used to map vulnerabilities, with precipitation changes on one axis and temperature increases on the other. Precipitation changes will range from -10% (relative to current conditions) to +15%. Temperature changes will range from 0 °C to 8 °C above current temperatures. Figure 2 shows the grid with points at the combination of P and T for which synthetic hydrologic traces will be developed. The points in Figure 2 cover the entire domain but increase the detail in regions of the domain initially considered more important for the Vulnerability Study. All 100 traces will be adjusted for each grid point, leading to 1,900 climate change traces, in addition to the 100 baseline traces. These ranges are designed to be wide enough to include the GCM results from CMIP5 and hopefully future CMIP iterations. The National Climate Change Viewer from USGS indicates precipitation changes from -6% to +31%, and temperature increases from 0.6 °C to 4.9°C for the Poudre basin across the different GCMs for the 2050-2074 period (Alder and Hostetler, 2013). While some GCMs indicate that precipitation may increase more than 15%, we do not expect larger precipitation increases to be a source of vulnerability for Fort Collins Utilities.

Following a "bottom-up" approach by applying climate adjustments over a range, rather than matching specific GCM results, will allow a more thorough look at potential future conditions. The range of futures will be modeled and the futures that Fort Collins is vulnerable to can be identified. GCM-based future temperature and precipitation values can be plotted on top of the modeled ranges, to compare vulnerable futures against the futures projected by the GCMs. Figure 3 shows an example of the results of this bottom-up approach, with median vulnerability values for the 100 traces shown with interpolated colors (red to blue) in the T and P grid, and points representing the CMIP3 and CMIP5 GCM results of average change in T and P overlaid in green and purple.

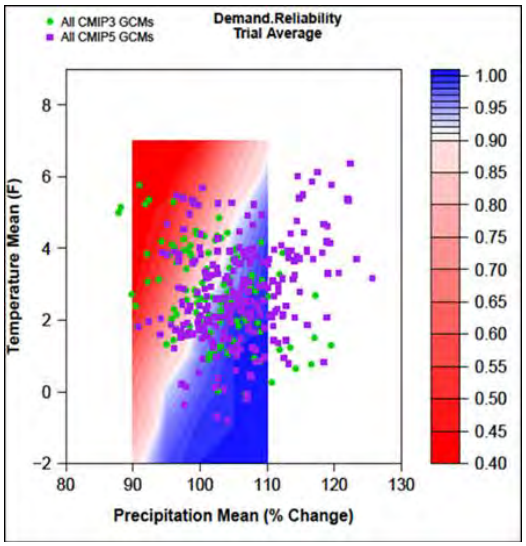

Figure 3. Example of bottom-up approach results
Source: Colorado Springs IWMP

The baseline traces will be adjusted for climate change uniformly. Temperature adjustments will be made by increasing every value in the time series by the adjustment amount. Precipitation adjustments will be made by scaling all values by the adjustment percentage.

While GCM results generally indicate that changes will vary between months, there is little consistency about the magnitude and timing of the variation among the different models (JFRCCVS, Figures 56 and 57). Choosing a single monthly distribution for changes may not accurately represent the true possibilities and running many different distributions would increase the complexity of the analysis for an uncertain benefit.

2.3 Step 3 – Run Hydrologic Models

RTI will use a set of calibrated hydrologic models to transform the baseline and climate-adjusted P and T into streamflow. These are the same models used in the JFRCCVS. Nothing in the models will be changed for this project, other than the precipitation and temperature inputs.

Recognizing that the model results do not perfectly represent reality in the simulated basins, RTI will apply bias-correction to the model output. The principles of the hydrologic models proposed tend to under-simulate large flows and over-simulate low flows. These tendencies are inherent to the modeling approach and cannot be fully eliminated through parameter changes. Quantile mapping is a procedure commonly used to reduce these biases (Gudmundsson et al. 2012). The distribution of the simulation results is adjusted to match the distribution of the observed streamflow. This step also reduces bias from any inaccuracy in the models. RTI will train the quantile mapping on the baseline case, and then use the same adjustments to correct all the results (baseline and climate-adjusted). This allows us to correct the model biases present in all runs while still allowing the results to simulate effects of climate change.

The JFRCCVS also adjusted potential evapotranspiration inputs when running these models to increase potential evapotranspiration (PET) for futures with higher temperatures. More recent research (Milly and Dunne, 2016) has shown that the adjustment procedure used significantly over-estimates the increase in PET. This is because using temperature increases to estimate PET increases

ignores other factors that limit PET, such as increased CO2 in the air reducing plant transpiration and vegetation changes due to the changed climate. Additionally, the JFRCCVS found that streamflow was not highly sensitive to PET increases. The ET is generally supply-limited, meaning soil moisture available for evaporating is less than the PET demand, and increasing the PET demand does not increase actual ET unless more soil moisture is available. Based on these factors, no PET adjustments will be made for this study. Note that the PET discussed here is only for natural vegetation in the watershed, and does not apply to irrigated crops. Increased agricultural PET is less limited by natural supply, and its effects for this study will be analyzed in the basin demand sensitivity analysis modeling to be performed by FCU.

The initial plan was to only run the Poudre Basin models and then assume that changes would be correlated with changes in the basins needed for the CBT modeling (Upper Colorado, Big Thompson, Boulder and St. Vrain). RTI investigated the correlations in streamflow changes between these basins using JFRCCVS results and found that the results did not exhibit a very strong correlation. For consistency and to generate a more complete product, RTI plans to also run hydrology models for the CBT basins using the same procedure as for the Poudre (described above). The Poudre Basin is split into 4 modeled sub-basins above the canyon mouth. The Upper Colorado above Lake Granby, Willow Creek, and the Fraser River are modeled as one sub-basin each. The Big Thompson is modeled as 3 sub-basins above Loveland and the St. Vrain and Boulder Creek watersheds are modeled as 4 sub-basins. FCU and Northern authorized the additional 95 hours required for this additional hydrology modeling scope as documented separately (Additional Hydrologic Modeling Estimate TM, 2017).

2.4 Step 4 – Disaggregate Flows and Run Yield Models

The hydrologic models provide flow at the North Fork below Seaman Reservoir and at the Canyon Mouth in the Poudre River Basin. The PBN model requires monthly flow inputs at 11 locations, mostly at higher elevations within the basin. Previous work by Riverside Technology, Inc. and CDM developed spatially disaggregated flows for the Poudre Basin Common Technical Platform (CTP), based on the two lower gage points. That work provides monthly factors for each PBN input point that can be used to distribute the downstream flows. These factors will be applied to the hydrologic model output to calculate inflows to the PBN model. There are other time series in the PBN model that are tied to the base hydrology and considered important for the analysis, i.e., the excess precipitation and the native flows time series. These time series will be re-sequenced based on the closest simulated flow to the base hydrology total flow at the two gages. The PBN model inputs will be organized in the central database for each trace resulting from the previous steps.

The CBT Model is a spreadsheet model that takes annual flows from the different CBT project sources and watersheds affecting other CBT allottee water supplies and estimates the annual quota that would be adopted by the Northern Board under those conditions. Northern will modify the CBT Model to incorporate inputs from the hydrologic models described above, and RTI will summarize and catalog the results from the hydrologic models into the central database developed for the Vulnerability Study. These results will be used by the FCU modeling system in conjunction with the CBT model to estimate an annual CBT quota for the PBN and the FCU system models. Baseline and climate-adjusted flows will be run through the models and cataloged in the central database using the functionality in the data management system (RTI and Stantec 2017) to be used in the Vulnerability Study.

FCU is investigating the changes in system yield for Fort Collins due to potential changes in future agricultural demands, assuming the higher temperatures will drive longer growing seasons with different water requirements within the constraints of the existing water rights. Also, FCU is investigating the effect of lower South Platte demands on the system yield for Fort Collins. The results of that analysis affecting the Vulnerability Study will be reflected in the final modeling approach.

3 Budget and Schedule Considerations

The proposed approach for the hydrologic modeling can be performed within the approved budget for Task 5 (including the CBT basins hydrologic modeling. The proposed activities can be performed within the original schedule (from December 2017 to February 2018) assuming no changes will be performed to the PBN model.

1 Introduction

This technical memorandum describes the development of the hydrology dataset developed for use in the Fort Collins Water Vulnerability Study. Hydrologic inputs required for the Vulnerability Study include time series for streamflows, water diversions, and other parameters that may contain greater variability than the historical record and reflect potential effects of future climate change and basin operations.

2 Hydrology Data Development

The hydrology development methods presented in this section were applied to the basins that must be analyzed and simulated to determine the water availability for the FCU system model, which is generated using the Poudre Basin Network (PBN) model and the Colorado-Big Thompson Quota (CBTQ) model. The basins included in the analysis are: Poudre River basin, Big Thompson River basin, St. Vrain River basin, Boulder Creek basin, Fraser Creek basin, Willow Creek basin and Upper Colorado River basin. Figure 1 shows the locations of the river basins included in the hydrological analysis.

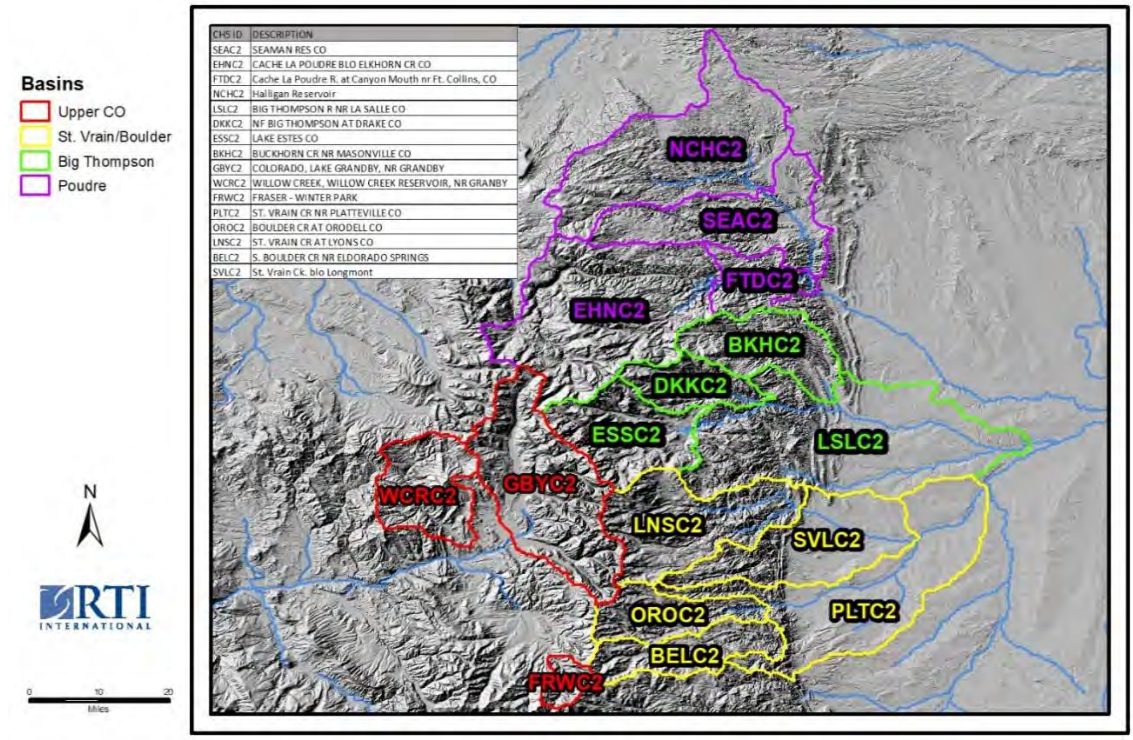

Figure 1 – Map Showing the River Basins included in the Hydrology Modeling for the FCU Vulnerability Study

The approach used to generate hydrologic inputs for the Vulnerability Study modeling is documented in the Hydrology Modeling Approach TM (RTI, 2018), which is key to understanding the presentation of results in this memo. The goal of the hydrology development approach is to generate synthetic sets of potential future hydrological inputs that include variability and large-scale shifts in precipitation and temperature trends due to climate change. The approach is based on the following steps:

- Weather Generation
  - Generate an ensemble of 100 precipitation and temperature traces for use in hydrologic simulations, each being 86 years long, which corresponds to the Fort Collins System model simulation period.
  - For each trace in the ensemble of reconstructed flow records, classify historical years as wet or dry.
  - Identify 100 sets of transition probabilities between wet and dry years based on 100 sub-sets of 86-year samples from the reconstructed record.
  - Construct 100 sequences of year type based on the 100 sets of transition probabilities.
  - Construct 100 synthetic precipitation and temperature traces by sampling entire months from the actual historical record according to year type, based on the 100 sequences of year type.
- Hydrological Modeling
  - Baseline: Generate streamflow traces from each of the 100 precipitation and temperature traces, using the Joint Front Range Climate Change Vulnerability Study (JFRCCVS) hydrologic models.

  - Climate Adjusted: Generate 18 sets of climate-adjusted streamflow traces based on various combinations of temperature and precipitation adjustments from historical conditions.
- Select representative traces for preliminary modeling.
- Pre-process inputs to the PBN model for use in yield modeling.

The following sections summarize the results of the hydrology development and processing to be used in the FCU Vulnerability Study.

2.1 Weather Generation (Ensembles)

Each year in the record of reconstructed flows for the Cache la Poudre River (the "Poudre") at Canyon Mouth (Woodhouse, 2006) was classified either as a wet or a dry year. This distinction was based on the median annual flow of the reconstructed data. The median of the reconstructed data from 1615-1999 was 286,712 AF. Figure 2 shows the plot of reconstructed annual flows in the Poudre River (blue) with the mean of observed flows (red). Annual flows greater than this threshold were considered "wet" and flows less than the threshold were classified as "dry."

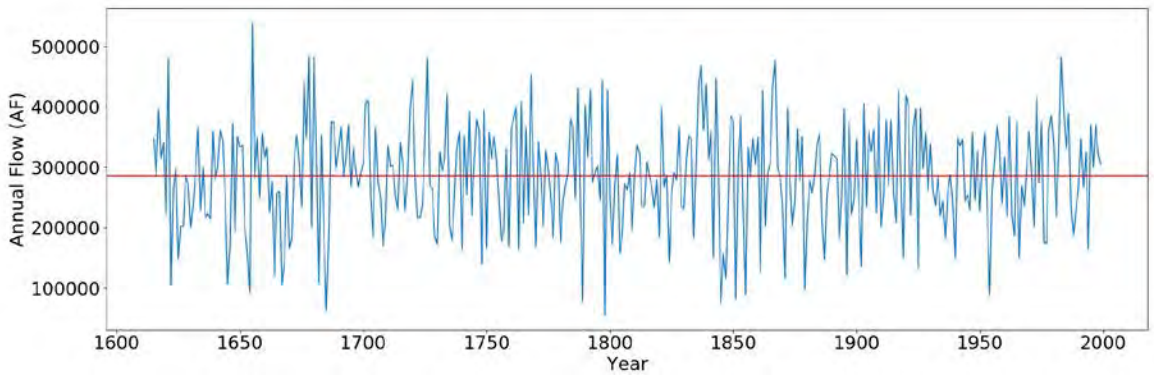

Figure 2 - Plot showing reconstructed annual flows at Canyon Mouth, 1615-1999, in acre-feet (blue) with the mean of observed flows (red).

RTI used a sampling procedure based on the exceedance of dry to wet transition probabilities from rolling windows over the reconstructed period to generate 100 traces that use statistics from a range of wet and dry periods. The selected period for the traces (and the rolling windows) is 86 years that agrees with the current Fort Collins planning model simulation period. The center-half of the selected period was used to calculate the transition probabilities of each window, excluding from the calculation the initial 21 years and the last 22 years of each window to add randomness to the transitional probabilities. Figure 3 illustrates the rolling window concept, showing the first 86-year window (gray) with the 43-year center-half window (orange). For the period of reconstructed values, 1615-1999, we use the center-half windows of 43 years to represent the 86-year windows, with the first center-half window starting in 1636 and the last center-half windows ending in 1977. For each 86-year rolling window, we assigned the center-half window probability of a dry year being followed by a wet year as the representative probability for the rolling window.

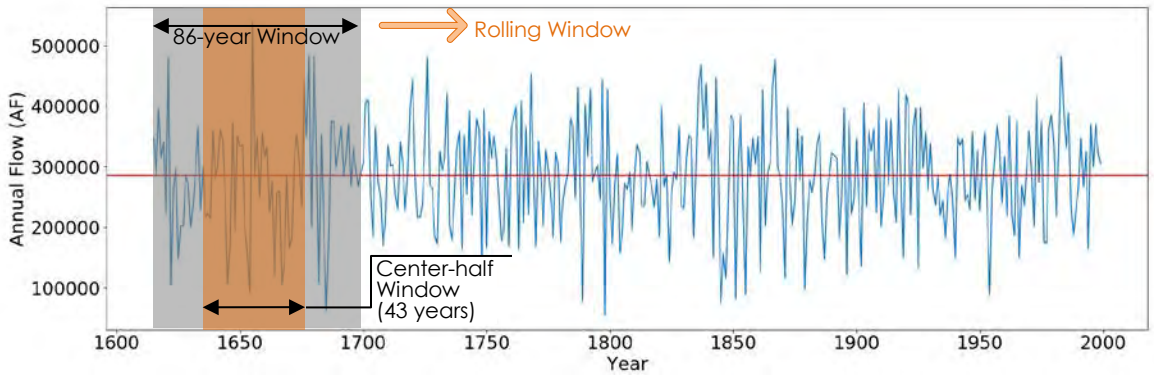

Figure 3 - Diagram showing the rolling 86-year window with the center-half window (yellow) used to calculate the probabilities of dry years being followed by wet years.

The dry-to-wet transition probability, written below as $P(D \rightarrow W)$, is defined by the following equation.

$$P(D \rightarrow W) = \frac{\text{No. of dry years followed by a wet year}}{\text{Total no. of dry years}}$$

The distribution of dry-to-wet transition probabilities in the center-half windows for the reconstructed period is shown in Figure 4.

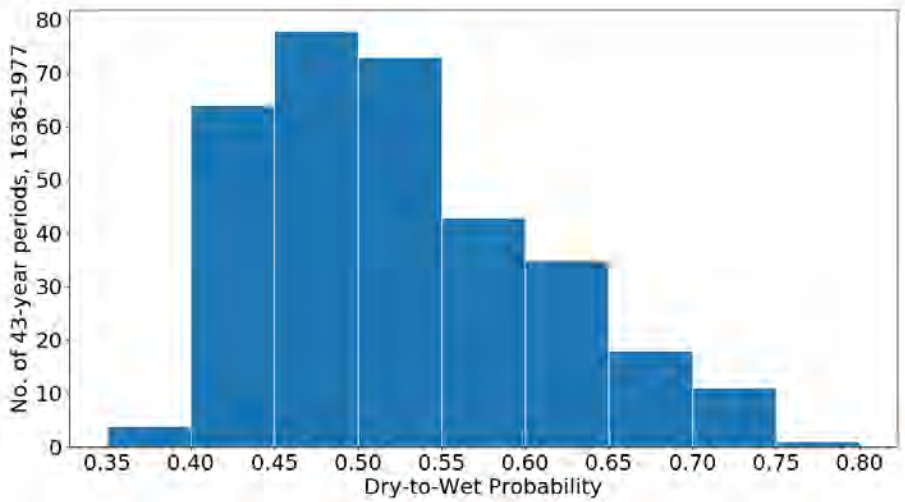

Figure 4 - Histogram showing the distribution of dry-to-wet probabilities for the rolling center-half windows for the reconstructed period

The dry-to-wet probability values representative for all the center-half rolling windows ranged from 0.38 to 0.78. Figure 5 shows the exceedance curve of the dry-to-wet probabilities for all the rolling windows.

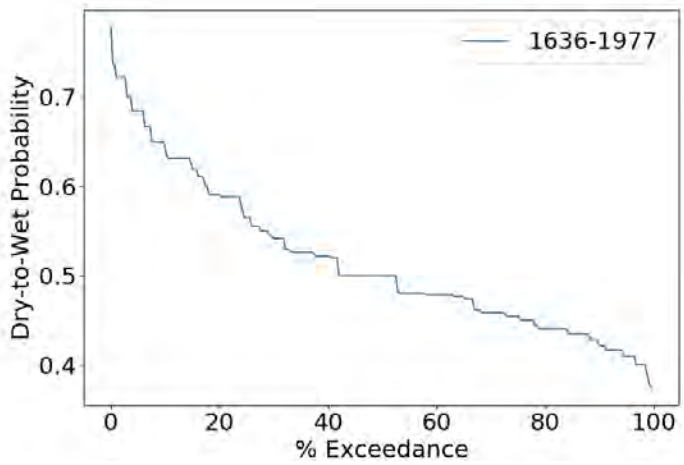

Figure 5 - Plot showing the exceedance curve of dry-to-wet probabilities calculated from the rolling 43-year periods

We performed the selection of 100 rolling windows using the exceedance curve, finding the rolling window that had a representative dry-to-wet transition probability closest to one for each percentage value in the dry-to-wet exceedance curve from 1 to 100 percent. The rolling windows were selected based on the representative transitions probability (center-half windows), but the transition probability matrix for generating the hydrological traces was computed using the 86-year rolling windows to capture in the statistics the random occurrences around the center-half window. Each of the resulting 86-year periods were analyzed to compute four transition probabilities: 1.) probability of a dry year followed by a dry year, 2.) probability of a dry year followed by a wet year, 3.) probability of a wet year followed by a dry year, and 4.) probability of a wet year followed by a wet year. Figure 6 shows a diagram of the four transition probabilities following the transition from the current state to the future state.

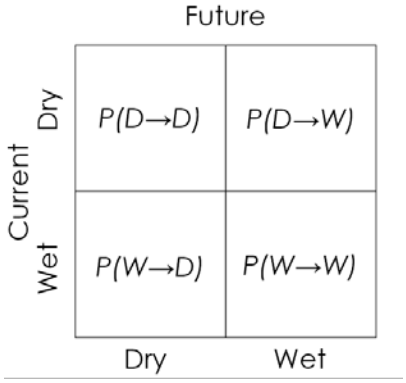

Figure 6 - Diagram showing the breakdown of the transition probability matrix.

For example, for an exceedance probability of 75%, we selected the window having the closest dry-to-wet exceedance value (75.08%) in Figure 5, which is identified with year 1850 that correspond to the first year of the center-half window. Figure 7 shows the 86-year window corresponding to the year 1850. The corresponding dry-to-wet transition probability for the center-half 43-year window is

0.45. The transition probabilities to generate this trace were then calculated using the 86-year window, 1829 to 1915, which resulted in a new dry-to-wet transition probability of 0.52, when including the years before and after the center-half window. The procedure in this example was completed for each percent of the exceedance curve.

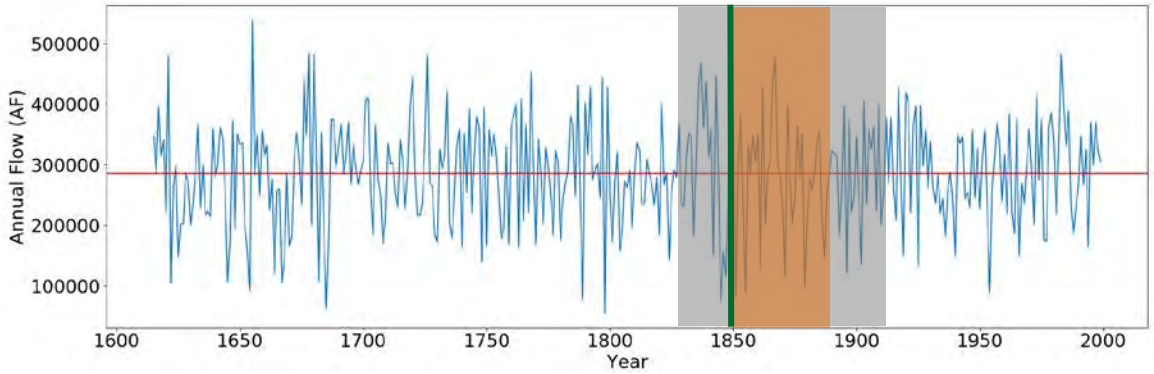

Figure 7 - The 86 years (gray shade) surrounding the year 1850 (green line) were used to calculate transition probabilities for a 75% exceedance. The 43-year period that contributed to the exceedance curve is shown in orange.

The 86-year window transition probabilities for the years corresponding to the 1 percent and 99 percent of the dry-to-wet exceedance curve in Figure 5 are shown in Table 1 and Table 2.

Table 1- Transition probabilities from the lower end of the exceedance curve (year 1737)

P(D→D) **0.45**	P(D→W) **0.55**
P(W→D) **0.53**	P(W→W) **0.47**

Table 2- Transition probabilities from the upper end of the exceedance curve (year 1649)

P(D→D) **0.43**	P(D→W) **0.57**
P(W→D) **0.56**	P(W→W) **0.44**

Historical years with 6-hour observed precipitation and temperature were classified as wet and dry years based on the historical flow at the Poudre River at Canyon mouth, using the median of the

reconstructed flow as the classification threshold. Years with annual flow above the threshold were classified as "wet" and years below were classified as "dry." The result was a bin of dry years, and a bin of wet years.

Each of the 100 sets of the annual transition probabilities was then used to randomly generate a sequence of 86 wet and dry years. The result of this process was 100 binary wet/dry sequences of 86 years each. Then, we used each of the binary sequences to engineer an 86-year long synthetic precipitation and temperature trace with 6-hour temporal resolution. For each of the year types in the sequence, we randomly pulled each of the 12 months of precipitation and temperature data (i.e., month-long chunks) from a historical year in the corresponding wet or dry year bins. Note that each month of the engineered series could potentially come from a different year with the corresponding wet/dry classification. For example, when the binary sequence called for a dry year, the January precipitation data was randomly selected from the pool of "Januarys from Dry Years." The same procedure was followed to select precipitation data for February to December for this dry year. The process continued with the next year type of the sequence, sampling months for that year type as described above. As a result, each synthetic precipitation year was composed of twelve month-long chunks originating from potentially different years, which were either all dry, or all wet.

The 100 synthetic 86-year time series of precipitation and temperature generated using this process were imported into dashboards to be visualized and compared. HydrologyDataset_042218.twbx contains the precipitation series summarized per month and the file HydrologyDataset_042218_TEMP.twbx is used to present the corresponding temperature generated series.

2.2 Baseline Hydrological Modeling

The hydrologic models from the JFRCCVS were used to generate streamflow traces for locations contributing to Fort Collins' water supply based on the precipitation and temperature traces described in the previous section. Both the synthetic precipitation and temperature traces and the historical precipitation and temperature data were used in this hydrology dataset. The historical inputs were designated as trace 0. The models were run using the National Weather Service River Forecast System and incorporate the SNOW-17 snow accumulation and melt model and the Sacramento Soil Moisture Accounting Model to calculate natural (unregulated) streamflow. The 16 sub-basins shown in Figure 1 were all modeled as part of this hydrology dataset. The models run at a 6-hour timestep and lag and K routing is used to route flow between sub-basins. The simulation period for the planning model is 86 years and agrees with the length of the synthetic traces. The hydrologic models were setup for 86-year simulation, arbitrarily starting in WY1939 and ending in WY2024 to avoid model issues with dates later than 2030. The historical trace of reconstructed naturalized flows at the control points are shorter and span from WY1950 to WY2008.

The 6-hour time series streamflow results from the hydrologic models were processed and converted to monthly flow averages in cubic feet per second for use in the Fort Collins and Poudre Basin system simulation models, which operate on a monthly time step. The monthly time series were bias-corrected to reduce inherent model errors. The bias correction is designed to account for errors in the hydrologic models due to both calibration errors and bias built into the design of the model. The hydrologic models used for this work tend to underestimate high flows and overestimate very low

flows. There are also calibration errors throughout the distribution. Bias correction using the quantile-mapping method helps to reduce this bias. The Tableau dashboard (FlowMetricsV4.twbx) summarizes the streamflow results.

To perform bias correction, estimated monthly natural flow data was available from the JFRCCVS for 5 of the 16 sub-basins in this study: Cache la Poudre at Canyon Mouth (FTDC2), Big Thompson at Drake (DKKC2), St. Vrain Creek at Lyons (LNSC2), Boulder Creek at Orodell (OROC2) and Colorado River at Lake Granby (GBYC2). For each of these 5 locations, the observed natural flows and the simulated historical flows were used to correct all the simulated trace flows. The correction amount was set for each point on the distribution function to match the distribution of simulated historical flows to the distribution of observed natural flows. This creates a set of correction amounts (positive or negative) for the full range of the distribution. So the 10th percentile flows (which can be a different magnitude in the observed flows than in the simulated flows) have a specific correction amount, the 90th percentile flows have a different correction amount, and every other point in the distribution has a correction amount. This set of correction values associated with various percentiles is then applied to each of the 100 generated traces for that sub-basin, and each monthly value in all traces is corrected accordingly. Each sub-basin with observed flows has a separate set of correction values.

See Figure 8 for the model results for FTDC2, and see Figure 9 for an example of the bias correction results at the FTDC2 location with the observed and simulated exceedance curve used to derive the correction and the correction applied to the trace 1 results. In Figure 9, the left plot shows the distributions of the observed and simulated time series and the right plot shows the simulated and corrected curves of trace 1. The difference between the observed and the simulated at each point in the left graph is applied as a correction to the same point on the right graph. So at low flows (below ~90 cfs, 40th percentile), the simulated flows are over-estimated compared to the observed. The correction of the flows below the 40th percentile is therefore negative and the corrected time series is lower than the original for that range.

Table 3 shows statistics for the corrections for each station. The mean row represents the average correction amount over all months in the period of record. The max and min rows represent the largest and smallest corrections in any individual month.

For sub-basins upstream of a point with observed data, the correction amount was scaled down proportionally to the relationship between the flow of the upstream point and the point with observed data, for a given month. As an example, the uncorrected total flow in a given month at the Canyon Mouth may be 100 cfs, which is the 10th percentile flow for that trace. The uncorrected flow on the North Fork below Seaman Reservoir is 50 cfs for the same month and trace. If the 10th percentile correction amount for the Canyon Mouth is 2 cfs, the correction applied to the North Fork will be 1 cfs. In another month, the Canyon Mouth flow may be 200 cfs (15th percentile) with Seaman Reservoir still at 50 cfs. If the correction amount at that percentile is 3 cfs, the correction at Seaman Reservoir that month would be only 0.75 cfs.

The Canyon Mouth bias correction was used in this way to also correct the Cache la Poudre below Elkhorn Creek (EHNC2), Halligan Reservoir (NCHC2), and Seaman Reservoir (SEAC2) flows. The bias correction at Drake (DKKC2) was used to correct the Lake Estes sub-basin (ESSC2).

The remaining sub-basins that did not have observed data or downstream observed data were not corrected. Correcting these other points using upstream or adjacent basins would potentially distort

the results by forcing the flow distribution at the corrected point to match the flow distribution at the observed point. Even adjacent basins may have quite different distributions. Discussions during the project have indicated that the Poudre Basin is the most important to Fort Collins Utilities' water supply, followed by the Upper Colorado Basin. The entire Poudre Basin and the Colorado River above Lake Granby were bias corrected. The other uncorrected streamflow locations in the Big Thompson Basin, St. Vrain Basin, and Upper Colorado Basin watersheds are included in this analysis mostly for CBT allocation modeling and will not be used directly in the PBN model.

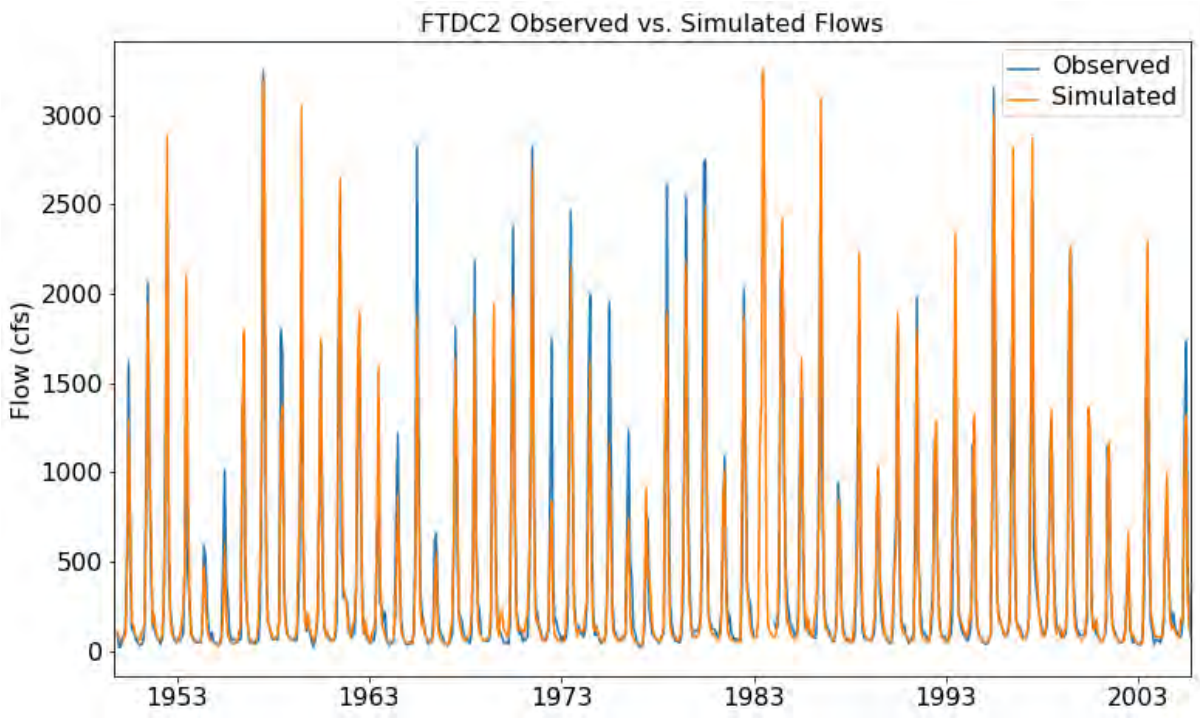

Figure 8 – Model Simulation Results for FTDC2

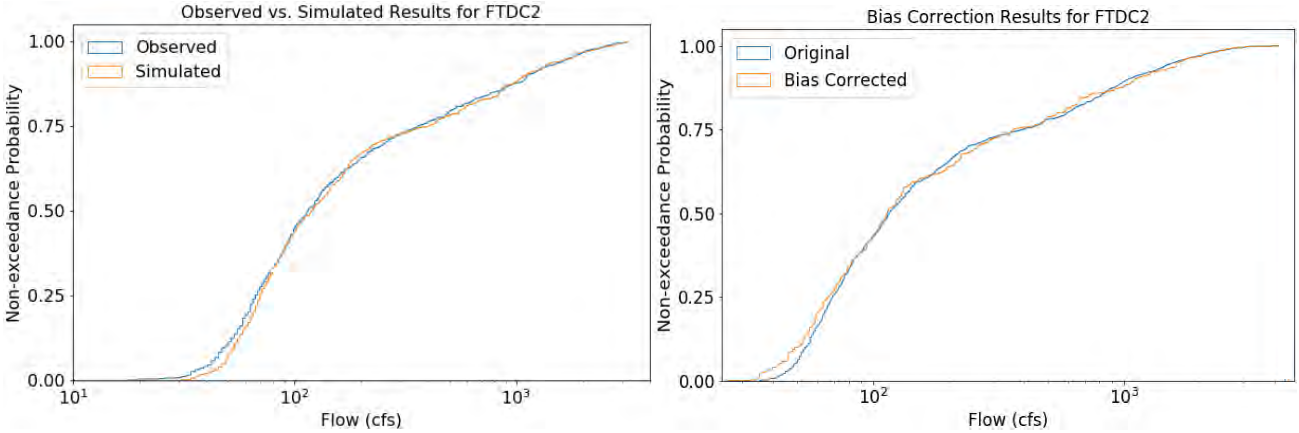

Figure 9 – Non-exceedance plots showing bias correction for FTDC2 (trace 0) and the result with bias-correction for trace 1.

Table 3 - Description of Corrections at Locations with Observed Flows

	FTDC2	DKKC2	LNSC2	OROC2	GBYC2	FRGC2
Mean correction (%)	-2.1	1.8	-2.5	4.1	-0.8	-7.1
Max correction (%)	11.6	74.0	15.3	44.9	23.1	9.4
Min correction (%)	-25.6	-28.0	-63.9	-36.9	-36.1	-17.8

2.3 Climate Adjusted Hydrological Modeling

In addition to the baseline modeling for all sub-basins and traces that is based on historical climate conditions, the climate scenarios defined in the Hydrologic Approach Technical Memo (RTI, 2018) were used to perturb inputs to the previously described hydrologic models to produce climate-adjusted streamflow traces. A climate scenario consists of a combination of temperature expressed as a deviation in °F from historical temperature conditions, and precipitation expressed as a deviation in percent from historical precipitation conditions. Figure 9 shows the selected scenarios in the Hydrologic Approach Technical Memo. Table 4 shows the names of the climate scenarios and their corresponding adjustment of temperature and precipitation.

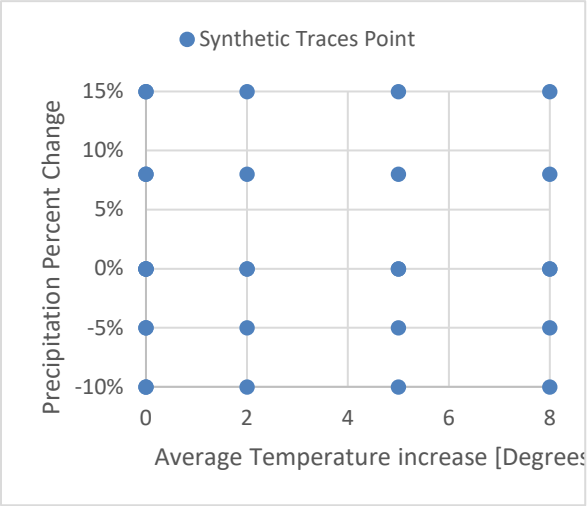

Figure 10 – Grid of Precipitation Change and Temperature increase to Develop Synthetic Hydrologic Traces

Table 4 – Climate Scenario Name and Definition

Scenario Number	Name	ΔT [°F]	ΔP [%]
1	Base	0	0
2	CC:T0P0	0	0
3	CC:T2P0	2	0
4	CC:T5P0	5	0
5	CC:T8P0	8	0
6	CC:T0P-10	0	-10
7	CC:T2P-10	2	-10
8	CC:T5P-10	5	-10
9	CC:T8P-10	8	-10
10	CC:T0P-5	0	-5
11	CC:T2P-5	2	-5
12	CC:T5P-5	5	-5
13	CC:T8P-5	8	-5
14	CC:T0P7	0	7
15	CC:T2P7	2	7
16	CC:T5P7	5	7
17	CC:T8P7	8	7
18	CC:T0P15	0	15
19	CC:T2P15	2	15
20	CC:T5P15	5	15
21	CC:T8P15	8	15

Precipitation and temperature adjustments were defined for each scenario in the Hydrologic Approach Technical Memo, and the hydrologic model inputs were adjusted accordingly. For example, scenario 15 is defined as a 2 °F temperature increase and 7% precipitation increase. To run scenario 15, the input temperatures for all sub-basins and traces were increased by 2 °F compared to the baseline for all timesteps in the simulated period. The input precipitation values were all increased by 7% for all timesteps. These changes were made by scripts that adjust the hydrologic model input files at run time, without having to create new input files.

The results from the climate adjusted hydrologic model runs were saved and processed the same way as the baseline results, including bias-correction. Figure 11 shows example monthly results for the Canyon Mouth gage, trace 1. Three climate scenarios are shown in addition to the baseline results. The scenarios all show earlier runoff due to temperature increases, and the volume of runoff

depends on the change in the precipitation as well as the temperature. See the Tableau dashboard for further exploration of these results.

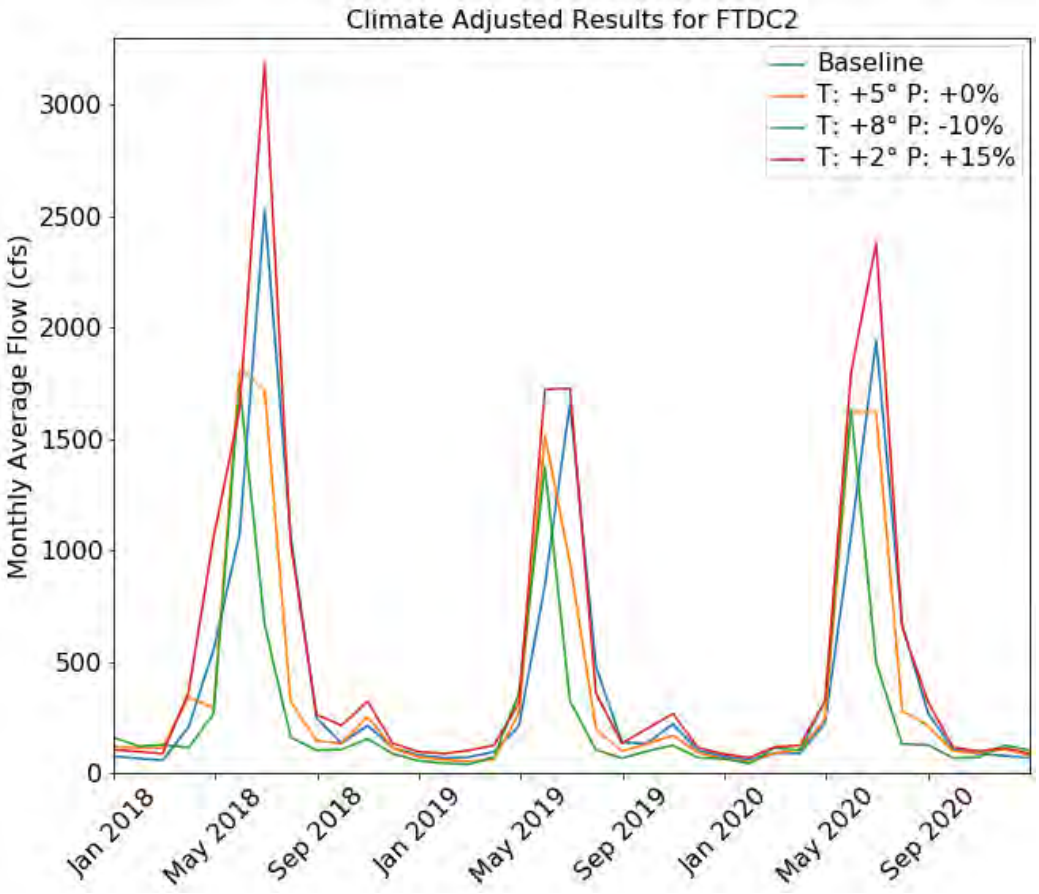

Figure 11 – Climate adjusted results example for FTDC2, trace 1.

2.4 Selection of Representative Traces

For the initial modeling of the impact of various risks in the Vulnerability Study, only 5 or 6 of the 100 traces will be used to allow more detailed analysis and initial exploration of vulnerabilities and system performance. This section describes the method used to select those representative traces.

A procedure and a selection tool were developed through discussions with Fort Collins Utilities to choose traces for this detailed modeling. A set of 24 metrics or statistical measures was developed for application to each baseline trace (Scenario 1) simulated streamflow that help describe the overall hydrologic characteristics of the traces, particularly the dry periods. The streamflow metrics include overall average value, minimum value, minimum of 3, 5, and 10-year moving averages, and resiliency among others. Based on input from FCU, a few of the metrics were selected as being the most relevant and useful for describing key hydrologic parameters of interest for selecting traces for the Vulnerability Study. Table 5 includes the definition of the metrics used in the selection of representative traces.

Table 5 – Definitions of Streamflow Trace Performance Metrics Selected for Analysis

Metric	Narrative
MovingAvg3_Min	Minimum three-period moving average of the average annual flows
MovingAvg5_Min	Minimum 5-period moving average of the average annual flows
MovingAvg10_Min	Minimum 10-period moving average of the average annual flows
Dry to Wet Probability (Resilience measure)	Number of months below the threshold (i.e., median flow) followed by a period above the threshold, divided by number of periods below the threshold
Average Dry Flows (Vulnerability measure)	Average of the values below the threshold (i.e., median flow) using periods below the threshold as a fraction of the threshold. For example, a value of 0.5 indicates that the average value when the value is below the threshold is 50% of the threshold.

An Excel-based selection tool[1] was developed that can be used to rank the traces from driest to wettest by weighting the different metrics according to user preferences. Each metric is given a score with a user-assigned weight and can be used in the ranking. For each metric a trace rank is calculated based on its position with respect to the extreme (i.e., drier or wetter) expected value. The score for each trace is computed multiplying the rank by the user selected metric weight and summing the weighted ranks for all the metrics. The traces are then sorted according to their total score and the top 10 are displayed. Scores from multiple basins and the 16 modeled points for a trace can be combined using weights for the selection of the top 10.

In discussion with Fort Collins Utilities the metrics used to select the representative hydrologic traces are the minimum value of the 3- and 10-year running average, resilience, and vulnerability. Metrics were all given an equal weight in the selection process. Resilience is defined here as the probability of having a wet year following a dry year, and vulnerability is the average of the annual streamflows in all the years with annual flow below the median annual flow. Two key locations were selected for the analysis of representative traces: the Cache la Poudre at Canyon Mouth and Colorado River above Lake Granby locations. These were used with equal weights.

The representative traces were selected based on the frequency that they ranked in the top 10 on the following analyses:

(1) Considering one metric and basin at a time, the top 10 traces in each case (i.e., the traces that had the highest metric scores, for example the lowest minimum 3-year running average annual streamflow) were compiled for the selection process. The results include 8 sets of 10 traces from all the metric/basin combinations (i.e., 4 metrics and 2 basins).

(2) The 4 metrics for each basin individually and the 4 metrics with the 2 basins were all equally weighted and used to select three additional sets of top10 traces that had a high rank when those factors were considered simultaneously.

Table 6 shows the top 10 traces for the 11 sets that resulted from the previous analysis and were used in the selection. From the 11 sets of top 10 traces, the traces that were present in the top 10

[1] File name: Trace MCDA v4.xlsx

most often were selected as the representative traces. An additional representative trace was the 50th ranked trace (i.e., median trace) with the 4 metrics and the 2 basins considered simultaneously and having equal weighting. The six traces chosen as the representative traces for use in the detailed risk assessment modeling are: **15**, **63**, **95**, **47**, **67** and **52**. Traces 15, 63, and 95 were present in the top 10 for many of the metrics and represent 3 of the top 4 traces when all metrics and basins are included at the same time. The other trace in the top 4 is 84, which has its driest period at the end of the trace, making it difficult to see the effects in the modeling results. Instead, trace 67 was selected, which appears in the top results several times and has an extended dry period in the middle of the record. Trace 47 appears in the top 10 only three times but is the driest trace at the Canyon Mouth when considering the 10-year average, which should make it a good trace for analysis. Finally, the trace ranked 50th out of 100 using all the metrics and both basins is 52.

Table 6 – Top 10 Traces for each of the Analyses used to Select the Representative Traces

Set	1	2	3	4	5	6	7	8	9	10	11

2.5 PBN Input Preparation

The hydrology results described above capture more natural variability and more climate effects than the historical observed streamflow record, and thus represent sets of different potential conditions in the basin. The simulated naturalized flows are the source of the hydrology inputs for the PBN model. Several PBN model inputs in addition to the naturalized streamflows are also associated with the hydrology of the base existing conditions model. These model inputs were determined in the current model using the historical record of basin streamflows, diversions, and other observed or calibrated data. Because there was no straightforward way to adjust all the model inputs for the new variability introduced by the resequenced historical hydrology and the climate-adjusted hydrology, Fort Collins Utilities performed sensitivity analyses to determine the effect of those time series on the Fort Collins simulated yield. These analyses were used to select the method of handling those inputs in the generation of the hydrology input datasets for the PBN model for the Vulnerability Study. This section describes the hydrologic time series processing methods implemented for simulating future conditions in the PBN model.

2.5.1 Disaggregate Flows

The naturalized streamflows generated in earlier steps were used to compute annual streamflows at 11 inflow points for the PBN model that represent the upstream water availability for the different hydrology sets. RTI used the method developed for the Common Technical Platform (CTP), which is the modeling platform used for the Halligan Reservoir Enlargement EIS and Northern Integrated Supply Project EIS. It uses naturalized flows for the Canyon Mouth (FTDC2) and North Fork (SEAC2) gauges and a set of monthly factors to estimate the PBN inflows as a function of the naturalized flows at FTDC2 and SEAC2. The monthly factors for all the PBN inputs are shown in Table 7. To create each PBN monthly streamflow input the FTDC2 and SEAC2 flow was multiplied by the appropriate fraction for each month in the record.

Table 7 – Disaggregation Flow Factors for the PBN Inputs

The PBN hydrologic input time series computed for all the traces were imported into the database and cataloged based on the climate change scenario and the trace number. The scenario names and IDs used to catalog the hydrology results into the database are shown in Table 4.

2.5.2 Other Time Series Inputs

It was identified that several input datasets, in addition to the disaggregated natural flow nodes described in section 2.5.1, would need to be developed in preparation for the modeling efforts of different hydrological scenarios for the Vulnerability Study. FCU staff performed several sensitivity analyses to help determine what method and level of effort should be used to develop the input datasets. The modeling constructs that were associated with the hydrology state and a function of the future conditions are:

- agricultural demands in the basin
- the downstream end of the network of water users in the South Platte River below the Kersey gage, referred as the "fish bone"
- excess precipitation construct, and
- trans-basin diversions

The following sections describe each of these sensitivity analyses and the resulting strategy for adjusting existing condition PBN inputs to reflect different future hydrologic conditions.

2.5.2.1 Sensitivity to Increasing Agricultural Demands in the Basin

PBN modeling simulations require input data for agricultural water demands in the Poudre Basin. There was a concern that increased agricultural demands under certain climate change scenarios could significantly decrease yields of FCU water supplies. FCU staff performed a sensitivity analysis to determine if FCU water supplies are sensitive to increased agricultural water demands in the Poudre Basin to help inform how to develop input data for future modeling simulations.

The sensitivity analysis effectively simulated an extended irrigation season and increased water demand during the irrigation season by approximately 10% per year to see if the increased demands impact FCU water supplies. The results of the analysis showed little decrease (less than 1% reduction in the Storage Reserve Factor) in the yields of FCU supplies. FCU staff determined that this minor impact did not warrant extensive effort to develop adjusted agricultural input data to represent different hydrologic conditions for future modeling scenarios. The base agricultural demands will be re-sequenced to account for water use in wet and dry periods for different hydrologic conditions.

2.5.2.2 Sensitivity to Increasing Demands from Other South Platte Basin Water Users

PBN modeling simulations also require input data which represents demands from other water users in the South Platte basin. There was a concern that increased South Platte demands under certain climate change scenarios could significantly decrease yields of FCU water supplies. FCU staff performed a sensitivity analysis to determine if FCU water supplies are sensitive to increased Poudre basin water demands from water users in the South Platte to help inform how to develop input data for future modeling simulations.

This analysis reduced available supplies in the South Platte basin by approximately 10% per year, thus forcing demands in the basin to seek water supplies further upstream in the Poudre Basin. The results of the analysis showed little decrease (less than 1% reduction in the Storage Reserve Factor) in the yields of FCU supplies. FCU staff determined that this minor impact did not warrant extensive effort developing adjusted input data to represent future water use by other South Platte water users for future modeling scenarios.

2.5.2.3 Excess Precipitation Construct

One PBN construct that is also tied to the hydrological regime consists of a demand node which represents native vegetation's water demand (NATIVE) and a supply node that represents the excess precipitation on croplands that is not removed from the system by evapotranspiration

(PRECIP). These nodes are part of a PBN construct that represents groundwater inputs and interactions to the Poudre River that are used to support calibration of basin inflows and operations with gaged flows along the river. There was a concern that changes in the NATIVE and PRECIP values under certain climate change scenarios could significantly decrease yields of FCU water supplies. FCU staff performed two sensitivity analyses to help determine if FCU water supplies are sensitive to changes in the NATIVE and PRECIP node inputs to help inform how to populate the nodes in future modeling scenarios.

The first sensitivity analysis populated the nodes with re-sequenced input data using one of the wet-dry year sequences developed for the alternate hydrology based on the paleo-derived transition probabilities. The second sensitivity analysis used monthly averaged input data from the existing model period of record for time series of the NATIVE and PRECIP model nodes. Both analyses resulted in notable changes to the yields of FCU water supplies and had consequential impacts to the Storage Reserve Factor in the modeling simulations. FCU staff and RTI explored correlations between other factors and these nodes but did not find any strong correlations. Although there are notable changes to FCU water supply yields, FCU staff understands that in the original development of the PBN these nodes and associated constructs were populated using '*like-year*' values from historical periods for synthetic modeling periods. This method uses time series values from the historical period to represent time series of future conditions based on similarities of flows at selected locations. Given its use in prior FCU modeling efforts, it would be reasonable to use like-year values from historical data for future hydrological scenarios for the Vulnerability Study.

2.5.2.4 Trans-basin Diversions

The FCU trans-basin imports from the Upper Colorado River basin into the Poudre River basin are simulated as inflow time series in the PBN model. These inflows are based on the historical diversions, which were determined by the system operators based on different factors, including water rights, availability of water in the diverting basin, storage availability and operations in the receiving basin, diversion capacities, repairs and maintenance schedules. Trans-basin diversions are a significant component (nearly 15% of the average native flows in the basin) of the FCU yield on an annual basis and are the drivers of the FCU's Reuse Plan; therefore, it is important to determine appropriate trans-basin diversion time series for modeling of future conditions.

An extensive analysis was performed to attempt to correlate the historical trans-basin diversions with naturalized flows at stream gages in both East Slope and West Slope basins. Correlations were investigated using monthly flows, annual flows, seasonally segregated flows, and other methods to attempt to find an approach for estimating historical trans-basin diversions from historical naturalized streamflows. Unfortunately, none of the analyses showed strong correlations between those variables. Based on this outcome, FCU staff recommended adopting the like-year approach to estimate trans-basin diversions, since this method was used to develop input data for sites without measured diversions in the previous versions of the PBN.

2.5.2.5 Recommended Like-Year Modeling Approach

The sensitivity analyses for the excess precipitation construct and the trans-basin diversions showed that impacts on the FCU yield could be significant. Therefore, it is necessary to implement an approach for representing those inputs synchronized with the future hydrological conditions to be simulated for the Vulnerability Study. An approach based on the *like-year*, used in previous PBN

analyses, is recommended to estimate these PBN input time series for future conditions. Although the results of the agricultural demand sensitivity analysis and the South Platte water users' sensitivity analysis suggest these inputs have little impact on FCU water supplies, for consistency, it is recommended to use a *like-year* approach for these time series as well to simulate future conditions.

The *like-year* approach determines values for the new time series based on values from a historical year with the most similar total annual flows at key locations. For example, if simulated year N has an annual streamflow for the Cache la Poudre River at Canyon Mouth of 25,100 acre-feet, the PBN input data from the historical year with the annual streamflow at the Canyon Mouth closest to 25,100 acre-feet would be used to populate the time series for simulated year N. For trans-basin diversions the conditions in both the Poudre River basin and the Colorado River basin are drivers of the diversion, so the recommended *like-year* approach was based on the sum of flows at the Cache la Poudre River at Canyon Mouth and the Colorado River at Granby Lake to select the historical year to represent the future conditions. That selected historical year was used to create the time series for all the PBN input datasets. This method adjusts PBN inputs to be consistent with the magnitude of flows for future conditions, according to the reduction/increase in simulated naturalized flow compared to historical conditions. Using the same like-year for all the input time series populated using the like-year approach preserves the relationships between the East Slope and West Slope operations captured in the historical data. For the selected alike year, the historical monthly time series were used for creating the synthetic time series of the PBN inputs. Table 8 shows the list of PBN names that are processed with the like-year approach.

2.6 Tools for Yield Modeling

RTI catalogued the hydrology sets into the FCU modeling system database and built tools to process inputs for the PBN model based on the future conditions and the time series generation recommended approach. The hydrology sets cataloged for the Vulnerability Study are composed of (1) the inputs to the PBN model, estimated from the simulated naturalized flow inputs, and (2) the naturalized flows simulated at the key locations.

RTI developed a tool to calculate the PBN inputs for the different hydrological scenarios that extracts the current time series in the PBN model (i.e., historical) to the database and resequences the time series to create PBN inputs for each alternate hydrology. The processed time series are written into the MODSIM version 7 ADA format to be imported into the PBN model at run time using the new modeling system functionality.

Water Vulnerability Study

Technical Memorandum

Scenarios for Vulnerability Analysis

Date: January 2, 2019 (Revised 01/25/2019)
From: Chip Paulson, Lisa Fardal, Neil Stewart
To: Fort Collins Utilities

Stantec

1.0 INTRODUCTION

As part of the City of Fort Collins Utilities (Utilities) Water Supply Vulnerability Study (Study), potential risks and uncertainties to both the Utilities water supply system and the Colorado-Big Thompson (C-BT) project, operated by the Northern Colorado Water Conservancy District (Northern Water), were identified, scored, and prioritized. These identified and prioritized risks and uncertainties are summarized in the *Risk Identification Technical Memorandum* (TM).

To quantify the impacts of these risks and uncertainties to the performance of Utilities' water supply system, baseline conditions for future scenarios were established in the three simulation models used in the Study. "Baseline conditions" consist of existing or currently planned water resources infrastructure and water rights portfolio, and existing operations. Next, the prioritized risks and uncertainties were assembled into scenarios that capture a variety of potentially impactful futures. These scenarios will be simulated in the three models and their performance will be compared to baseline conditions, quantifying their impact to the water supply system. This will help inform Utilities on which future conditions create significant vulnerabilities for their water supply system.

This TM presents the baseline assumptions for the three models used for the Study and the future conditions scenarios that will be simulated in them.

2.0 BASELINE ASSUMPTIONS

As noted above, baseline conditions are a future system state with existing or planned infrastructure, a portfolio of existing or planned water rights, and existing operations and policies surrounding water deliveries. Baseline conditions represent the conditions against which vulnerability impacts and, in later studies, proposed system improvements would be compared. Assumptions for baseline conditions were established in the three models included in the Study: the C-BT Quota Model, the Poudre Basin Network (PBN) Model, and the Fort Collins System Model (FC System Model). The baseline conditions across all three models do not include any identified risks or climate altered hydrology and are intended to represent the most reasonable future for planning purposes. Results of water supply system performance under the baseline conditions will be used to assess the impact of the selected scenarios and the vulnerability of the Fort Collins water system.

2.1 C-BT QUOTA MODEL

The C-BT Quota Model, developed and maintained by Northern Water, has several input controls for simulation in the model. This section presents the baseline settings for those input controls, organized similarly to how they are presented in the C-BT Quota model. All risks under "Simulation Settings" are off. These settings were set based on discussions between Northern Water and Fort Collins Utilities' staff.

- **Table 2.1** shows the baseline settings for initial storage contents, assuming Chimney Hollow is operational.
- **Table 2.2** shows the baseline settings for the C-BT municipal and industrial (M&I) and agricultural ownership controls
- **Table 2.3** shows the baseline settings for the Windy Gap controls
- **Table 2.4** shows the baseline settings for the additional controls

Table 2.1 - Initial Storage Contents in CBT Quota Model

Storage Item Name	Starting Value (acre-feet)
Lake Granby, Horsetooth and Carter Lake (LG+HT+CL) Beginning of Year (BOY) Active Contents	550,000
M&I C-BT Carryover Storage	20,000
Agricultural C-BT Carryover Storage	0
Windy Gap Storage in Lake Granby (LG)	0
Windy Gap Storage in Chimney Hollow (CH)	90,000
First Year Potential Regional Pool	0

Table 2.2 - C-BT M&I Ownership and Demand and Agricultural Demand

Item Name	Item Value
Initial M&I C-BT Units (1000 of units)	263.5
Annual Percent Increase in M&I Units (%)	0
Final M&I C-BT Units (1000 of units)	263.5
Initial Average M&I C-BT Demand (thousand acre-feet)	146.7
Annual Percent Increase in M&I Demand (%)	0
Final Average M&I C-BT Demand (thousand acre-feet)	146.7
Lease M&I Surplus C-BT to Agriculture	On

Table 2.3 - Windy Gap Input Settings

Windy Gap Item Name	Item Value
Project On/Off	On
In-Lieu Program	Off
Firming Project	On
Units not in Firming Project	40
Units in Firming Project	440
Demand, Non-Firming Project Participants (thousand acre-feet)	4
Demand, Firming Project Participants (thousand acre-feet)	26
Max Annual Firming to Move to Chimney Hollow (thousand acre-feet)	30

Table 2.4 - Additional Model Inputs

Item Name	Item Value
Annual Carryover Program Shrink (%)	10
Carryover Limit (%)	20
Regional Pool Program	On
Non-Charge Program	On
East Slope C-BT Priority Diversions	On

2.2 PBN MODEL

Baseline settings in the PBN model will be the same as those described in the CTP Modeling Report (CDM Smith, 2013). No additional adjustments will be made. A new suite of hydrologic traces based on the current climate were developed for this Study, as summarized in *Future Hydrologic Analysis TM #6*. These traces change some of the inputs to the PBN and will be used in the non-baseline simulated scenarios.

2.3 FC SYSTEM MODEL

The FC System Model Data Management System (DMS) controls inputs to the MODSIM model that simulates operations of the Fort Collins water supply system. This section presents the baseline settings for the DMS input controls organized similarly to how they are presented in the DMS.

- **Table 2.5** shows the baseline settings for the Halligan Reservoir input controls. Halligan Reservoir is assumed to be enlarged as described in the draft Halligan Reservoir Enlargement EIS documents for baseline conditions.
- **Table 2.6** shows the baseline settings for the demand input controls.
- **Table 2.7** shows the baseline settings for the water rights input controls.
- **Table 2.8** shows the baseline settings for the C-BT project input controls.

Table 2.5 - Halligan Reservoir Input Settings

Reservoir Input Item	Item Value
Reservoir Size (acre-feet)	8,125
Initial Volume (% of Total)	90
Link to LCUwc Season Capacity, acre-feet/year	2,388

Table 2.6 - Demand Input Settings

Demand Input Item	Item Value (acre-feet/year)
Large Contractual User – Single Use	3,004
Large Contractual User – Wholly Consumable	5,110
Population-Based Demand	28,304
Total Demand	**36,418**

Table 2.7 - Water Right Input Settings

Water Right Item	Item Value (Useable Shares)
C-BT	18,855
NPIC	3,563.75
NPIC # CBT units per share	3.2
WSSC	26.42
PVLC	201.21
New Mercer	59.62
Larimer Number 2	79.53
Arthur	440.88

Table 2.8 - C-BT Input Settings

Item Name	Item Value
C-BT Obligations, Total (shares)	3,411
% Reduction for Pipeline Decrees (%)	0
C-BT Rentals	Off
C-BT Carryover	On

The Total Demand value for the baseline modeling (Table 2.6) differs from previous modeling efforts due to how two specific demands are being captured in the updated modeling structure. The new modeling structure explicitly captures reuse plan related demands as part of the new Reuse Plan construct. The Large Contractual User – Wholly Consumable demand and the C-BT Obligations demand are therefore reduced accordingly. Additionally, the previous population-based demand value included demands related to an agreement with Fort Collins-Loveland Water District. This demand is now captured as part of the C-BT Obligation value in Table 2.8, as it better reflects operations. It should be noted that for the Baseline simulations, Colorado State University (CSU) is included within the population-based demand (as shown in table 2.6), but future scenario simulations, that use the Demand Tool, will reference CSU's contractual obligations as a Large Contractual User – Single Use demand.

3.0 SCENARIOS FOR SIMULATION

Scenarios of risks and uncertainties for simulation were assembled by Utilities and Northern Water staff. When assembling scenarios, there were several categories with different options that could be selected. This section summarizes the categories for simulation and identifies the options for consideration. Additionally, subsection 3.5 presents the identified scenarios that will be simulated, including the baseline. Model settings for these scenarios are assumed to be a future condition that is not necessarily tied to a specific year. Hydrology is run over a wide range of temperature and precipitation combinations that could take place anytime between now and a distant future year. Demand scenarios are developed through a demand model with inputs based on potential future scenarios. Finally, system risks are events that could happen anytime between now and the distant future.

3.1 HYDROLOGY

A new suite of hydrologic traces based on the current climate were developed for this Study, as summarized in *Future Hydrologic Analysis TM #6*. These traces include 100 synthetic traces of re-sequenced historical years and the historical hydrology, for a total of 101 available hydrologic traces. Due to simulation time constraints, not all 101 available hydrologic traces may be necessary for a given scenario. Therefore, a subset of 6 synthetic traces was selected from the full 100 using a process described in Section 2.4 of *Future Hydrologic Analysis TM #6*. This subset captures different drought types that are similar to, or more serve than droughts in the historical record to more robustly assess performance.

When assembling a scenario, it can have one of the three following hydrology options:

- Historical hydrology only
- Subset ensemble containing the 6 selected synthetic traces and the historical hydrology
- Full ensemble of 100 synthetic traces and the historical hydrology

Ultimately, each scenario simulated will be run under the full ensemble of 100 synthetic traces.

3.2 CLIMATE CHANGE SCENARIOS

The hydrologic traces, based on historical hydrology, as described in Section 3.1 can be adjusted by offsets in temperature and precipitation to capture the effects of potential future climate change. A total of 20 combinations of temperature and precipitation offsets (including no-change) can be applied to the hydrologic traces as described in *Future Hydrologic Analysis TM #6*. Temperature varies up to 8 degrees F warmer than current conditions, and precipitation varies between 10 percent drier and 15 percent wetter than current conditions.

When assembling a scenario, it can have one of the two following climate change options:

- No change in temperature or precipitation
- Full temperature and precipitation offset range (20 climate options)

3.3 DEMAND SCENARIOS

Demand scenarios will be generated by the Demand Model described in *Future Demand Estimating Methods TM #3.* In addition to representing effects of population growth,

development density and development type, demand forecasts from the Demand Model will be tied to overall climate (temperature and precipitation offsets), and the specific sequence of hydrology for each hydrologic trace. Utilities will choose two demand levels for simulation in future scenarios.

3.4 SYSTEM RISKS

System risks were identified and prioritized by staff from Utilities for their system and by staff from Northern Water for the C-BT system, as described in *Risks and Uncertainties TM #4*. The prioritized risks and uncertainties listed in **Table 3.1** were available for inclusion within a scenario. How these system risks are simulated is described in Section 4.1 of the *Risks and Uncertainties TM #4*.

Table 3.1 - List of Prioritized Utilities and Northern Risks and Uncertainties

ID	Risk or Uncertainty Name
A9a	Reuse Plan Gone
A9b	Reuse Plan Interrupted
AN2	Colorado River Hydrology Uncertainty / Major Outage of C-BT Project
D1	Demand Risks
O1	Outage – 24” Pipeline
O11	Outage - Pleasant Valley Pipeline
O17	Halligan Reservoir Not Enlarged
O18	No C-BT Carryover Storage
O2	Outage – 27” Pipeline
O3	Algal Blooms in storage reservoirs
O4	Outage - Michigan Ditch
O5	Outage - Horsetooth Reservoir Outlet
O8	Outage - Joe Wright Reservoir
ON12	Conveyance Systems to Horsetooth Outage
ON17	Farr Pump Plant Outage
ON18	Adams Tunnel Outage
ON19	Lake Granby Dam/Dike System Outage
ON20	Windy Gap Plant Outage
W1	Wildfires in Poudre Basin watershed
WN4	Wildfires – Northern East Slope

3.5 IDENTIFIED SCENARIOS FOR SIMULATION

Utilities Staff, in coordination with other stakeholders, identified 13 total scenarios for simulation, including baseline. These 13 scenarios are described below and summarized in **Table 3.2**. (Note: Utilities may revise one or more of these scenarios based on the results of the baseline analysis and pending simulations of individual system risks.)

- **Baseline** – As part of any vulnerability assessment, baseline conditions need to be established to quantify the negative impacts from other risks and/or uncertainties. The Baseline scenario developed for simulation in this study does not include any system risks, increased demands or climate-change influenced hydrology and the settings are listed in Section 2.0.

- **Climate Change Impacts** – Two of the highest perceived impactful risks were longer droughts not captured in the historical record and the compounding impacts of climate change (change in runoff volume and timing). This scenario includes the full hydrologic ensemble and a range of potential future climate change conditions. Because future climate change conditions include a no-change future, how climate change may worsen these drought conditions will be quantified. No additional system risks are included.

- **Loss of Storage** – Utilities presently has limited storage in their water supply system, potentially making them vulnerable to any future conditions where that limited storage is further reduced. This scenario captures the impacts to the water supply system if both the Halligan Reservoir expansion EIS is denied and Utilities loses their C-BT Carryover Storage account as decisions regarding both are ultimately beyond Utilities control. This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **Increased Demands** – While future demand estimates account for uncertainty in water use and population, a scenario was included to capture the impacts of uncertain future demand growth. This scenario captures two potential demands generated from the Demand Tool as well as an increased demand outside the current planning horizon that is a fixed percentage higher than the greatest Demand Tool trace. This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **Halligan Permitting Denial** – The baseline assumption includes the expansion of Halligan Reservoir, which at the time of Study has not competed the permitting process or been constructed. Because of the uncertainty around that assumption, this scenario is included to represent a future condition where the expansion of Halligan Reservoir expansion does not happen. This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **Poudre River System, Acute Outage** – Infrastructure to deliver yield from the Poudre River to the city is potentially vulnerable to failures due to either natural disasters (landslides or wildfires) or emergency maintenance outages. This scenario captures the impact of a short - term outage of the 24-inch Pipeline, the 27-inch Pipeline, and the Pleasant Valley Pipeline, which are simulated as one link in the FC System Model. This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **Poudre River System, Environmental Impacts** – Yields from the Poudre River are potentially vulnerable to prolonged environmental impacts that could cause constraints in delivery and treatment infrastructure. This scenario quantifies impacts on water supply performance due to algal blooms or environmental issues resulting from wildfires in source watersheds (e.g. increased sediment deposition). This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **C-BT System, Acute Outage** –Utilities receives a significant portion of their yield from the C-BT project; therefore, risks to that system are included in the vulnerability analysis. There are a variety of potential causes for a short-term outage of critical C-BT delivery

infrastructure such as an outage of the Adams Tunnel or Farr Pumping Plant. This scenario captures the impact of this C-BT infrastructure risk to the performance of the Utilities water supply system. This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **C-BT System, Long-Term Reduction** – It is not possible to predict if or when actual flows in the Colorado River below Lake Powell will fall below 75 million acre feet on a 10 year rolling average, how long actual flows in the Colorado River below Lake Powell could be below 75 million acre feet on a 10 year rolling average, or whether and how such flows would, under the Colorado River Compact or Upper Colorado River Compact, affect Colorado-Big Thompson Project diversions. Given these uncertainties, for purposes of the Vulnerability Study, Utilities assumed that in the event of a long-term C-BT project outage, the C-BT quota will be set to 25% for a 10-year period. This assumption was made by Utilities based on total storage capacity in the C-BT system and the potential length of this type of outage. It is intended to capture the possible effects of a wide range of conditions that could affect C-BT deliveries over an extended period and does not represent any defined future Colorado River Basin or C-BT scenario.

- **Horsetooth Reservoir Outage** – Lack of redundancy with the Horsetooth Reservoir outlet works puts deliveries of Utilities' yield from this reservoir at risk. Recent problems with the outlet works have shown that this type of risk can occur; therefore, it was included as a scenario. This scenario will be applied across all climate change options and hydrologic trace ensembles.

- **Reuse Plan Changes** – There are future uncertainties around the Reuse Plan due to changes in water use and energy generation facilities, which are outside Utilities' control. This scenario captures impacts to water supply system performance due to either an elimination of the Reuse Plan or changes to it that reduce the available supply to Utilities. This scenario will be applied across all climate change options and hydrologic trace ensembles.

Table 3.2 - Summary of identified scenarios for simulation

ID	Scenario Name	Hydrology Trace	Climate Change	Demand Scenarios	System Risks
1	**Baseline**	Baseline trace	None	Baseline Demands	None
2	**Climate Change Impacts**	Full ensemble (101 traces)	All	Baseline Demands	None
3	**Loss of Storage**	Full ensemble (101 traces)	All	Two selected Demand Model Scenarios	No Halligan Expansion, no Carryover – Entire simulation period.
4	**Increased Demands**	Full ensemble (101 traces)	All	Two selected Demand Model Scenarios plus one Scenario with a fixed increase	None
5	**Halligan Permitting Denial**	Full ensemble (101 traces)	All	Two selected Demand Model Scenarios	No Halligan Expansion – Entire simulation period.
6	**Poudre River System - Acute Outage**	Full ensemble (101 traces)	All	Two selected Demand Model Scenarios	24 - inch Pipeline, 27 - inch Pipeline, and PVP. 100% outage for 12 months starting in October of year 10.
7	**CBT System - Environmental Impacts**	Full ensemble (101 traces)	All	Two selected Demand Model Scenarios	Algal blooms – CBT water use shut off for one year, June through October; East slope wildfires – effective for 3 years (CBTQ model) Both risks start in a randomly selected dry-year(1).

Note: (1) Dry year is selected by binning current hydrology into dry, average and wet groups. A random year is then selected from within the dry bin. The same random year is used for all “dry-year trigger” scenarios

4.0 CONCLUSIONS AND NEXT STEPS

Utilities staff set baseline assumptions for the three water resources models used in the Study to quantify impacts and assess vulnerability. Additionally, staff assembled hydrology, climate, demand, and system risk settings into 13 scenarios that capture a variety of potential future conditions that could threaten Utilities' water supply system. The next step is to simulate the conditions for each scenario and use the resulting water supply system metrics and level of service goals to identify the scenarios of concern to Utilities based on their impacts to water system performance.

The twenty-first century Colorado River hot drought and implications for the future

Bradley Udall[1,2] **and Jonathan Overpeck**[2,3]

[1]Colorado Water Institute, Colorado State University, Fort Collins, Colorado, USA, [2]Colorado River Research Group, Boulder, Colorado, USA, [3]Department of Geosciences and Department of Hydrology and Atmospheric Sciences, Institute for the Environment, University of Arizona, Tucson, Arizona, USA

Key Points:
- Record Colorado River flow reductions averaged 19.3% per year during 2000–2014. One-third or more of the decline was likely due to warming
- Unabated greenhouse gas emissions will lead to continued substantial warming, translating to twenty-first century flow reductions of 35% or more
- More precipitation can reduce the flow loss, but lack of increase to date and large megadrought threat, reinforce risk of large flow loss

Abstract Between 2000 and 2014, annual Colorado River flows averaged 19% below the 1906–1999 average, the worst 15-year drought on record. At least one-sixth to one-half (average at one-third) of this loss is due to unprecedented temperatures (0.9°C above the 1906–1999 average), confirming model-based analysis that continued warming will likely further reduce flows. Whereas it is virtually certain that warming will continue with additional emissions of greenhouse gases to the atmosphere, there has been no observed trend toward greater precipitation in the Colorado Basin, nor are climate models in agreement that there should be a trend. Moreover, there is a significant risk of decadal and multidecadal drought in the coming century, indicating that any increase in mean precipitation will likely be offset during periods of prolonged drought. Recently published estimates of Colorado River flow sensitivity to temperature combined with a large number of recent climate model-based temperature projections indicate that continued business-as-usual warming will drive temperature-induced declines in river flow, conservatively −20% by midcentury and −35% by end-century, with support for losses exceeding −30% at midcentury and −55% at end-century. Precipitation increases may moderate these declines somewhat, but to date no such increases are evident and there is no model agreement on future precipitation changes. These results, combined with the increasing likelihood of prolonged drought in the river basin, suggest that future climate change impacts on the Colorado River flows will be much more serious than currently assumed, especially if substantial reductions in greenhouse gas emissions do not occur.

Plain Language Summary Between 2000 and 2014, annual Colorado River flows averaged 19% below the 1906–1999 average, the worst 15-year drought on record. Approximately one-third of the flow loss is due to high temperatures now common in the basin, a result of human caused climate change. Previous comparable droughts were caused by a lack of precipitation, not high temperatures. As temperatures increase in the 21st century due to continued human emissions of greenhouse gasses, additional temperature-induced flow losses will occur. These losses may exceed 20% at mid-century and 35% at end-century. Additional precipitation may reduce these temperature-induced losses somewhat, but to date no precipitation increases have been noted and climate models do not agree that such increases will occur. These results suggest that future climate change impacts on the Colorado River will be greater than currently assumed. Reductions in greenhouse gas emissions will lead to lower future temperatures and hence less flow loss.

1. Introduction

A large number of studies over the last 25 years have considered the future runoff of the Colorado River (Figure 1) under climate change. Nearly all of these studies have cautioned that future warming will deplete the flow of the river, but the results have varied from minor to major [*Nash and Gleick*, 1991; *Christensen et al.*, 2004; *Milly et al.*, 2005; *Brekke et al.*, 2007; *Christensen and Lettenmaier*, 2007; *National Research Council*, 2007; *Seager et al.*, 2007; *Barnett and Pierce*, 2008; *Ray et al.*, 2008; *Barnett and Pierce*, 2009; *Rajagopalan et al.*, 2009; *Cayan et al.*, 2010; *Reclamation*, 2013; *Harding et al.*, 2012; *Seager et al.*, 2012; *Vano et al.*, 2012; *Ficklin et al.*, 2013; *Vano et al.*, 2014; *Ayers et al.*, 2016; *Milly and Dunne*, 2016]. In contrast, the latest U.S. Government assessment implies little or no change is likely because precipitation increases will be sufficient to maintain temperature-depleted flows [*Reclamation*, 2016]. Fifteen years into the twenty-first century, the emerging reality is that climate change is already depleting

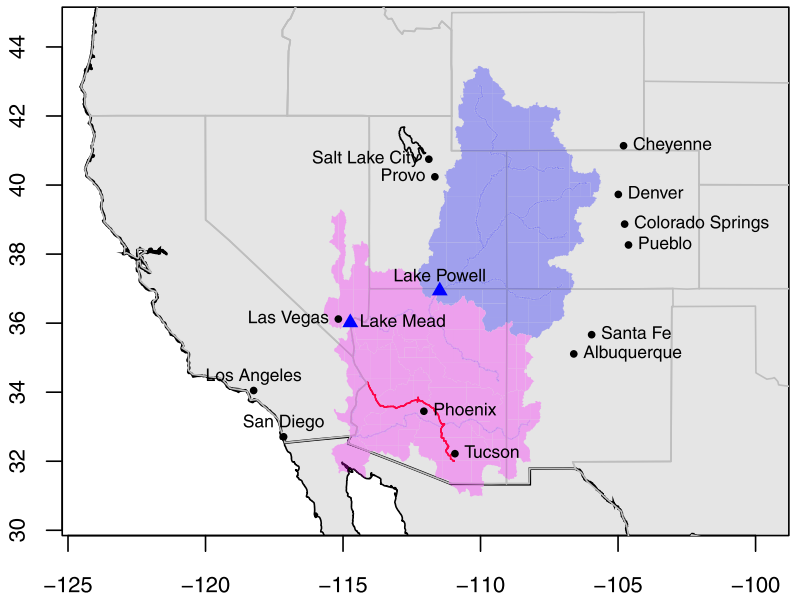

Figure 1. Map of the Colorado River Basin. Lower and Upper Basins, major U.S. cities receiving Colorado River water, major tributaries, and Lakes Mead and Powell are shown. The Central Arizona Project canal in red.

Colorado River water supplies at the upper end of the range suggested by previously published projections. Record setting temperatures are an important and underappreciated component of the flow reductions now being observed.

Between the start of the drought in 2000 and the end of 2014, our analysis period, annual flow reductions averaged 19.3% below the 1906–1999 normal period, and Lakes Mead and Powell, the nation's two largest reservoirs, ended the period at approximately 40% of maximum volume despite starting the period nearly full [*Wines*, 2014; *Colorado River Basin Stakeholders*, 2015] (Figure 2a). This drought has continued into 2015 and 2016 with higher, but still below normal, flows estimated at 94% in 2015 and 94% in 2016 with unusual late season May and June precipitation in both years that raised runoff by nearly 20% [*Alcorn*, 2015, 2016]. Despite these smaller recent reductions, Lake Mead continues to decline and in May 2016 it hit a level not seen since its initial filling in the 1930s [*James*, 2016]. The overall Colorado River reservoir system stores 4 times the annual flow of the river, one of the largest ratios in the world. This storage provides a large drought buffer when full. However, when the reservoirs are low, shortage risk can be high for years because high demands, now equal to twentieth century average flow, make it difficult to refill system storage [*Reclamation*, 2012]. While the multiyear California drought has been garnering more national attention, the more slowly unfolding Colorado River drought is every bit as serious and also has national and international ramifications [*Wines*, 2014].

The Colorado River Basin encompasses seven states and northern Mexico and is home to 22 federally recognized tribes. The river provides municipal and industrial water for 40 m people distributed across every major Southwestern city both within and without the basin, including Los Angeles, San Diego, Las Vegas, Phoenix, Tucson, Salt Lake City, Denver and the entire Front Range of Colorado, Albuquerque, and Santa Fe [*Reclamation*, 2012].

Continued low flows would result in additional declines at Lake Mead, eventually requiring Lower Basin (Arizona, California, Nevada) water delivery shortages with mandatory cutbacks imposed primarily on Arizona, but also Nevada and Mexico [*Verburg*, 2011]. At the same time, Upper Basin (Colorado, New Mexico, Utah, Wyoming) water users would continue to endure physical shortages from a lack of water. These initial Lower Basin Lake Mead delivery shortages and Upper Basin physical shortages are manageable to a point; however, under current operating rules with continued low flows during the next 6 to 8 years Lake Mead would drop to elevation 305 m (1000 feet) above sea level, resulting in a number of serious and unprecedented problems [*Collum and McCann*, 2014].

In the Lower Basin, Arizona could theoretically lose its water allocation for the entire Central Arizona Project canal, a critical $4.4B, 530 km cross-state 2 bcm/yr water source for 4.7 m people, multiple sovereign Indian

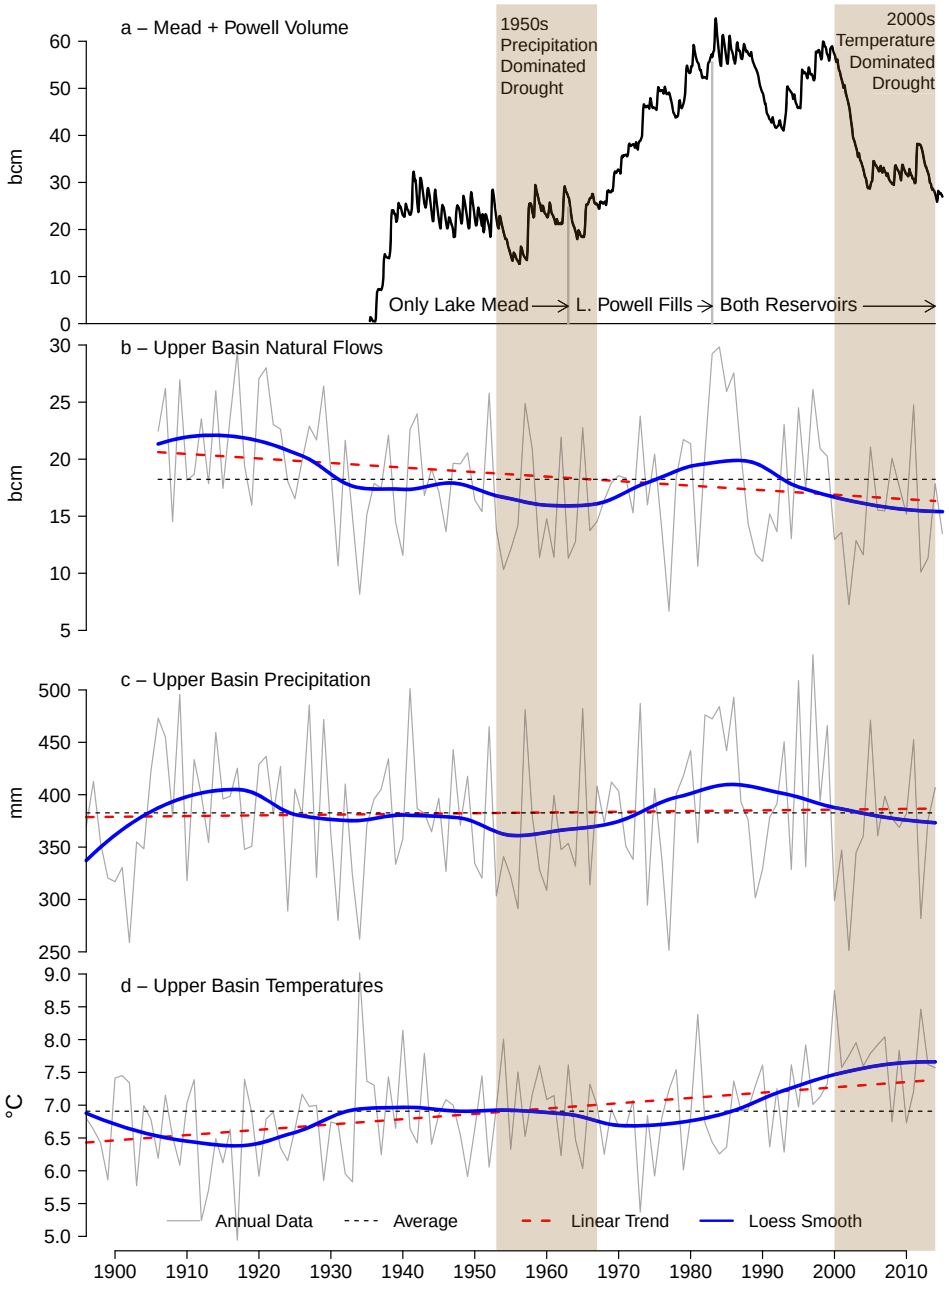

Figure 2. (a) Lakes Mead and Powell combined monthly contents. Upper Basin annual Colorado River (b) runoff at Lees Ferry from 1906 to 2014, (c) precipitation and (d) temperatures from 1896 to 2014. Mead first filled in 1935, Powell in 1963 (supporting information Text S1). Two 15-year drought periods, 1953–1967 and 2000–2014, are highlighted and discussed in main text.

nations, and over 120,000 irrigated hectares [*Glennon*, 1995; *Colorado River Basin Stakeholders*, 2015]. This canal currently relies on occasional but uncertain "equalization" releases from Lake Powell that only occur with irregular and rare large Powell inflows. The extra water is delivered when Lake Powell reaches levels substantially higher than Lake Mead, a use allowed under the 1922 Colorado River Compact section III (e) and formalized most recently under rules established in a 2007 Record of Decision for coordinated operations of Lakes Powell and Mead and for shortage sharing in the Lower Basin [*Department of Interior*, 2007].

Under normal operating rules, without these extra inflows, Lake Mead has excess outflows of 1.5 bcm per year, the so-called Lower Basin "structural deficit" [*Collum and McCann*, 2014]. The structural deficit was created in 1968 when Congress authorized the Central Arizona Project (CAP). In order to obtain the support of

AGU Water Resources Research 10.1002/2016WR019638

the large California Congressional delegation, Arizona agreed to rely on this unused, but in the long run unreliable water, because there was not enough remaining unallocated Lower Basin water. The CAP had long been a desire of Arizona and the state was willing to make this bargain despite its flaws [*Johnson*, 1977]. This same water is first available for use by the Upper Basin under the Colorado River Compact, but heretofore has not been developed for Upper Basin use. A plan to augment the Colorado River with flows from outside the basin, discussed during the hearings on the legislation, but not included in the final package due to opposition from potential source areas, was never revisited by Congress. Reclamation in 2011 said that such augmentation was now unlikely.

The structural deficit only became a problem when the CAP was fully completed in the mid-1990s combined with the drought that began in 2000. Upper Basin demand growth has also played a small role, although Upper Basin demands are still much less than forecast in 1968 for the year 2000 [*Tipton and Kalmbach, Inc*., 1965; *Johnson*, 1977]. The recent Lake Mead declines are strongly influenced by this imbalance, and solutions to this deficit have been a recent focus of the Basin states and federal government [*Central Arizona Project*, 2016; *Davis*, 2016].

The Upper Basin also has serious issues, one of which ripples into the Lower Basin. When the surface of Lake Mead declines to an elevation 305 m (1000 feet) above sea level, Lake Powell will also be below its minimum power pool 75% of the time [*Collum and McCann*, 2014]. This occurs in part because low Mead levels make "equalization" releases from Powell more likely thus driving Powell lower. Hydropower losses at Lake Powell could result in substantial rate increases for irrigators who rely on the reservoirs for long term lower cost power contracts, and would also dry up funding for basin-wide programs necessary for water delivery environmental compliance [*Adler*, 2007; *Collum and McCann*, 2014]. Under such low reservoir conditions, there is also a high likelihood that the Upper Basin states would have to curtail existing water deliveries to cities such as Denver, Colorado Springs, Albuquerque and Salt Lake City in order to make required deliveries to Lake Mead. Heretofore, largely because of the structure of the Colorado River Compact, the Upper Basin and Lower Basin have been managed separately. With permanent flow declines of approximately 20%, however, the required deliveries to Lake Mead would become a hardship on the Upper Basin, as well as create Lower Basin delivery shortages [*Reclamation*, 2007; *Barnett and Pierce*, 2009; *Rajagopalan et al*., 2009]. The original compact, signed during one of the wettest periods in the last 450 years [*Woodhouse et al*., 2006], did not envision how large scale flow declines would be managed between the basins, and such declines could cause an allocation crisis between the Upper and Lower Basins [*Adler*, 2008].

Understanding the cause of, and reacting properly to, the ongoing drought is critical to the future of the Southwest. Herein we investigate the role of precipitation versus temperatures as causes of the current drought, provide temperature-based and precipitation-based twenty-first century flow projections and provide policy implications of these findings. Our approach separates the impacts of high-confidence temperature projections from those associated with the much lower-confidence projections of future precipitation using a simple but powerful sensitivity technique. Moreover, we make a novel—and important—case that there is a high likelihood that the impacts of continued atmospheric warming will overwhelm any future increases in precipitation because prolonged dry periods lasting multiple decades are likely to negate the beneficial impacts of additional precipitation during other times.

2. Causes of the 2000–2014 Drought

The 2000–2014 drought is defined by the lowest average annual flows for any 15-year period in the historical record. To analyze this drought, gridded 4 × 4 km temperature and precipitation data from 1896–2014 for the area above Lees Ferry were obtained from the Precipitation-Elevation Regression on Independent Slopes (PRISM) model [*Daly et al*., 1994; *Guentchev et al*., 2010; *Oyler et al.,* 2015a, 2015b; *Rangwala et al.,* 2015]. In addition, we obtained reservoir contents and natural flows at Lees Ferry from the U.S. Bureau of Reclamation (Reclamation) (Text S1). Lees Ferry is situated just below Lake Powell and is the Compact dividing line between the Upper and Lower Basins. Approximately 85% of the flow originates above Lees Ferry [*Christensen and Lettenmaier*, 2007].

Historically, Upper Colorado River Basin precipitation has been the main Colorado River runoff driver such that high flow years (1920s, 1980s) were associated with high precipitation and low flow years (1930s, 1950s) with low precipitation (Figures 2b and 2c). The current drought (our study period is 2000–2014, but

Table 1. Winter/Summer/Annual Upper Basin Mean Water Year Precipitation

	1953–1967			2000–2014			1896–2014	
	mm			mm			mm	
	Total	Anomaly	Anomaly % of Mean (%)	Total	Anomaly	Anomaly % of Mean (%)	Mm	% Avg
Winter (Oct to Mar)	176	−16	−8.6	187	−5	−2.7	192	100
Summer (Apr to Sep)	184	−7	−3.6	179	−12	−6.4	191	100
Total	359	−23	−6.1	365	−17	−4.6	383	100

the drought is still on-going), with its modest −4.6% precipitation decline and −19.3% flow decline, stands in stark contrast to the second-lowest 15-year flow period (1953–1967), a precipitation-driven drought with averaged precipitation reductions of −6.1% per year and flow reductions of −18.1% per year (Figures 2b and 2c and Table 1). Compared to the 1950s drought, the 2000s feature much more (near normal) winter precipitation (−8.6% 1950s decline versus −2.7% 2000s) and significantly less summer precipitation (−3.6% 1950s decline versus −6.4% 2000s). The 2000s precipitation decline is only 75% of the decline in the 1950s, thus begging the question of why the recent drought was more serious. What has changed is that temperatures in the runoff producing Upper Basin are now 0.9°C above the 1896–1999 average and are the highest in the gaged record; whereas temperatures during the 1953–1967 drought were much cooler and only slightly above the 1896–1999 average (Figure 2d and Table 2). This makes the current drought unprecedented in the gaged record.

In contrast to the more precipitation-driven current California drought [*Diffenbaugh et al*., 2015; *Williams et al*., 2015], lack of precipitation is only partially to blame for the Colorado River runoff declines during the last 15 years. Instead, approximately a third, or more, of the recent Colorado River flow reduction is most likely a result of record-setting warmth. Since 1988 an increase in the frequency of warm years has been strongly associated with lower flows than expected [*Woodhouse et al*., 2016], suggesting an important role for temperature in flow losses. Such temperature-driven droughts have been termed "global-change type droughts" and "hot drought," with higher temperatures turning what would have been modest droughts into severe ones, and also increasing the odds of drought in any given year or period of years [*Breshears et al*., 2005; *Overpeck*, 2013]. Higher temperatures increase atmospheric moisture demand, evaporation from water bodies and soil, sublimation from snow, evapotranspiration (ET) from plants, and also increase the length of the growing season during which ET occurs [*Pitman*, 2003; *Weiss et al*., 2009; *Seneviratne et al*., 2010; *Seager et al*., 2015a]. Warm season (April to September) warming has been identified by models as especially important in reducing Colorado River flows because of the increases in ET from longer growing seasons [*Das et al*., 2011]. Increases in measured vapor pressure deficits in the Southwest caused by warming and a decrease in water vapor provide strong support for higher ET during the recent drought [*Seager et al*., 2015b]. As increasing temperatures drive further drying, additional positive feedbacks are possible in the form of lower humidity and less evaporative cooling, decreased cloudiness and increased incident radiation, as well as decreased snow cover and more radiative heating [*Betts et al*., 1996; *Brubaker and Entekhabi*, 1996; *Pitman*, 2003; *Seneviratne et al*., 2010]. In the twentieth century, droughts were associated almost exclusively with a lack of precipitation. In this century, however, high temperatures alone can lead to anomalously dry conditions.

Table 2. Upper Basin Water Year Flows and Temperatures

	Average Annual Flow		Average Annual Temperature	
Period	bcm	% 1906–1999	°C	°C Anomaly to 1896–1999
1953–1967	15.38	81.9	7.0	0.2
2000–2014	15.15	80.7	7.7	0.9
1906–1999	18.77	100.0	6.8	0.0
1906–2014	18.27	97.3	6.9	0.1

3. Estimates of 2000–2014 Temperature-Induced Flow Loss

Over the last several years several studies specific to the Colorado River Basin have investigated the specific relationships among temperatures, precipitation and flow in the basin using the concepts of temperature

AGU Water Resources Research 10.1002/2016WR019638

sensitivity and precipitation elasticity [*McCabe and Wolock*, 2007; *Nowak et al*., 2012; *Vano et al*., 2012, 2014; *Vano and Lettenmaier*, 2014]. Temperature sensitivity is defined as the percent change in annual flow per degree rise in annual temperature. Precipitation elasticity is defined as the fractional change in annual flow divided by the fractional change in annual precipitation [*Vano et al*., 2012]. Note that elasticity has been studied for both increases and decreases in precipitation, whereas sensitivity is typically investigated only for temperature increases. These numbers can be determined empirically and through model studies.

Previous studies on temperature sensitivity and precipitation elasticity show that future impacts to streamflow from increases in temperatures and changes in precipitation can be considered separately using sensitivity and elasticity, and then added together to produce flow estimates [*Vano et al*., 2014; *Vano and Lettenmaier*, 2014]. Considering these effects separately and additively is a powerful conceptual tool for investigating climate change impacts because of the ease in measuring the two variables for current impacts and the wide availability of temperature and precipitation projections from global climate models for assessing future impacts. In addition, the large differences in certainty associated with future changes in the two variables (temperature will surely increase, whereas precipitation may increase or decrease—see below) helps to set apart the risk of future changes in flow associated with each variable.

Vano et al. [2012, 2014], *McCabe and Wolock* [2007], and *Nowak et al*. [2012] provide multiple estimates of the flow sensitivity of the Colorado River flow to temperature using three different methods. *Vano et al*. [2012, 2014] utilized six high-resolution, commonly used hydrology models and two different temperature adjustment methods to obtain Lees Ferry temperature sensitivities. They report an average sensitivity of −6.5%/°C warming with a one standard deviation range from −3.0% to −10.0%/°C for the Upper Basin. Approximately 50% models show increasing sensitivity and 50% decreasing sensitivity as temperatures warm so we elect to use a constant sensitivity over all future temperatures. *McCabe and Wolock* [2007] constructed a simple water balance model that infers an average temperature sensitivity of −8.9%/°C and *Nowak et al*. [2012] found an empirical temperature sensitivity of −13.8%/°C.

We use the complete one standard deviation range (−3%/°C to −10%/°C) of the *Vano et al*. [2012, 2014] temperature sensitivity estimates as they were the most conservative and rigorous of the three studies we investigated. Using this range, we found that recent warming of 0.9°C has likely already reduced river flows from −2.7% to −9% from the mean 1906–1999 flow. This represents approximately one-sixth to one-half (average of one-third) of the total flow loss during the 2000–2014 drought.

The higher temperature sensitivities of the two other studies suggest the actual Colorado River temperature sensitivities are near the upper end and possibly exceed the *Vano et al*. [2012, 2014] estimates. These higher sensitivities imply much greater temperature-induced losses during the current drought (−7.9% to −12.3% versus −2.7% to −9%). Empirical results from the 2000 to 2014 drought also point to mid to high temperature sensitivities. *Vano et al*. [2012] report precipitation elasticities ranging from 2 to 3 at Lees Ferry. Thus, using a midrange precipitation elasticity of 2.5, the 2000–2014 annual −4.6% precipitation decline implies runoff reductions of −11.4%, leaving the remaining −7.9% decline to be explained by other causes. If temperature were the sole cause of this remaining decline, the inferred temperature sensitivity is −8.8%/°C. Using a precipitation elasticity of 3.0 implies a temperature sensitivity of −6.2%/°C, very close to the midrange Vano et al., sensitivity. These temperature sensitivities imply large losses as temperatures rise, the subject of the next section.

4. Twenty-First Century Flow Response to Changing Temperatures and Precipitation

For the analysis on how future temperatures and precipitation would affect runoff, and for investigating how well current linked climate-hydrology models can reproduce the current drought, we used Reclamation's climate projection data sets [*Brekke et al*., 2013, 2014]. These data sets use Coupled Model Intercomparison Project 3 and 5 (CMIP3, CMIP5 after the class of climate models used) climate model projection data linked to the Variable Infiltration Capacity hydrology model to produce flows from 1950 to 2099 (supporting information Text S2, Figures S2, and S3)] [*Liang et al*., 1996; *Meehl et al*., 2007; *Moss et al.,* 2010; *Taylor et al*., 2012].

The same temperature sensitivity and precipitation elasticity numbers discussed above can be used to estimate future flow reductions using climate model outputs under high (business-as-usual, SRES A2 and

AGU Water Resources Research 10.1002/2016WR019638

RCP8.5) and moderate (somewhat reduced by mitigation, SRES A1B and RCP4.5) greenhouse gas emissions to the atmosphere. By 2050, moderate and high emissions are projected to yield Upper Basin *mean* warming of 2.6–2.8°C (Figure 3), three times recent warming, and by 2100, warming of 3.6°C under moderate emissions and 5.4°C under high emissions. This warming implies total multimodel mean temperature-induced flow losses at midrange sensitivity of −6.5%/°C of about −17% by midcentury and −25% to −35% at end-century (Figures 4 and 5). The multimodel mean complete flow loss *range* over both periods and both emissions is approximately −8% to −55% using the lower and upper temperature sensitivities (Figures 4 and 5). As discussed above, there is little empirical evidence that the true temperature sensitivity of flow to temperature increase is near the low sensitivity.

Temperature-induced losses may be somewhat buffered by projected additional precipitation that can increase runoff by 2–3% for every 1% change in precipitation [*Vano et al.*, 2012]. At midcentury precipitation increases of +4–+11% given a midrange elasticity of 2.5 would balance the range of temperature-induced flow losses at a midrange—6.5%/°C sensitivity (Figure 5, right *y* axis). At end-century, with the same sensitivity and elasticity, additional precipitation increases of +4–+20% would balance the range of possible temperature-driven losses. At a higher −10%/°C sensitivity, the balancing precipitation would need to be as great as +15% or more at midcentury and +22% or more at end-century. While these may seem like relatively small increases in precipitation, and thus possible, they would represent a major and unprecedented change in precipitation regime compared to the observed historical variation in precipitation (Figure 2c). During the twentieth century, for example, the wettest 10-year period (1983–1997) had only a +8% precipitation increase. This unusual period was marked by major floods downstream of Lakes Powell and Mead due to uncontrolled reservoir spilling and the near catastrophic loss of the spillways at Glen Canyon Dam [*Udall*, 1983].

Vano and Lettenmaier [2014] argue that the sensitivity-based approach used in our projections provides similar estimates of future streamflow to those generated with more computationally intensive coupled-model methods, except for some (i.e., 10%) overstatement of flow reductions at the highest levels of possible warming by 2100 (e.g., the business-as-usual SRES A2 scenario used in the CMIP3 projections and the RCP8.5 in the CMIP5 projections). This would reduce the end of century high emissions mean flow reductions shown in Figure 5 to a still very significant −45% by 2100.

Recent studies have suggested that CO_2 fertilization may increase plant water efficiency thus reducing future evapotranspiration which could serve to mitigate our projected losses [*Milly and Dunne*, 2016; *Swann et al.*, 2016]. Both studies call into question results that show large portions of the globe drying in the twenty-first century [e.g., *Dai*, 2012; *Cook et al.*, 2014]. However, *Milly and Dunne* [2016] and *Swann et al.* [2016] show that, despite this increase in plant water use efficiency, the Southwestern US will still dry, a finding that is consistent with multiple global assessments showing substantial drying risk to midlatitude areas such as the Colorado River Basin. Moreover, a recent Australian study found that higher

AGU Water Resources Research 10.1002/2016WR019638

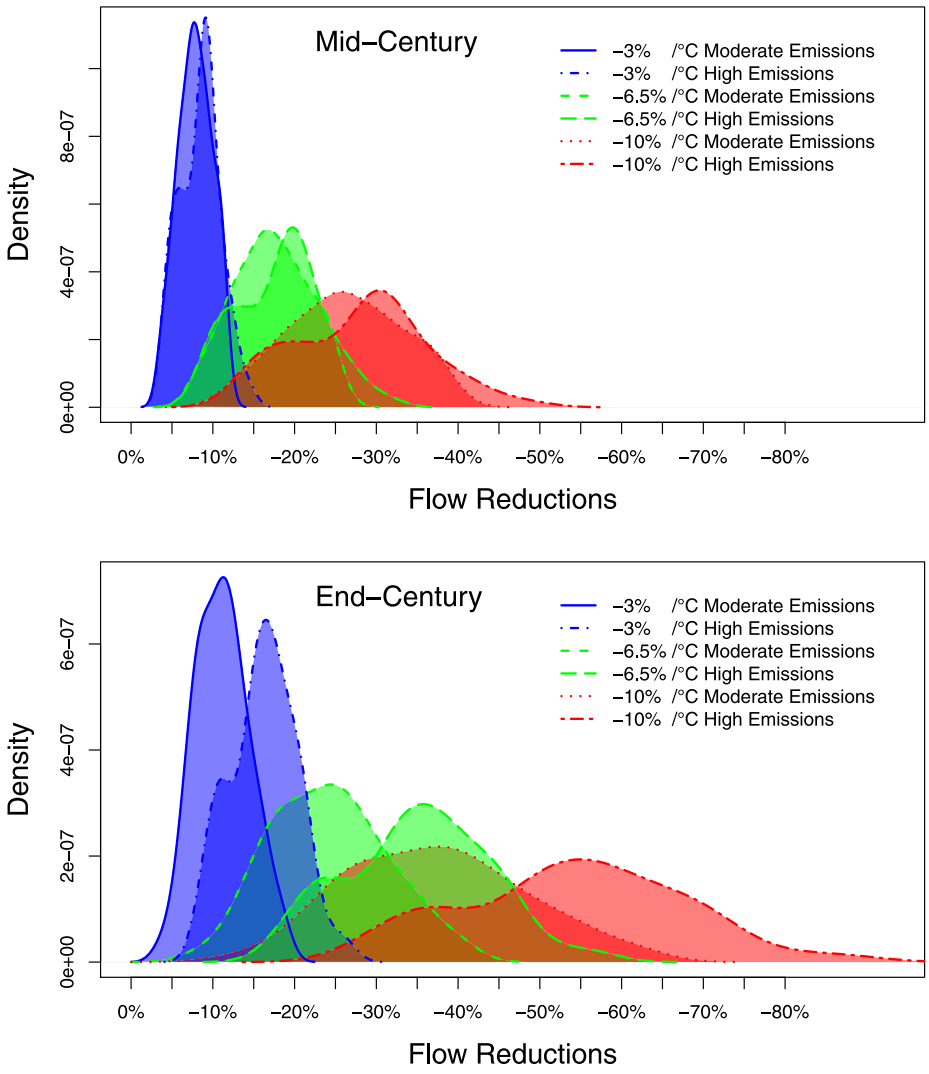

Figure 4. Probability density functions of Upper Colorado River Basin temperature-induced flow reductions for midcentury and end-century with the three temperature sensitivities (−3%, −6.5%, −10%) and the two levels of emissions (Moderate: SRES A1B and RCP4.5 and High: SRES A2 and RCP8.5).

evapotranspiration associated with the increased plant growth stimulated by higher CO_2 outweighed any CO_2-related water-use efficiency effect, and served to reduce streamflows in semiarid regions [*Ukkola et al.*, 2015], a trend that must be exacerbated by the temperature-induced lengthening of the growing season. These results suggest that plant physiological responses are likely consistent with our results, and in any case, do not invalidate them.

5. Megadrought Risks to Flows

Megadroughts lasting decades in the Colorado River Basin have occurred in the past, with resulting substantial flow reductions [*Meko et al.*, 2007]. Multiple papers now suggest there is high twenty-first century risk for megadrought in the American Southwest and that the risk will increase as temperatures rise [*Ault et al.*, 2014; *Cook et al.*, 2015; *Ault et al.*, 2016]. In addition, current GCMs underrepresent the frequency of megadrought [*Ault et al.*, 2012, 2013]. These findings provide additional support for large flow reductions during at least multidecadal drought periods and suggest that current twenty-first century flow projections underrepresent this risk.

Significant Colorado River flow losses occurred during previous multidecadal megadroughts. During the twelfth century, flow reductions of approximately −16% occurred during one 25-year period [*Meko et al.*,

AGU Water Resources Research 10.1002/2016WR019638

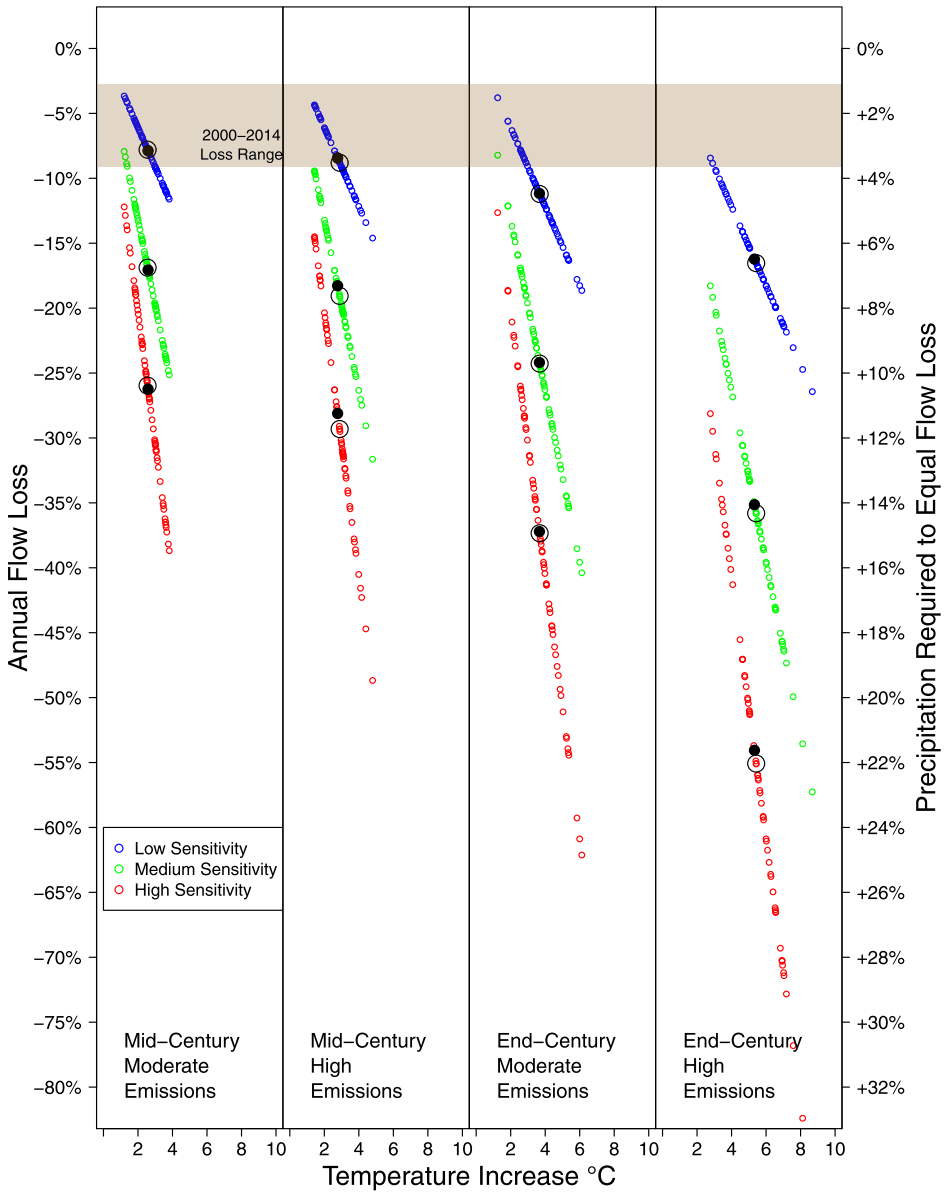

Figure 5. Temperature-induced flow losses by model run (one per dot) with temperature increases shown on horizontal axis. For each period (midcentury, end-century) and emissions type (moderate, high), flow losses for each model run are shown with the 3 (low = −3%/°C, medium = −6.5%/°C, high = −10%/°C) temperature sensitivities. Black dots/circles are averages/medians for each sensitivity. Precipitation increases needed to counteract flow losses at right are based on 2.5 precipitation elasticity. Range for the temperature-induced losses during 2000–2014 drought are shown in shaded brown at the top (supporting information Text S5).

2007]. Evidence indicates that hemispheric and Southwest temperature anomalies were significantly smaller during past megadroughts than the rapid on-going current warming that could easily exceed 4–5°C by the end of century under business-as-usual emissions [*Salzer and Kipfmueller*, 2005; *Mann et al.*, 2009; *Salzer et al.*, 2014] (Figure 5). Using the additivity concepts discussed above, additional warming of 1°C, 2°C, or 3°C beyond the historic twelfth century megadrought temperatures would have reduced the −16% flow declines by an additional −6.5%, −13%, or −19.5% at medium temperature sensitivity. These additional reductions would have thus turned a −16% flow decline into declines of −21.5%, −28%, or −34.5%, losses near the middle of our projections.

There is recent strong evidence that continued warming over the next 80 years could increase the risk of multidecadal drought [*Ault et al.*, 2014, 2016; *Cook et al.*, 2015]. Independent of the added drought risk due

AGU Water Resources Research 10.1002/2016WR019638

to continued warming, the risk of a 35-year precipitation-deficit drought later in this century exceeds 15% within a 50-year period [*Ault et al*., 2014]. In contrast, with continued anthropogenic warming, the risk of multidecadal megadrought in the Southwest increases to over 90% over this century if there is no increase in mean precipitation; even if modest precipitation increases do occur, the risk will still exceed 70% [*Ault et al*., 2014, 2016]. At medium warming (4°C), 20–30% precipitation increases will be needed to reduce megadrought risk below 50% and at high amounts of warming (>6°C), it will take a ~40% increase in precipitation to reduce megadrought risk below 50% [*Ault et al*., 2016]. These changes in precipitation are huge and unlikely, and they would still only reduce megadrought risk to below 50%.

Both the CMIP3 and CMIP5 Global Climate Models may not adequately reproduce the frequency of occurrence of known past decadal and multidecadal precipitation droughts [*Ault et al*., 2012, 2013]. In the Colorado River Basin empirical evidence of this problem can be found in the linked GCM-hydrology model results from Reclamation's projections for the basin [*Brekke et al*., 2014]. Approximately half of the CMIP5 models and one-quarter of the CMIP3 models cannot simulate the 2000–2014 drought at any point in the twenty-first century (supporting information Text S3 and Tables S1–S4). This wet bias significantly affects the mean flows of drought-capable and nondrought capable models. At the end of the twenty-first century, the models unable to simulate the current drought are much wetter (109% of twentieth century average Lees Ferry runoff for CMIP3, 113% for CMIP5) than the models that are able to simulate the current drought (85% of average runoff for CMIP3, 91% CMIP5) (supporting information Tables S1–S4). These flow differences are greater than 20%, and represent the difference between serious management challenges and significant oversupply.

6. Risk-Based Framing of Future Runoff Projections

At present, some outputs from global climate models are ready to support reliable risk-based policy while others are not as ready. A key novel aspect of our research is to provide more insight into where confidence is warranted, and where it is not, with respect to projections of future climate and flow change in the Colorado River Basin. In the case of the Basin, every single moderate and high emissions model simulation agrees that temperatures will continue to rise significantly with continued emissions of greenhouse gases to the atmosphere—this result is robust, highly certain and well-suited for informing policy choices. The fact that observations also show substantial warming only strengthens this assertion.

On the other hand, simulated future precipitation change in the Basin is clouded with much greater uncertainty due to substantial disagreement among models and a highly uncertain ability to simulate realistic change in key phenomena such as storm-track position or decadal and longer-scale drought. Whereas climate models are in general agreement that cool season (warm season much less certain) precipitation declines are likely in the Lower Colorado River Basin, these same models disagree when it comes to the sign and amount of precipitation change that is likely in the Upper Basin. This is because precipitation change in the Upper Basin will depend heavily on the exact changes in the position of cool season jet stream and storm-tracks, two aspects of climate change that are not simulated with confidence by global climate models [*Collins et al*., 2013].

Moreover, there is strong evidence that the mean positions of both the jet stream and storm-tracks are likely to push poleward, expanding the area of aridity in the Colorado River Basin, but the amount of this expansion is poorly constrained [*Collins et al*., 2013]. Multiple studies, including some focused on the American Southwest, suggest that the proximate cause of this drying, Hadley Cell expansion, is already well underway and will continue [*Seager et al*., 2007; *Scheff and Frierson*, 2012; *Feng and Fu*, 2013; *Norris et al*., 2016; *Prein et al*., 2016].

Our results regarding future changes in Colorado River flows agree with many previous studies in suggesting climate change translates to flow reductions, although our work is generally not directly comparable because we separate out high confidence temperature-related impacts from the possible effects of much less certain and highly variable precipitation projections. However, our work, as well as this larger body of literature, appears to be at odds with the recent Reclamation projections for the Colorado River Basin, which are widely cited and used. Reclamation's projections use a global climate model output that is downscaled to drive a hydrology model. It is worth understanding why our results emphasize substantially greater risks along with apparently greater flow losses.

AGU Water Resources Research 10.1002/2016WR019638

The 2011 CMIP3 climate change flow projections by Reclamation indicate a modest multimodel median flow decline of −9% by 2060 for the river, but with a wide range of outcomes from flow increases to flow decreases [*Reclamation*, 2012] (supporting information Table S1). Reclamation's most recent CMIP5 projections show no change in mean and median basin-wide flow by 2070s [*Reclamation*, 2016], but also embody a wide range of results. Compared to CMIP3, the CMIP5 results show increased precipitation, especially in the northern parts of the basin including Northeast Utah, Northwest Colorado's Yampa River and the Green River in Wyoming [*Brekke et al*., 2014; *Ayers et al*., 2016] (supporting information Tables S1 and S3). The increased precipitation in the CMIP5 model runs compared to CMIP3 can be attributed to more southerly storm tracks in CMIP5 that occur in late spring [*Brekke et al*., 2014].

Another issue arises in both the CMIP3 and CMIP5 data sets when GCM precipitation is adjusted by the downscaling techniques necessary for off-line hydrology models. The first step in Reclamation's downscaling is a bias correction step. This step can add approximately 5% more precipitation to the raw GCM precipitation, and this increase appears to not have a physical basis [*Reclamation*, 2013; *Brekke et al*., 2013]. The final downscaling step, spatial downscaling, also increases GCM precipitation, although there is at least a plausible physical explanation for some of the increase: higher elevations in the Rockies receive large amounts of precipitation, but these elevations are not properly modeled by the GCMs. In one study of the CMIP5 data set after downscaling, dry and average models show precipitation increases of approximately +∼5% from the raw GCM output, but the wettest models show +∼10% increases, doubling future precipitation increases from +10% to +20% [*Lukas et al*., 2014]. This extra precipitation is manifested in a number of hydrology model runs that project huge and implausible flow increases in some years that are 150% of the highest known flows in the twentieth century (supporting information Text S4, Figures S2, and S3). The downscaling wetness problem has been identified, but has not been not resolved [*Lukas et al*., 2014]. Reclamation acknowledges that the newer CMIP5 projections have not been determined to be better or more reliable [*Brekke et al*., 2014]. It is noteworthy that internally consistent GCM-only Southwest runoff projections almost uniformly produce significant declines in both CMIP3 and CMIP5 runs [*Milly et al*., 2005; *Seager et al*., 2007, 2012; *Koirala et al*., 2014; *Milly and Dunne*, 2016].

Our results are generally comparable to Reclamation's most recent results when considering the full range of our analysis when both precipitation and temperatures are included. However, our focus and emphasis is on the large near-certain temperature-induced flow declines with a separate analysis of precipitation. Reclamation, by contrast, has a focused on climate multimodel-ensemble median declines, including medians calculated across emission scenarios [*Reclamation*, 2013, 2012]. Decision makers often treat these median outcomes as a proxy for risk despite the fact that the median obscures the wide range of results and lumps wet and dry, warm and hot, large and small emission increases and, most critically, near certain temperature increases and very uncertain precipitation changes.

We assert that the large precipitation increases necessary to offset substantial temperature-induced flow decreases appear unlikely to occur for a number of reasons. These reasons include the potential for storm tracks to go north of the basin due to Hadley Cell expansion, the high potential for megadrought to increase evaporation while reducing precipitation and runoff for extended periods, the large size of the needed precipitation increases, especially when compared to decadal historical increases, the consistent identification by global assessments of the Southwest as an area likely to dry, and finally the lack of any trend over the last century or last 16 years (Figure 2c). Hence, we choose to focus on highly likely temperature-induced declines with separate analysis of the precipitation needed to offset these declines.

7. Policy Implications and Solutions

The climate science take-home messages for Colorado River managers are thus: (1) there is little doubt (i.e., high confidence) that temperatures will continue to increase as long as the emissions of greenhouse gases to the atmosphere continue; (2) there is also high confidence that continued temperature increases will cause river flows to decline, ranging from −11% to as much as −55% by end of century under moderate to high emissions (Figures 4 and 5); (3) there is only low confidence associated with the possibility of storms and precipitation in the Upper Basin increasing enough to even partially offset the temperature-driven declines in river flows; (4) the risk of multidecadal megadrought in the Basin is significant even in the absence of continued anthropogenic climate change, and this risk rises substantially with continued global

AGU Water Resources Research 10.1002/2016WR019638

warming; (5) the likelihood of drought and megadrought means that there will likely be decades-long periods with anomalously low runoff even if there is an increase in precipitation relative to the historical mean during some other periods due to anthropogenic climate change.

Temperature-driven threats to the flows of the Colorado are thus large and real. The only way to curb substantial risk of long term mean declines in Colorado River flow is thus to work toward aggressive reductions in the emissions of greenhouse gases into the atmosphere. Our work shows that modest (e.g., RCP4.5) reductions in greenhouse gas emissions, while having better outcomes than the business-as-usual future (e.g., RCP8.5), still imply large Colorado River flow losses.

The record warm nature of the on-going Colorado River drought indicates that this drought is not just a natural drought, and our work demonstrates that flows are unlikely to return to the twentieth century averages if we only wait. Unusually wet periods like the 1920s and 1990s will still continue to occur, but they will co-occur with higher temperatures that will increase water demand from plants, soil, snow, and humans.

Climate models and theory suggest that flow reductions would be more severe in the Southern portions of the Upper Colorado Basin affecting tributaries such as the San Juan, Dolores, and Gunnison more severely, with smaller impacts to more northerly tributaries such as the Yampa and Green [*Ayers et al*., 2016]. Such spatial distribution would provide additional water management challenges in that the more southerly basins have in general more people, infrastructure, and uses. Such a distribution would create new localized water supply shortages in addition to the overall basin-wide issues.

Other known threats to streamflows include the potential large scale loss of conifers [*Breshears et al*., 2005; *Adams et al*., 2009; *Allen et al*., 2010, 2015], and the impacts of dust on snow [*Painter et al*., 2010; *Deems et al*., 2013]. These factors along with the observed and projected temperature-induced Colorado River flow declines, the inability of many linked climate-hydrology models to simulate persistent droughts, and the increasing likelihood of hot drought and megadrought, all imply that future Colorado River water supply risk is high. It is imperative that decision-makers begin to consider seriously the policy implications of potential large-scale future flow declines. Stable twentieth century Colorado River flow regimes may not reoccur for many centuries—the time scale of climate system readjustment to the complete cessation of greenhouse gas emissions [*Solomon et al*., 2009; *Collins et al*., 2013].

The Colorado River declines do not stand alone as the only warming-related threat to Southwestern water supplies. The Rio Grande also has a grim prognosis [*Reclamation*, 2013; *Elias et al*., 2015]. The drought in California has garnered national attention, and multiple studies have strongly implicated increasing temperatures as a contributor to these woes [*Griffin and Anchukaitis*, 2014; *Belmecheri et al*., 2016; *Diffenbaugh et al*., 2015; *Mann and Gleick*, 2015; *Seager et al*., 2015a]. Southern California is particularly at risk, with a critical economy and a very large population, all coupled with a large reliance on both climate-threatened in-state, as well as Colorado River, water.

Adjusting to the new reality of rapid climate change will not be an easy or fast task; water management and water policy change slowly. The Colorado River is managed by a complex set of agreements, interstate compacts approved by Congress, international agreements, legislation, and court decrees set in place over the last 100 years [*Verburg*, 2011]. Most agreements were derived from twentieth century state-based negotiations with win/lose policy prescriptions that minimized basin-wide considerations of economic prosperity and potential harm [*Adler*, 2008]. None expressly includes climate change risk management, nor the provision for flow reductions that will be relentless on decadal timescales. New agreements often take years to put in place [*Department of Interior*, 2007]. The recently proposed structural deficit solution [*Central Arizona Project*, 2016], while important and laudable for the short term, will not solve the problem of large scale flow losses. With reduced water supplies, much will have to change in these agreements to address equity, economics, and social concerns on regional, state, basin-wide, and even national levels. Climate change threats to western water supplies are very real, and should prompt great concern and urgency among both water managers and the citizens of the Southwest.

TRANSCRIPT OF PROCEEDINGS

LARIMER COUNTY

BOARD OF COUNTY COMMISSIONERS

LAND USE HEARING

WEDNESDAY, MAY 16, 2018

THORNTON WATER PROJECT 1041, FILE #18-ZONE2305

COMMISSIONERS PRESENT:	STAFF PRESENT:
SEAN DOUGHERTY, CHAIRMAN	MATT LAFFERTY
JEFF JENSEN	DEBBIE JOHNSON
MINA COX	DENISE RUBALL
RAY CARRAWAY	ROBERT HELMICK
GARY GERARD	ROD BLOOMSTRUM
CURTIS MILLER	MARK PETERSON

SPEAKERS FROM THE AUDIENCE:

John Barth, Esq.	Sandy Hellser
Roberta Norman	Lynn Nichols
Mark Hyden	Jerry Palt
Scott Horack	Scott Glick
Elaine Spencer	Jim Camben
Dick Brouch/Brow	Patricia Corb/Mark Corb
Scarlet Sparkle Delia	Nancy Terry
Dennis Pierrero	Sean Shelly
Ryan Donovan	Christine Cracked
Karen Wagner	Jason Kinable
Karen Colavity	Gloria Edwards
Patricia Babbit	Lauren Sager
Harry Sheline	Mike McGlocklin
Penny Hillman	Teresa Rose
Doug McAllister	Nan Sollo
Robert Kitchell	Lucy Brickman
Janet Carabello	Rebecca Shelly
Georgia Locker	Rick Steadman

MR. DOUGHERTY: Good evening, ladies and gentlemen. We're going to go ahead and get started. I know we have a full house here, and I want to respect everybody's time.

Welcome to the May 16th, 2019 meeting of the Larimer County Planning Commission. It's a tradition of the Planning Commission to start off our meetings with the Pledge of Allegiance. I'd ask you to please rise and join us.

(Everyone stood and recited the Pledge.)

MS. SKAHAN: Thank you all very much.

My name is Sean Dougherty and I am the Chairman of the Planning Commission. Thank you all for coming tonight.

I've got a list of things I'm going to read through here, and then we will get started.

Your participation helps your Planning Commission understand the issues and impacts regarding the items before us. Copies of tonight's Agenda are on the wall by the door, please take one. And also, please mute your cell phones at this time.

The Planning Department staff provides us with a comprehensive package, almost 700 pages, of information about the projects and we did do a site visit today. Even so, we gain insight from the

information and viewpoints that you provide. Your input is welcomed and appreciated. We're here to listen to and carefully consider all information about this project.

If you wish to speak tonight, hopefully you've signed in out by one of the front doors and you will be recognized by me. When you come to the podium, please provide us with your name and spell any uncommon names, so the Record will be accurately reflected. We will start the clock after that.

We ask that you keep your comments relative to the land use of the matter being discussed, and we ask that you direct your comments to the members of the Commission.

We understand that the issues before us tonight are important to those involved and that those feelings and emotions can run high. We ask you to respectfully listen to everyone's presentations. You may or may not agree with them, but please do not interrupt with applause or other kinds of demonstrations.

In order for us to get through this hearing tonight in a timely fashion, I cannot allow demonstrations.

Please direct your comments to the Planning

Commission and the staff, not the Applicants or the other speakers.

I have some brief comments about the role of the Planning Commission for the audience, both those who are and those who are watching on TV.

The Planning Commission acts as an advisory board to the Larimer County Commissioners. We review and make recommendations on land use issues outside of town and city boundaries. Please note that the responsibility and authority to make the final decisions on these land use matters rests with our three elected County Commissioners.

The Planning Commission is the final decision-making body for location and extent reviews, as well as amendments to and approvals of the Larimer County Master Plan and its subplans.

The members of this Planning Commission are volunteers and I would like each member of the Commission to introduce him or herself, starting on my left.

MR. JENSEN: My name is Jeff Jensen. I've been on the Planning Commission almost eight years and I live in the City of Fort Collins.

MS. COX: My name is Mina Cox. I live west of Bertha and I've been on the Planning Commission for

15 years.

MR. DOUGHERTY: Commissioner Carraway?

MR. CARRAWAY: My name is Ray Carraway. I've been on the Commission about a year and I live in the Masonville area.

MR. GERARD: Gary Gerard, I've lived in the Larimer County my whole life, on the Planning Commission for about eight years. I live south of Loveland.

MR. MILLER: My name is Curtis Miller. I've been on the Commission for eight years, and I live in Loveland.

MR. DOUGHERTY: And again, I'm Sean Dougherty. This is my ninth year on the Planning Commission.

Mr. Lafferty, would you please introduce the staff in attendance?

MR. LAFFERTY: Yes, I'd be happy to.

My name is Matt Lafferty, I'm the principal planner with the Community Development Department, the planning division portion of that, and there are copies of the Agenda still remaining on the back wall here. Feel free to get a copy of that, if you want to follow along.

Also, as I stated a little bit earlier,

there's some assisted listening devices down here. If you're having trouble hearing the proceedings, feel free to come down and we'll help you those devices.

To my right tonight are two individuals. One of them is Debbie Johnson, the other is Denise Ruball (phonetic). They are also with the Community Development Department and it's their responsibility tonight to record tonight's proceedings on audiotape and videotape and then transcribe that information into a written record.

So it's important that you speak clearly and give us your information regarding your name when you approach the dias.

To my left is Rob Helmick. He's staff planner on this project with the Planning Department.

And to his left is Todd Bloomstrum (phonetic). He is the Public Works Director. We've got another service group. I can't remember what the name of it is.

And to his left is Mark Peterson, the Assistant County Engineer. To his left is -- not the assistant, the County Engineer, Rusty is out there.

And Leah Snyder (phonetic) is with the Health Department tonight.

And that'd be staff present for tonight's

proceedings.

MR. DOUGHERTY: Thank you, Mr. Lafferty.

All right. The first -- I want to remind everyone, if you have not -- if you want to speak tonight, and you have not yet signed up, please see one of our staff members that are in the lobby at both ends, actually waving in the back of the room.

If you don't sign up, I may not be able to call you to come up to speak, and we've still got a few minutes while we go through the first couple of items on our Agenda.

The first two items on our Agenda this evening allow public comment about land use matters that are not on our Agenda for the evening. A few points about this public comment: During this public input period, we cannot consider information on items that are scheduled or likely to be scheduled for a hearing in the future.

If your comments are about an item that is likely going to be in the future, we will ask you to please share your input at that time.

While this public comment is about items not on our Agenda, these items should pertain to land use. Public comment made on these items will likely not be addressed this evening, but will be forwarded to staff

for review and potential response at a later time.

Is there anyone in the audience who wishes to speak on any item having to do with the County Land Use Code that is not on the Agenda this evening?

(No audible response.)

MR. DOUGHERTY: Seeing none, Item 2 on our Agenda, is there anyone in the audience who wishes to speak concerning other relevant land use matters not on the Agenda?

(No audible response.)

MR. DOUGHERTY: All right. Our next item of business is the approval of the minutes from the April 18th, 2018 meeting. Are there any corrections or additions to the Minutes?

MR. JENSEN: I move that we accept the Minutes for the April 18th meeting.

MS. COX: Second.

MR. DOUGHERTY: I have a motion and a second. Thank you.

We will proceed with a voice vote of the Planning Commission. All in favor, please signify by saying, "Aye."

MANY VOICES: Aye.

MR. DOUGHERTY: Any opposed?

(No audible response.)

MR. DOUGHERTY: Excellent. Motion passes.

Typically there are two types of hearing items on our Agenda, consent items and full hearing items. Very simply, a consent item is an item that there is usually no dissension by any other party.

This evening we have a full hearing item; that is, a full hearing will be conducted to give the Planning Commissioners both sides of the application, so we can give an informed recommendation to the Board of County Commissioners. We will allow public comment on these after we have the full presentations.

I will let you know here in advance, because there are a lot of people signed up. If we get past 10:00 o'clock tonight and we still have a lot of public comment coming, likely we will just finish public comment and we will have to adjourned to tomorrow night to finish this. There will be no further public comment. If we get done earlier than that, though, we will hear this all the way through.

Our item tonight is the Thornton Water Project 1041. It is File No. 18-ZONE2305. Our staff contact is Rob Helmick. The description starts on page 1 and we will have brief presentations from Mr. Lafferty and Mr. Helmick.

Mr. Lafferty, please take it away.

MR. LAFFERTY: Thank you, Chairman Dougherty.

Matt Lafferty, again, with the Community Development Department.

As pre-occurred before tonight's meeting, I just wanted to spend just a couple of minutes before Rob's presentation to outline what we're here for tonight and what we're not here for tonight.

On the screen before you this evening is a section out of the Land Use Code for Larimer County that addresses areas of activities of state interest. This is referred to as "1041."

These -- this language comes to us via Section 2465.1-404 of the Colorado Revised Statutes. And those statutes authorize the county to decide as a county whether or not certain public utilities or other major factors like pipelines or gas lines, transmission lines, solar facilities, airports, things like that, are a matter that we want to evaluate as part of our process in the land use arena.

And through this process, Larimer County has adopted several of those things that are outlined by statute that we want to review. One such items is the siting and development of new domestic water or sewer transmission lines, that meet certain criterias, which is outlined in the language behind me on the screen.

I bring this up tonight because I wanted to be -- everybody to be aware that we are not allowed tonight to act on where the water comes from, where it goes, where it's drawn from, those are decisions that have been made by the State of Colorado as the part of their responsibilities through the Water Court and the Division of Water Resources.

So where the source of water comes from, how it gets here, and where it's drawn from, has already been resolved at the State level. As an analogy to that, I would like to use an example. If we were doing an electrical transmission line across the county, we would look it as a 1041 application. We would study for its impacts as it relates to impacts on the environment, visual impacts, impacts on the neighbor's proximity to the neighbors and what-not, to make sure that the issues could be mitigated in a way that everybody could accept that.

What we don't worry about is where the electricity comes from, how it's generated, or what causes it to be generated.

So tonight we are reviewing an application for a pipeline and where that pipeline will go and how the impacts associated with that pipeline should and will be mitigated in order for it to be a good feature

for Larimer County or whether it should not be in Larimer County.

And so with that precursor to tonight's proceedings, I would like to turn this over to Rob Helmick. He's the staff planner on this application and did the majority of the analysis and I'll let him have his presentation with you-all.

Thank you.

MR. HELMICK: Thanks, Matt.

Mr. Chairman, Rob Helmick for the Planning staff.

You have a voluminous packet. It runs over 600 pages of analysis and public comment, and in addition, you had provided to you the link to the electronic version of all of the application materials provided by the City of Thornton, which are these two monster notebooks. Mapping and other information, analysis and study of the pipeline and its components.

The City of Thornton has submitted this application for a 1041 application for the water line, as Mr. Lafferty pointed out. The specifics are 26 miles of pipeline in unincorporated Larimer County, pipeline of 48 inches in diameter. It's a welded steel pipe.

Pertinent facilities to that include a

40 million gallon per day pumping facility, a one million above-ground water tank, and other appurtenances to the system.

Associated with that are the acquisition of a 50-foot permit and 40-foot temporary construction easement. The pipeline is located out of the County Road right-of-way, or it would be located within a county road right-of-way.

City proposes this pipeline to move the water, which their rights were acquired in the '80s and subsequently, as Mr. Lafferty pointed out, received court approval to use the rights for municipal use. City of Thornton and the staff began some communication as early as 2/2014 with more discussions in 2015 and a pre-application conference when the application was done in May of 2016.

There were a variety of public outreaches done by the City of Thornton through 2016 and '17, and the application was originally submitted at the very end of 2017 and was scheduled for hearings in March and April of this year. Those hearings were deferred after the County stopped processing to request additional information from the City of Thornton with respect to certain issues associated with the Douglas Road corridor of this alignment.

The general alignment starts at Water Supply and Storage Reservoir No. 4 north of Douglas Road and heads east to the Larimer/Weld County line. There's a water tank proposed at that location and then the line runs straight down the alignment of Weld County 13, Larimer County 1, and exits Larimer County in Johnstown.

It also passes through, in doing that, a small piece of the City of Fort Collins and large areas of the towns of Timnith, Windsor, and Johnstown, as well as parts of unincorporated Weld County. Except for the Douglas Road corridor, which is defined as the current roadway right-of-way, the permanent corridor is anywhere from 500 feet to a quarter mile wide. This allowing for minimizing impacts to properties, structures, and resources, as the actual construction documents for such a project and right-of-way acquisition would occur, without requiring a return of process, unless there's a significant deviation from the approved corridor.

With respect to alternatives, the graphic here is out of the application materials and reflects the second round of alternative analysis that Thornton conducted. The first round was how do they get the water to Thornton; the second round was defining a

corridor which basically defines that from Water Supply and Storage Reservoir No. 4 to the City of Thornton's water treatment facilities just north of the City of Thornton.

These lines on the map represent an analysis that Thornton conducted prior to submitting the 1041 Application that identified corridors that they would evaluate. That evaluation was looking at both local input and desires, as well as dealing with minimizing impacts to right-of-ways, and minimizing impacts to water bodies and wetlands, by-passing geologic hazard areas, minimizing impacts to environmentally sensitive areas, and on.

And from that then came the proposed corridor, which is this map, (indicating), starting at Water Supply and Storage Reservoir No. 4, moving down Douglas Road to the intersection with Turnberry or Larimer County 11, then staying out of the roadway right-of-way on City of Thornton property going north to County Road 56, east on 56 to the railroad tracks, south on the railroad tracks a half-mile east, another mile-plus to the middle of property owned by Thornton, then north back to County Road 56. On County Road 56, then all the way to the Larimer/Weld County line, going north approximately a half mile to where the one

million gallon water tank would be located, and then straight down Weld 13, Larimer 1, all the way through Tinmouth, Windsor, Johnstown, to the Larimer/Weld County line in Johnstown at Weld County Road 50.

After some initial conversations with the Applicant and after the public meetings, there was some concern about alignment through neighborhoods. And the initial advice from staff back in 2014 and '15 was that we would not consider locating a pipeline like this in a county road right-of-way.

Subsequent to those conversations, internal policy changed and we advised Thornton that we would consider looking at a pipeline alignment within existing county road or future county road right-of-way, and from that then came this analysis of corridor linkages that Thornton analyzed. Those corridors took the original corridor which came out of Water Supply and Storage No. 4, which is at the center, left-hand side of your screen, and basically the initial proposal which comes straight out of that, buzz straight east along an alignment that would follow and then hook up with an alignment halfway between County Road 56 and 54 Douglas Road, and then across the interstate.

Because of some significant amount of neighbor concern, we asked Thornton to do an analysis

and so they analyzed a series of northern corridors, which are all these in yellow, which propose to come out of No. 4, go north, either outside or adjacent to or through Eagle Lake, get over to Highway 1, and then over to County Road 56 and then east. A series of central corridors, which are the ones in green here, which come right out of 4 and then go straight east, or they looked at three alignments along Douglas Road, north of, in and south of the right-of-way of Douglas Road.

They conducted a significant -- an extensive analysis of those alignments and their conclusions is -- and their application then became a out of 4 to a pump station outside of Reservoir No. 4, then along Douglas Road to Turnberry, thence north to County Road 56. So that is the application that we have reviewed for you this evening.

The pumping facility location is on a property north of Douglas Road. Starlight Drive is here, (indicating). No. 4 is here, (indicating). Eagle Lake is here, (indicating). There is a three-acre area that the City of Thornton has identified that they need to -- would like to acquire as the area necessary to facilitate the construction of their pumping facility.

If you go east of the County line, here is County Road 56. The pipeline runs north and the star represents the generalized location of where their proposed water tank might go, and this is a more -- a map from the application which identifies the proposed siting area for this one million gallon water tank.

So the 1041 Application has 14 criteria for review. You have our written analysis of those 14 criteria. I will hit the high points. I won't go over all of them, in trying to respect time.

The first is that the proposal is consistent with the master plan and applicable inter-Governmental Agreements. The analysis for the City of Thornton and our analysis of their analysis supports that the principles of the master plan are addressed and the request is consistent with the Larimer County Master Plan.

This route is through several growth management areas, as well as incorporated areas, which do not have GMAs. I would note that the Master Plan does contain a specific principle, which speaks to future transfers of water out of the County. Having been part of those conversations, I can tell you that this was adopted in part response to the actions of the City of Thornton in the '80s. But that the transfers

that the City of Thornton did, were essentially complete by the time these policies were adopted in the Master Plan.

As I talked about, the Applicant has presented reasonable siting and design alternatives and explained why no reasonable alternatives are available. From our perspective, they have done a thorough going analysis, both at the microscale for the Douglas Road corridor and as a more macro scale for the balance of the corridor, and analysis of alternatives, and the alternative presented by the City of Thornton as their preferred route does, in fact, meet the test of thorough analysis of alternatives for the proposal.

With respect to adopted County standards, the City of Thornton in Section 8 of the Code, specifically wetlands, the City of Thornton proposes to bore and avoid any interference in jurisdictional wetlands. They will obtain a nation-wide permit from the court to confirm that there are no jurisdictional wetland areas affected.

There are hazard areas, principally flood plain in Larimer County, on the Poudre, Big Thompson and Box Elder Creek. The City of Thornton on all three of these waterways proposed to bore and avoid any flood plain under these three river or stream corridors.

With respect to wildlife, the City of Thornton's environmental analysis for the preferred route identifies that there were possible conflicts for wildlife, both as listed were species of concern. Mitigation proposed includes avoidance, seasonal limitations and prohibition on certain activities. No other significant wildlife issues have been identified along the preferred route.

There may be, as a result of these mitigations, seasonal or other temporal restrictions to avoid conflicts with those listed species.

There are multiple irrigation facilities affected by this request. The Applicant will be required to cooperate and mitigate on any issues with any of those respective ditch companies. If they're required to bore, they will bore. If an open cut is permitted, they will do that. If our licenses or agreements Thornton required, the City of Thornton must acquire them.

They will need to obtain an air quality permit. They will need to obtain stormwater quality permits. That is the overview on standards.

The proposal will not have a significant adverse effect on, or will adequately mitigate significant adverse impacts on the land on which the

proposal is situated, and on lands adjacent.

Proposal, at least in the initial Douglas Road Corridor is located at a significantly developed area. There are some impacts to vegetation. And the impact in the project area, those impacts will be mitigated through the use of best management practices and do not constitute a significant impact on land affected or adjacent to the pipeline.

Issues with groundwater and drainage in the area of any bore or cut must be mitigated.

There are no historic or sites identified that are negatively affected by this proposal. There is not a significant negative impact to public health and safety. The proposal is not subject to significant risk from natural hazards, including flood, wildfire, or geologic hazard, principally because all the flood plain hazards, which are the principle ones associated with this request are to be bored and avoided.

Adequate public facilities are available for the request.

The Applicant will mitigate any construction impacts to county roads, bridges, and related facilities. Many of the conditions that you see in the staff report are those generated by the Engineering Department, specifically intended to address the

concerns of impacts through county roads and county facilities.

The benefit of the development outweighs losses of any natural resources or reduction of productivity of agricultural as a result of the proposed development.

There's no evidence that's been presented which would suggest the pipeline and its construction will cause a reduction in the productivity of the agricultural lands, nor are there any impacts to natural resources have been identified in the analysis.

The proposal demonstrates a reasonable balance between the costs of the Applicant to mitigate adverse impacts and the benefits achieved by such mitigation. We believe that the Applicant has presented adequate evidence to that respect.

The Applicant has presented a thorough analysis of the proposal and proposed alignment and corridor, our evaluation is that that avoids significant environmental issues as committed to disrupting the minimum -- causing the minimum disruption from this application or the construction activity.

So with respect to our analysis and findings, the findings are on the screen in front of you. We

find as a staff that the request is consistent with the Master Plan. It causes no significant impacts to natural manmade environment, is a reasonable alternative selected from several, identifies need of permits and permission and commits to obtain them, and it demonstrates a reasonable balance between costs to the Applicant to mitigate and any significant adverse impacts in the benefits.

There are now 30 conditions proposed, and those are available in the Agenda that went out to the public. The first is -- I'm not going to read them all, but the first is that everything that they have committed to in the application, or they commit to in the hearing process, is their commitments and the Applicant will be held to those commitments.

The approval designates a corridor along the alignment and deviations to accommodate, field issues will not affect the approval. Significant alterations to the route shall be evaluated by the County prior to commencing activity and may be subject to further review.

There are conditions related to roadway condition, roadway analysis, construction permits, permitting and access to all properties at all times for roadway access, that there's coordination with

emergency service providers and the school district to ensure that there is access and adequate school bus access at all times.

There is a pre-, during and post-project evaluation by Larimer County of any work done in a right-of-way.

The City acknowledges that the County Transportation Master Plan recognizes certain improvements along a portion of the proposed alignment west of County Road 11. We are not determined whether any roadway improvements will be implemented along Douglas Road within in the next five years. If the County proceeds with roadway improvements along Douglas Road, Thornton shall coordinate construction contracting administration with Larimer County.

One of the conditions is that irrespective of any action of the County, Thornton shall return the roadway -- any roadway that they are into, to pre-construction or better condition, which may mean resurfacing the roadway with an overlay throughout the construction area.

Patching -- spot-patching is not an acceptable alternative.

With respect to post-1041 permit action, a site plan review, building permits and development and

construction permits and access permits from Larimer County will be required for their various activities.

The pump station shall be designed to be consistent with the character of the neighborhood.

Water tank shall be located with the western slope of the hill on which it's proposed to be located, and designed in such a manner to avoid skylighting and minimize visual impacts to adjoining properties. All construction activities shall be coordinated with and respect all seasonal avoidance requirements established by the Colorado Department of Parks and Wildlife and the Fish and Wildlife -- US Fish and Wildlife Service.

And I've provided to you this evening, and to the Applicant, too, one, a modification to Condition 8, which adds air quality and noise to the parenthetical, "Thornton shall obtain and conduct, construct the activities in compliance with all required county, state and federal permits, including but not limited to" -- and we've added then, "air quality and noise" to that list that's in Condition 8.

Condition 30 from the -- speaks to, "Thornton shall be responsible for locating septic systems and wells and all associated distribution lines, servicing lots along the corridor prior to commencing any construction activities, septic systems must be" --

it's all there. "Identify, repair, do not damage or in fact, if there is damage, repair immediately."

That would conclude my comments. I'd be glad to answer questions, but I think Mr. Peterson has a presentation and then staff is available for any questions that the Commission may have.

MR. DOUGHERTY: All right. Thank you, Mr. Helmick.

Mr. Peterson, do you want to just continue on?

MR. PETERSON: Yes. Thank you.

Again, my name is Mark Peterson. I'm a County Engineer, and I was going to touch on some aspects of the pipeline that go into a little more detail, some aspects of both the pipeline, Douglas Road itself, and then just the touch on the more specific aspect of Thornton's Pipeline and Douglas Road.

So in terms of use of right-of-way corridors, certainly they are there primarily for use of roadway and transportation, but we have hundreds of miles of utilities in our rights-of-way even now as they exist, and that covers everything from water distribution, sanitary sewers, storm sewers, culverts and drainage, cross-culverts, gas, electric, other underground infrastructure and the like.

So it's a very broad range of public use -- public utility use of those rights of way.

In terms of specific requirements that Thornton has to meet, or any -- really, any user of our public right-of-way has to meet. First and foremost, they have to obtain right-of-way use permits. We issue about 300 permits a year for various activities within our public right-of-way.

We need to see engineer plans. As Rob has already noted, they need to address schedule, duration, work hours. Traffic control plans have to be developed and that has to include a detour plan, as appropriate. They have to address emergency response needs, local access needs, mail delivery, school bus access, and the like.

They have to meet construction and restoration requirements that are contained in the Larimer County design standards, whether those are urban roadways or rural roadways, as applicable.

And then as Rob mentioned, they have to restore roadway pavements or roadway surfaces to condition that's equivalent to or better than pre-project conditions.

And as already been touched on, they need to obtain all the necessary and appropriate other permits.

And part of our right-of-permit process, as well, is the Applicant warranties their repairs.

If you go to our Transportation Master Plan -- and I'm going to touch on kind of the Douglas Road Corridor. If you look on our Transportation Master Plan, we had both short-range capacity needs and long-range capacity needs identified in those plans. And this is a diagram showing the short-term capacity needs, and the different colored lines to note the type of improvement that's needed to convey traffic. Basically, it's traffic capacity.

If we then look at longer term needs, for purposes of our Transportation Master Plan, long term went out to the year 2040 and, in fact, the Planning Commission just adopted an updated Transportation Plan this last year. So again, what it identifies is needs to pave unpaved roads, or perhaps widen an existing road, add shoulders to it. Go to a three-lane section in some cases, or even a four-lane roadway in the future.

We zoom in on the Master Plan, this area that's highlighted in orange, is what was identified for a segment of Douglas Road. It's basically a segment running from County Road 17 on the west to State Highway 1.

On the east, and it identified that at some point in the future, in the long-term future, improvements would be needed from strictly a capacity standpoint on this road segment, and tht was to accommodate future estimates of traffic growth. And again, it's very much an estimate of traffic growth over this long-term horizon. We can't say exactly how traffic will grow, because it's largely a function of both development and growth in the region and use of the roadways by traffic coming from different areas in the county.

Also contained in the Transportation Master Plan was traffic counts, and so this compares 2016 counts relative to 2040 projections -- and again, the different colors denote different ranges of traffic -- average daily traffic on each of these road segments. Probably the thing to note is you're going to see over the next 20-plus years, you're going to see significant growth in traffic on the various road segments throughout the County and so red obviously is denoting the highest ranges of growth, but you can kind of see a lot of roads converting from a 400-5,000 range going into the 5,000 to 10,000, or 10,000-plus ranges of traffic.

And again, this is Douglas Road shown in the

orange.

If you look on our page network, again Douglas Road is also known as County Road 54. It's one of the few kind of east/west connections that actually extend west of State Highway 1, so the whole series of irrigation reservoirs and lakes that we have in this part of the County really affect or influence where you can make transportation connections, and so Douglas Road is one of those that can pick up traffic from 17 and west of State Highway 1, and convey it towards I-25. Certainly there's no direct connection to I-25, but there is the Mountain Vista Interchange on I-25 to the south.

In terms of road function, Douglas Road is currently classified as an "arterial roadway," meaning its primary function is mobility. The thing to note is that Larimer County has a five-year capital improvement plan and it identifies funded projects through the -- currently through the year 2022.

We do have signalization of State Highway 1 and Douglas Road. That's part of the current five-year capital improvements program. It's a project -- a cooperative project basically between Larimer County, the Colorado Department of Transportation, and the City of Fort Collins. Right now it's grant-funded in large

part and we've got money to start the design in 2019 and construction in 2020, but the thing I would note is that no other improvements to Douglas Road are included in the current capital improvements program.

Typical road elements: If you start looking at what might be needed in the future and Douglas Road is you're apt to maintain a travel lane in each direction. We've typically looked. It would have a rural section, generally with roadside drainage. Consideration certainly is widen, pave shoulders to support bicyclists, pedestrians, and the like.

We've looked at turn lanes, whether they be continuous or localized, and those are appropriate for both safety and capacity. And then you would be looking to extend and reconstruct drainage and irrigation crossings as part of any type of future capital improvement program that would be done on this roadway.

So when we held a public meeting in January, we came forward. We -- at a very conceptual level, we identified what might be required in terms of pavement width and right-of-way width associated with a three-lane, paved roadway, with eight-foot shoulders. One of those lanes is a center -- continuous center turn lane. And that was looking at improvements going from County

Road 17 or Shields, over to Turnberry.

We got a fair amount of public comment. We tried to listen to what people were telling us, and so we took another look at what, again, might be done at a conceptual level for improvement project, the Douglas Road. So we basically looked at six-foot shoulders along the entire length of that roadway, again, to better support bike and ped use, as well as traffic safety. Either as some nominal increase in road capacity that comes about through widened shoulders, as well.

So when we go to a six-foot shoulder situation, there's basically no improvements that are required for the stretch of road between County Road 13 and Turnberry. That roadway segment already has six-foot shoulders that were constructed back when development occurred in Hearthfire (phonetic) through the City of Fort Collins.

And we looked from a safety need, where we've got driveway access locations and the need for center continuous turn lanes, and really that extends from Swan Lane to State Highway 1. That's where we've got most existing development, a lot of driveway access points, as well.

And then going beyond that, we would just

look at widened shoulders along the remaining portions of the roadway in this reach.

We put that information out on the website. This is an example of a plan view that was also shown that's available out on the web that identifies existing right-of-way widths and how the lane configuration would lay out. Again, this is somewhat conceptual in nature. We certainly have not gone through a full design process.

And these are examples of roadway cross-sections, so the existing roadway cross-section is shown at the top and really the only change in something like this is where we've got -- where we have two- to six-foot shoulders, now we would have six-foot shoulders in all those areas where we would be staying with the two-lane section.

This is a typical example of a road with six-foot shoulders. This is Boyd Lake Avenue that was just constructed last year.

And then if you looked at that segment that would have -- potentially have a center continuous turn lane, that's really what you're looking at in cross-sectional view there, and this is an example of Shield Street.

North of Apoota River (phonetic), County,

again, did an improvement project on that roadway a few years back and put in a center continuous turn lane on that roadway.

So again, from a road perspective, along Douglas the current right-of-way width varies. It's anywhere from 60 to 100 feet in width. We only acquire -- if we go to do a road project of any type, we're only to go and acquire the right-of-way deeded for that specific road improvement project.

If you were talking about the portion that had a center continuous turn lane, with a reduced shoulder to six-foot on each side, the total width needed would be around 80 feet. Again, this needs to be qualified by the fact that this is assuming you have a roadside barrow ditch on each side and what actually is needed and what the actual topography is on either side of the road would influence those actual catch-points and required right-of-way widths.

If you then take the areas where you wouldn't have a center continuous turn lane, you obviously eliminate that 12 feet from the width of the road platform.

In terms of the pipeline corridor, we went back to the City of Thornton and asked them do additional data collection, go out and locate the

utilities that were out there currently in existence, to locate fences and other features to identify property lines and right-of-way limits, and they provided those exhibits.

They have submitted information to us that identifies that the proposed pipeline and the associated work limits can be located within the existing right-of-way along Douglas Road, as it currently exists.

That's the extent of my presentation.

MR. DOUGHERTY: Thank you, Mr. Peterson.

Do the Planning Commissioners have any questions for staff?

Commissioner Jensen.

MR. JENSEN: Mr. Helmick, correct me if I'm wrong. I thought I heard you say that we had 14 review criteria. Our package shows 12.

Did we miss a couple, or did you really mean 12?

MR. HELMICK: I think I really meant 12.

MR. JENSEN: Okay. Also on No. 8 of the criteria that you listed, I caught what you said when we add -- that you added air quality permitting to that. You said one more, and I missed that. Can you tell me what that is, please?

MR. HELMICK: Noise.

MR. JENSEN: Noise, okay, thank you.

MR. DOUGHERTY: Commissioner Carraway?

MR. CARRAWAY: Yeah, I just had a question for Mr. Lafferty.

Matt, this may be a legal issue, and I may be asking for more than what you're able to help me understand here, but my understanding in regard to state law is that it does give the counties a tremendous amount of discretion in regard to the 1041 process. And that mitigation that does not directly relate to the project itself, is something that can be required by the County.

Is that your understanding, or am I asking for just way too much of a legal issue here?

MR. LAFFERTY: That's a legal issue, but I think that any criteria that you have to -- anything mitigation that you require as part of an application has to have a rational nexus to what's being proposed. If there's no nexus between what's being proposed and what you're using to mitigate, then you're acting outside of the limits of what the application is about.

MR. DOUGHERTY: Commissioner Cox?

MS. COX: Mr. Peterson, how long -- you mentioned warranties, the very last line there. How

long are the warranties for and what are those warranties?

MR. PETERSON: It's basically about restoration of the surface of the roadway, you know, that we don't see settlement or failure of the pavement. It's two years is what's in our right-of-way permit.

MS. COX: And then one other question: On the 1041, if Thornton wants to come back in and add more pipelines, they would have to go through another 1041 process; is that correct? 1041 only allows for repair, replacement, but not necessarily additional pipelines within their current pipeline corridor that they would be putting in.

MR. PETERSON: They get what they asked for. They don't get anything more. So if they want another pipeline or another major facility, it's a whole new application.

MS. COX: Thank you.

MR. DOUGHERTY: Other questions for staff?

(No audible response.)

MR. DOUGHERTY: I have a question for Mr. Lafferty, I believe, or actually it might be for Mr. Helmick.

Earlier there was a comment about easements

and either a 50-foot easement or 40-foot construction easement. Is that 50-foot easement only if the pipeline as proposed would be outside of the right-of-way of the road?

MR. LAFFERTY: That's correct.

MR. DOUGHERTY: Okay. I just wanted to clarify that. Thank you.

Other questions for staff?

Yes, Commissioner Jensen.

MR. JENSEN: On an arterial road, is a two-inch overlay normally the way that is paved, or would it be more than that normally?

MR. LAFFERTY: Well, so what they have to do as part of their project is they will have to restore any disturbed road portions like where they complete excavate through the pavement, they will have to do significant patching, and there's standard on the patch thickness. I don't have that number off the top of my head, but it's a fairly considerable thickness of asphalt on a arterial roadway, and then we're basically saying that because we4 believe there is going to be enough disturbance and damage to the road and enough disturbed areas that we want the entire roadway with a leveling course and a two-inch overlay over it.

MR. JENSEN: Okay.

MR. LAFFERTY: When it's all said and done. So it's not just a two-inch overlay by itself. It's patching and a two-inch overlay.

MR. JENSEN: Okay. That was my question, so thank you.

MR. DOUGHERTY: Just to continue along with that, Mr. Peterson, Item No. 4 on our -- on the recommendation conditions talks about stabilizing an asphalt patching, all pavement areas disturbed or damaged during the pipeline installation, Item No. 5 says due to the large extent of pavement removal required, they're responsible for leveling course and two-inch thick asphalt overlay.

Is it either/or? I thought it was only the two-inch?

MR. PETERSON: No, they have to fully stabilize and patch all areas that are excavated and disturbed as a result of pipeline construction. In addition to that, they're putting a two-inch overlay -- leveling course and two-inch overlay over the entire width of the existing roadway.

MR. DOUGHERTY: So on top of the patches?

MR. PETERSON: Correct.

MR. DOUGHERTY: Okay. Thank you. I just wanted to --

MR. PETERSON: So that we get a new continuous road surface over the existing road.

MR. DOUGHERTY: Thank you.

Any other questions for staff?

(No audible response.)

MR. DOUGHERTY: Okay. The City of Thornton is our Applicant and I would like to invite their representatives up to give their presentation.

And please state your name for us.

MR. KOLEBER: Mr. Chairman, Members of the Planning Commission, my name is Mark Koleber, K-O-L-E-B-E-R. It's also up on the screen.

I am the Thornton Water Project Director for the City, and I'd like to provide you with some information about the Thornton Water Project to highlight some of the areas of our 1041 permit application.

I'd like to start with the project overview. The Thornton Water Project is proposed in the Larimer County 1041 Permit Application is for delivery of the water associated with the Water Supply and Storage Company and Jackson Ditch Company shares, which have been diverted from the Poudre River since the late 1800s. These shares were acquired from willing sellers by the City of Thornton in the 1980s.

There will be no change in the point of diversion of these shares and delivery of this water through the pipeline will not result in any additional water being diverted from the Poudre.

One of the first things our City Council did before we started introducing the project to the public, was to establish the mission, vision, values, and guiding principles for staff as we worked on this project. These include open communication and transparency about the project, collaborating with the communities along the pipeline route, and a commitment to being a good neighbor and good steward, for those that are affected by our project, as well as the Thornton residents.

Like the cities across Northern Colorado, Thornton is growing. And the City is working to achieve what all Municipal water suppliers strive for, and that's to provide a reliable water supply to current and future residents.

In addition, Thornton Water Project will help address issues with some of our current water supplies so that we can meet the expectation we all for our water. A safe quality drinking water supply when we turn on the tap.

The Thornton Water Project, along with

Thornton's other sources, will meet the City's projected municipal needs through 2065.

Mr. Helmick covered some of this, but I'd like to cover some of the detail and as the Thornton Water Project as proposed in the 1041 Application is a result of a series of evaluations about how to deliver the City's water. I'll cover these steps in more detail, but in general there were four steps to get to the current proposed project configuration.

We started with looking at different concepts for how to deliver the water and determined that a pipeline was a concept that met our project needs.

Next, we looked at where that pipeline could go through the counties and towns that were between the Water Supply and Storage Company Reservoirs in the City of Thornton.

We further refined those potential routes by looking at ten alternative alignments in the area north of Fort Collins.

And finally, we looked in detail at Douglas Road to make sure that alignment would work.

The delivery concepts we looked at are shown here on this slide. We looked at a pipeline from the Water Supply and Storage Company Reservoirs to Thornton and that's what's before you tonight. We also looked

at running the water down the Poudre to Windsor and then in a pipeline to Thornton. We looked at trading the water through the CBT System, over to Horsetooth and Carter and on down, and a pipeline out of Carter Lake to Thornton. And we looked at running the water down the Poudre River to the South Platte, and then operating the water as exchange to get the water into Thornton's system on Clear Creek in the South Platte River.

Our delivery concept evaluation concluded that the pipeline from the Water Supply and Storage Company Reservoirs is the only one of these concepts that can meet the purpose and need of our project.

And there are a few other things that need to be considered, such as Thornton's decree currently only allows these water rights to be diverted to the historical point of diversion, which is the Larimer County Canal.

Continuing to divert at the Larimer County Canal maintains the ability for Thornton to use the water storage associated with the Water Supply and Storage Company Reservoirs, and storage is a critical component of any municipal water supply system.

The Poudre River downstream of Shields Street isn't classified by the State for water supply uses, so

the river downstream of Fort Collins, where some would like us to take our water, doesn't have their protections needed to use that source for a drinking water supply.

Using a pipeline also avoids the water lost that would be associated with running water down the river, and again, it's important to note that these flows have been diverted in to the Larimer County Canal for over 100 years, so the Thornton Water Project won't change the amount of water flowing through Fort Collins.

So once we had determined that the pipeline was the only delivery concept that met the project needs, we started working with local governments, utilities, districts, and others, to identify where the pipeline should go.

Mr. Helmick covered some of this: We started with a corridor that was six miles wide, east of I-25, three miles tall north of Fort Collins. We went out and we talked to the communities, counties and towns, and identified where would be the good routes and the map that Mr. Helmick already showed, and I also show up here, was this first round of our outreach. We went back again to come to the conclusion of our corridor, and Mr. Helmick has shown that.

And then to ensure we could provide information to residents along the preferred corridor, we set up a project-specific website, as well as an email address, and phone number where people could send us comments and get questions -- or get answers for their questions.

Through the website, you could also sign up to receive project updates. To-date we've had over 15,000 visits to our website. We sent out 11 project update newsletters, and we have 374 people signed up to receive our newsletters.

This digital outreach was a key component of our plan to reach out to residents that might be affected by our project.

The overall outreach plan was discussed with the Larimer County staff, who concurred that the additional outreach would be helpful in ensuring residents understood the project.

In late 2016, we held four open houses along the proposed I-plan corridor to introduce the public to the project and to start gathering feeDVAck that we would need for our project. We held meetings in Fort Collins, Windsor, Johnstown and Firestone.

For these open houses, any property owner within 500 feet of our initially proposed quarter to

half-mile corridor was mailed an invitation to our open houses. Thornton sent out invitations to 1272 property owners, including 849 property owners in Larimer County.

A reminder invitation was sent out after our first two open houses, letting people know that were still two more open houses, if they wanted to get information about our project.

There were 146 people that signed up at these open houses, and there were some that attended, but didn't sign in.

Part of our sign-in included the opportunity to sign up for our email project updates, and attendees were provided with cards to submit comments on our project.

We presented information about the proposed project corridor, general construction sequences, and the City's land acquisition process, as well as an overview of the project and some Thornton history associated with the project. The open house resulted in many good, one-on-one interactions with members of our project team and we received great feeDVAck on what we should take into consideration when we identify a specific route for the pipeline.

Because there have been some questions about

open house notifications, specifically along Douglas Road, I wanted to show the area that we used for mailing open house invitations. Invitations were mailed to the owner of any property that included area within the redline on this map, and we used the Larimer County Assessor's information for mailing addresses for the property owners.

As a follow-up to the open houses, we received several requests to meet with property owners and HOAs. We attended HOA meetings, as well as meetings with small groups of residents. We received additional area-specific feeDVAck from residents at these meetings, and I think it's important to point out that we attended any meeting that we were invited to.

It didn't click.

(Adjusting equipment.)

MR. KOLEBER: Thank you.

Subsequent to the open houses, Larimer County staff requested that we look at alternative routes, including use of
County Road right-of-way and Mr. Helmick covered some of the discussion, as well.

We looked at ten alternative routes, removing from the Water Supply and Storage Company Reservoirs to the northeast corner of a Thornton-owned farm, which on

this map is this green hatched area, and so we own -- this is Turnberry and this is Road 56. This green hatch area is a Thornton-owned farm. And from there, the corridor continues east.

Our analysis used criteria that addressed the concerns we heard during the open houses, and other meetings with residents and from Larimer County staff. We used criteria that took into consideration both the construction of the project, as well the ongoing operation of the project. The route in Douglas Road had the overall best score.

Thornton held a community meeting to present the results from the alternatives analysis and provide information on the Douglas Road alignment. Thornton sent invitations to property owners within the redline shown on the map, as well as emailed invitations to those that had signed up for our project updates. 153 people attended that meeting.

In addition, Larimer County staff presented information about the Douglas Road transportation needs at this meeting.

Because there were some concerns about the 500-foot wide corridor along Douglas Road, that the City had included in its initial 1041 Permit Application, Larimer County requested that the City

confirm that the pipeline could, indeed, be constructed within the existing Douglas Road right-of-way, as proposed by Thornton.

Mr. Helmick and Mr. Peterson have already shown that information that confirmed that we were able to build entirely within the Douglas Road right-of-way.

This map shows the corridor that Thornton proposes for construction of a Thornton Water Project. The 1041 Permit Application only covers those areas of unincorporated Larimer County along the proposed pipeline route. The pipeline construction in the incorporated areas of Timoth, Windsor, Johnstown, will be permitted through those jurisdictions.

Thornton is requesting that Larimer County approve a corridor for the Thornton Water Project because it would allow Thornton the ability to work with the property owners, to find a suitable location for the pipeline on their property, to adjust the pipeline location to accommodate existing utilities or other conditions, and allow Thornton to work with property owners to find the best fit for a pipeline route through planned developments.

The corridor does not provide for future construction of additional pipelines. And once construction is complete, the corridor will no longer

apply and Thornton will have only the easements that it does acquire.

Any future pipeline installation by Thornton 50 or more years down the road, would require a 1041-type permit under the regulations in effect at that time.

Mr. Helmick has already covered the source water pumping station. I won't go into any more detail on that.

Then along with the conditions of approval that the County staff have recommended as part of the permit, Thornton has proposed 145 mitigation measures and commitments to ensure the Thornton Water Project impacts are minimized or prevented.

Outside areas where construction will occur in County Road right-of-way, Thornton will acquire easements for construction of the pipeline. Thornton will respectfully work with property owners and provide just compensation for any easements that the City acquires.

Thornton will work with the property owners to locate the easements where the impact can be minimized.

The property owner will be able to use the surface over the pipeline once construction is

complete.

In the area where a pipeline is constructed, the property and any improvements, like fences or landscaping will be restored after construction. And our goal is to negotiate for all easements that we'll need to acquire and will only use eminent domain when all reasonable alternatives have been exhausted.

Once construction in the initial property restoration is done, Thornton will monitor the areas and continue restoration activities until the area is restored to the property owner's satisfaction.

As this timeline shows, we're currently in the permitting and land acquisition stage of the project. We'll start design this year and we'll start construction in 2019. The goal is to have the project online delivering water to Thornton's treatment plants by 2025.

For construction along Douglas Road, the design will start shortly after affirmative approval and construction would follow starting in mid-2020.

The final paving would occur in 2021 after an approximate 12-14 months pipeline construction period.

Thank you for your time this evening, and I'd be happy to answer any questions.

MR. DOUGHERTY: Thank you, Mr. Koleber.

Are there any questions for Mr. Koleber from the Planning Commissioners?

Commissioner Carraway.

MR. CARRAWAY: Yeah, just in terms of my understanding of some of the concerns, obviously there's the concern of inconvenience and the noise and the traffic issues and all that, and you know, that's obviously pretty obvious to everybody. But what I haven't heard mention of there's also concerns that I've heard just relating to this whole issue of buy and dry, and the whole issue of just the health of the Poudre River.

Are those issues, the buy and dry issues, and just the basic health of the Poudre River -- and by the way, I totally get that you're not taking any more water out of the river than what's been diverted previously, but my question is: Are these latter two issues that I'm mentioning, the buy and dry issue, health of the Poudre River, were those given any thought? Were there any discussions about ways that those could be addressed in a creative, positive manner, that just brings -- you know, that tries to bring the various parties together to just talk about those very important issues?

MR. KOLEBER: Absolutely. We've been

committed since the mid-1980s to being a good steward of our properties. Once we've bought those properties, we've only taken those out of production that we need for the short-term water supply for the City of Thornton. The remainder will be remained -- or be retained in irrigated agriculture until we need that water down in the City.

When those properties are taken out of irrigated agricultural production, we go through an extensive effort to make sure that they are converted into a self-sustaining dry land grass cover so that there are not weed problems, dust problems, or anything else. And we work with the local farmers to cut the hay on those properties, lease them for grazing, or whatever we can do to keep them in the agricultural community.

We are, in essence from the mid-1980s until we'll need the last amount of water, it'll be a 20-year transition from when we bought those farms until we'll need all the water off of those farms. So we're being a good steward in the meantime so the buy and dry aspect of that, we believe we're managing in a very good fashion.

As far as the Poudre River -- I'm sorry. Did you want to?

MR. CARRAWAY: Well, just real quick on that.

MR. KOLEBER: Sure.

MR. CARRAWAY: Have you explored, for example, some type of a creative water-sharing-type mechanism where you would have a situation where the agricultural lands wouldn't be completely dried up, that they could use water for ag purposes in certain years, other years the water goes to Thornton?

MR. KOLEBER: We have considered that. Our decree does not allow it. The Water Court specifically prohibited us from moving water on and off our properties. Once we have it off, we're not allowed to put our water back on. We can, however -- and we've had some discussions with others about bringing other water onto those farms, particularly if they're a very high producing, very productive farm, we'd like to get water back on those. But it can't be the water that we have that's going to Thornton.

To your second point, we have had lots of -- very good constructive conversations with -- the Poudre runs through a group. I'm a member of that group. And we have looked at ideas like as we transition our farms from irrigated to non-irrigated, there's about a 7-year time period there where you can't put the water on the farms, but we can't take it to Thornton. That would be

a great opportunity to try to work with folks to get the water going into the river.

We're working and our attorneys are working on the Poudre River odd plan, which would allow water to be donated for in-stream purposes on the Poudre to help the environment along the Poudre. That's something we're committed to, we're working hard at, and we hope that we can be successful with.

MR. CARRAWAY: Yeah, just real quick follow-up on that last point, so what you're talking about then is the potential of something that would help with base flows on the Poudre, and -- but that I understand, that's something that you're talking about, you're having discussions about, but that's not part of the mitigation that you have laid out for this process?

MR. KOLEBER: It's not because right now it's not legally available to us.

MR. CARRAWAY: Okay.

MR. KOLEBER: We still have to go through the Water Court process to get that augmentation plan approved, so that we can use that kind of a mechanism.

MR. CARRAWAY: Okay. And just one last question, just in regard to the ditch system, you know, I've had discussions with people about this, and people that are much more knowledgeable about water issues

than I am, and they were just questioning whether or not the current ditch structure is sufficient to where if it were improved in an appropriate manner, that you could actually get the water over to Weld County through the ditch system without a pipeline. Is that something that has been explored at all?

MR. KOLEBER: Well, that could work, except the problem for Thornton is that that would then bypass the Water Supply and Storage Company Reservoirs, and those reservoirs are a key component of managing a water supply because the water comes off during a few months during the summer. We have to stage it for delivery across the entire year and then from year-to-year when we have dry years and wet years. So that Water Supply and Storage Company Reservoir storage needs to be in line for our pipeline.

MR. CARRAWAY: Okay. All right. Thanks.

MR. DOUGHERTY: If I may, I'd like to keep us on track here. We need to be asking questions about the actual 1041 and the pipeline application itself.

Commissioner Jensen?

MR. JENSEN: You mentioned, Mr. Koleber, that if you were to pull the water -- that you could not pull the water off the lower Poudre because protections are not in place on the lower Poudre to allow that to

be a municipal water supply.

Did I quote you correctly, or?

MR. KOLEBER: That's one of a number of reasons, yes.

MR. JENSEN: Okay. What are the mitigations that would have to have been done or would need to be done on the Poudre River through town if that was going to be a water supply conveyance to be able to pull it further downstream?

MR. KOLEBER: I'm speculating that it would need to be advanced waste water treatment, storm water treatment along the way, storm water detention, that's not really something we looked at.

MR. JENSEN: Okay.

MR. DOUGHERTY: Any other questions for Mr. Koleber?

(No audible response.)

MR. DOUGHERTY: And just to clarify, the reason you did not look at that is because that is not allowed per your water rights, correct?

MR. KOLEBER: That and a number of reasons.

MR. DOUGHERTY: All right.

MR. KOLEBER: It's not allowed by the water rights, the quality degrades, the storage isn't available. You lose about 9 percent of your water by

running 18 miles down the river. There's a lot of different reasons why that doesn't work to meet the purpose and need of our project.

MR. DOUGHERTY: Okay. And then one more clarification, you will not be diverting any more or any less water out of the Poudre River by utilizing this pipeline; is that correct?

MR. KOLEBER: We only will be diverting the water associated with our shares, which is limited by historical future use that those water rights will divert no more than what those shares deliver.

MR. DOUGHERTY: All right. Any other questions for Mr. Koleber?

(No audible response.)

MR. DOUGHERTY: Okay. Mr. Koleber, thank you very much.

MR. KOLEBER: Thank you.

MR. DOUGHERTY: At this time we're going to take a quick 10-minute break, then we're going to jump right into public comment. And I thank you-all very much.

We'll be right back.

(Recess taken.)

MR. DOUGHERTY: Okay. Ladies, ladies and gentlemen, we are coming back to order and if you guys

are talking, the people at home can't hear us. I really want to respect your time. I apologize for having to take the break, but we've been out since 2:30 today in a hot van and then we had to rehydrate and well, you know what happens.

So we are going to try something a little bit different here on our speakers. A number of you have spoken up and signed up to be able to yield your time to someone else. We are going to start with John Barth and then when John is done, he's had enough people yield to him. He's got 15 minutes.

After that, I'm going to go through my list here and I'm going to call three people at a time so that we have seats up front here.

Again, I really don't want this to go too late for you guys, as well as for us.

Additionally, one other thing I forgot to mention earlier, if we go past 10:00 o'clock and if any of you go outside one of the doors to the building, please make sure you have somebody inside to let you back in. The door will lock behind you. I don't have any control over that.

Additionally, please remember we can either approve or deny the application. We can't change where the water comes in or goes out.

I would ask also that you speak to this application, not to any other perspective possibilities that are not a part of this application. That won't help us to make a recommendation.

John, the floor is yours.

MR. BARTH: Thank you very much. My name is John Barth. I'm here tonight appearing as an attorney on behalf of the No Pipe Dream Association. Thank you for the opportunity to present a group presentation tonight.

The No Pipe Dream Association submitted a lengthy comment letter with exhibits opposing Thornton's 1041 Application. While I don't have the time tonight to address all the issues in our comment letter, I will address some of those issues and the most important ones. However, we reserve all arguments in our comment letter even if I'm unable to address those tonight.

Tonight I'm going to unleash the elephant in the room. The elephant in the room is whether this Commission is going to comply with the requirements of 1041 and require Thornton to submit a comprehensive application for all aspects of the Thornton Northern Project, which includes return flow pipelines, additional pump stations, a separate water delivery

pipeline or whether this Commission is going to ignore what they know about the full extent of this project and allow Thornton to segment this project into small little bites, thereby minimizing the impact of each little project that it submits.

In addition to presenting the law on what 1041 requires, we also are going present a viable financial and technically feasible alternative to Thornton's Northern Project, and that's namely to move the point of withdraw of water from the Poudre east of Old Town Fort Collins. Not only is this a better alternative for the Poudre River, it also has a greater chance of community acceptance within Larimer County and thus, a higher probability of success for the City of Thornton.

Finally, while we are asking the Commission to recommend denial of the 1041 Application, if the Commission does recommend approval, we're going to ask for additional significant conditions to be included in any 1041 approval, and that would be to limit forever the scope of the Thornton Northern Project to what their 1041 Application contains, and that's the single pipeline.

I encourage you to ask questions, but I ask that you hold your questions until the end of my

presentation.

So the Thornton Northern Project is a large water delivery project, including two parallel pipelines, water delivery pipelines to Thornton, multiple pump stations, and return flow pipelines. The TNP, or Thornton Northern Project, would deliver clean water from the Cache la Poudre River in Larimer County to Thornton and pipe more polluted water from the South Platte River into Larimer County as return flows.

"The components of Thornton's water supply and Thornton's water system are operating together as an integrated project or system," and that quote is straight out of the 2015 Water Court decision.

Here's a map of the Thornton Northern Project that shows two delivery pipelines to Thornton, not one. Return flow pipelines where they take water out of the South Platte and bring it into Larimer County -- and again, this is more polluted water than is in the Cache la Poudre, and they will deliver that polluted water into your watersheds in Larimer County.

And in addition, there are pump stations throughout here for the return flow pipelines and additional pump stations for the second water pipeline.

Thornton's 1041 Application is a small sub-component of the larger Thornton Northern Project. The

Thornton water pipeline application only addresses a single water pipeline frm the WSSC Reservoir to Thornton. No other Thornton Northern Project structures are included in the 1041 Application.

While the TNP is a single integrated system, it's 1041 Application is not. What structures are excluded from the 1041 Application? First just to start, the pump station at WSSC Reservoir No. 4, they're going to do that through site plan and not through 1041, so the impacts of that have not been fully evaluated.

The second parallel waterpipeline which could require takings and eminent domain of many of the people's property that are sitting here today, the return flow pipelines from the South Platte River to Larimer County watersheds, additional pump stations, these impacts from what remains from the Thornton Northern Project are going to be far exceeding the significance of impacts of the current 1041 Application.

So impacts are excluded from the 1041 Application? Impacts to property owners from the pump station, noise pollution; zoning, which is a major issue; and traffic. Impacts to property owners from the second parallel water line, as I mentioned eminent

domain is likely. Impacts to property owners from the return flow pipelines. Impacts to water quality from highly polluted water from the South Platte River return flows into Larimer County and impacts to agricultural lands like Commissioner Carraway was asking about the drying up. This is something that should be evaluated and this permit application simply is not.

Here is a picture of Douglas Road and some of the opposition to this project and application.

Let's talk about what the purpose of the 1041 law is. The 1041 law, the purpose is to look at all impacts from large projects at one time, not to segment them out. Thornton's permitting strategy is to avoid a comprehensive assessment of all impacts by segmenting the TNP into smaller projects, thereby denying Larimer County and its citizens the comprehensive impact analysis guaranteed by the 1041 law.

Here is what the 1041 says. This first quote is right from the Colorado Supreme Court, the highest court in the state, and is an en banc decision, which means all of the justices participated in that. And what they found is that 1041 allows local governments to supervise land use which may have an impact on the people of Colorado beyond the immediate scope of the

land use project. That's the whole purpose here, folks.

In adopting the 1041 statute, the Colorado Legislature recognized that there's inadequate information on land use that's lacking to decision-makers, just like you. Here we are, inadequate information. We've got a segment of the entire project that's being submitted to you and you don't know anything about the impacts to the rest of the project.

The 1041 Application violates both the letter and spirit of the 1041 law by denying information on impacts to Larimer County beyond the immediate scope of its segmented application.

What are Thornton's responses to this? Thornton argues that it can't present all information now because it doesn't know which or what structures will be constructed or when.

Well, as you saw from the map, which was part of the Water Court decision, they know what the additional structures are. They know there's going to need to be another pipeline. They know there are going to be additional pump stations. They submitted that map to the Water Court to get approval for this project. They know they're going to need those things, but they're trying to tell you, oh, we have no idea

when it's going to happen.

You need to tell them to submit that information now. This is your only chance to get that information. Once they get their toe in the door --

(Applause.)

MR. DOUGHERTY: Ladies and gentlemen, I cannot have outbursts. I will clear the room if I have outbursts.

Thank you.

MR. BARTH: -- and the way to respond to this is simply deny the permit application and tell them to come back with a complete application to satisfy the requirements of 1041.

Thornton also says that this is the only water supply addition to their system until 2065; however, documents on their own website seem to appear to show something different.

This is from Thornton's Water Efficient Plan. This is the supply addition that's represented by the Thornton Water Project Application they submitted to add some 20,000-acre feet in 2025. Well, lo and behold, what is this? This is another similar equivalent water supply addition. What's the date for that? 2034.

They're applying for their 1041 permit for

this seven years in advance. If they do the same for this, they're going to be back in 2027.

So this is important. This is your standard of review. This is how you need to look at this application from a legal standpoint. "If the proposed activity does not comply with the guidelines and regulations, the permit shall be denied." This is straight out of state law.

Your own Land Use Code has similar language. "When a 1041 Application may be approved only when the Applicant has satisfactorily demonstrated that the proposal, including all mitigation measures proposed by the Applicant, complies with all applicable criteria set forth in Section 14. If the proposal does not comply, the permit shall be denied."

The word "shall" is mandatory under your Land Use Code. So what is Thornton's burden of proof? They have the burden, not citizens, no one else. They have the burden. And they must prove that they've satisfactorily demonstrated. We believe that that term means a clear and convincing evidentiary burden of proof, not simply a bare preponderance of the evidence.

So what is your land use criteria say in Section 14 of the Land Use Code? It says that the Applicant must submit a complete and sufficient

Application. Well, this is basically incomplete just on Thornton's own cover letter of January 5th, 2018, where it says, "The source water pump station is not part of the permit application." It's not complete, deny it.

The 1041 Application must be denied because it fails to present all information on the source water pump that will be constructed as part of the TWP.

So now let's look at the very first criteria, substantive criteria in your Land Use Code. It says that the proposal must be consistent with the Master Plan. What does the Master Plan say about exporting water out of the county? It says, "Larimer County will not support" -- in other words, will not recommend in your situation -- "future transfers of existing water resources out of the county without consideration of the impacts on present and future land uses."

This Commission may not support or recommend in this case Thornton's application unless it provides information on all impacts on future land uses associated with the future Thornton Northern Project. Thornton's application fails to provide any information on future impacts associated with the remaining elements of the TNP. The Commission must recommend denial.

There is -- they got a better alternative, and that better alternative we refer to as the "Citizen's Poudre Alternative." And that is to withdraw water further downstream on the Poudre and let the Poudre be the pipeline.

What are the benefits to the county? It preserves the Poudre. You hear Thornton say, "Well, we're not going to take any more water out of the Poudre that's not already being taken." That's with this pipeline. They have a second pipeline that would have to draw additional water, so you're looking at reduced flows. You're also looking at the NIS (phonetic) pipeline staring this county down the neck, and you're going to have people running for your water and depleting the water supply in the Poudre.

So this pipe, this would help keep water in the Poudre further downstream. It would shorten the length of the pipeline. It would provide water through Old Town, and it will be fewer impacts to your residents.

The harm to Thornton? None.

Thornton's citizens -- the alternative is cheaper. It involves less infrastructure. It's feasible, and it has greater community acceptance.

This is a PowerPoint slide from one of

Thornton's own presentations. The concept one here is what is included in their application. You'll see the costs there are 400 to 500 million. The concept two here is to leave water in the Poudre further and take it out in Weld County. You'll see it's $50 million cheaper.

You'll also see the probability of success is similar, but one thing they don't look at is community acceptance. If you look at community acceptance, the probability of success is going to go way over into the green.

The citizen Poudre alternative is also feasible. In our comments we submitted a technical report by Lisa Buchanan, who is the hydrologist, and she looked at Thornton's claim that you couldn't take water further downstream. I believe Commissioner Jensen had a question about this.

Can you take it further downstream if it's not listed as a water supply use? You can. There is a segment that's further east of downtown that's still a water supply segment that they could pull out of, and in addition, if they wanted to pull further east, all you have to do is go the Water Quality Control Commission and ask for a change of that classification. It's done all the time, it's not a huge deal.

MR. DOUGHERTY: You have two minutes.

MR. BARTH: She also finds that the water quality near the reclamation plant in Fort Collins is similar to what they would pull out of the reservoir. So downstream diversion is feasible.

So here are the conditions that if you -- we're asking for denial, but if you don't deny, here are two conditions we ask you to impose in the alternative.

If Thornton is not going to submit full information on the full aspects of the TNP, then you ought to say, "Well, all right, we'll grant your permit, but don't come back again. This was your application. You had your chance for a full TNP application to tell us all of the impacts. Since you failed to do that, this is the only pipeline, this is the only structure associated with this project that we're ever going to approve."

The second alternative is to tell Thornton that since they're promising that they won't need to do anything more until 2065, is to say, "Fine. Don't come back until 2066. We're not going to accept anymore 1041 Applications for any other aspect of this project until then."

Any questions?

MR. DOUGHERTY: All right. Planning Commissioners questions for Mr. Barth?

Thank you, Mr. Barth.

Go ahead, Commissioner Carraway.

MR. CARRAWAY: Yeah, I'd just like if you could clarify from a legal standpoint your understanding of the power that the County has in regard to this issue of mitigation? Just how -- you know, I want to just go back to the question I asked Mr. Lafferty, and he talked about this issue of a connection or nexus between the project itself and, you know, any mitigation that's being asked for.

What's your understanding of that?

MR. BARTH: I agree with both of you. I agree that there needs to be some nexus. You can't pull something out of this sky and say, you know, we want you to pay us $10 million, with no relationship to the project.

But the questions you were asking were excellent. And they were mitigation questions, and you are fully entitled as a Planning Commission and as a County to require mitigation, including mitigation to the Poudre. So your questions were right on. You absolutely have a ton of discretion, as long as it's connected to the project, and down the road you're

going to get deference from the courts if you do the right thing.

If you, you know, completely ignore the law or you impose a requirement that's completely arbitrary, you're not going to get deference on that. But if you, you know, tailor your mitigation as we have proposed with our proposed amendments or conditions to say, "You're not coming back, because you've essentially violated 1041. You came in for a piece of this. Or you've asserted that you're not going to need any more water until 2065, don't come back until then."

Those are directly related. They're directly related to promises that they've made to you, and so you have a ton of discretion on mitigation and conditions.

MR. DOUGHERTY: Other questions for Mr. Barth?

Commissioner Jensen.

MR. JENSEN: What I didn't see you address, Mr. Barth, was the storage aspect for the City of Thornton. I think in their presentation they spoke very clearly that those reservoirs are an integral part of this process because of we all know what happens in the late summertime on the Poudre River and what happens in the early spring on the Poudre River. I

would think that storage would be a critical part of that, and I did not hear you address that in your alternative.

Can you speak to that, please?

MR. BARTH: Sure. So I am not an expert on their water system, and I'm not an expert in water law, Colorado water law, but what I can tell you is from reading the Water Court decisions, they have numerous reservoirs for storage. They have a significant percentage of the WSSC water rights. They have storage capability in the WSSC 4, they have other reservoirs further downstream. They also have rights to the various canals.

So what we would like to see, is we would like to see that explored. Give us a map, show us all your storage rights, show us the connections between the canals, and let's roll up our sleeves and work out an alternative that realy mitigates, helps the Poudre, and is acceptable to the community. Thus far, we have not had that approach with Thornton.

So I believe, given the amount of storage rights that they have and the variety of storage rights and the canal access, that this could be done.

MR. JENSEN: Thank you.

MR. DOUGHERTY: Commissioner Gerard?

MR. GERARD: Yes, sir. Have you looked at how many acres are going to be dried up with this water decree?

MR. BARTH: So that is a great point, and if you go back to that Master Plan requirement, that's exactly what it's pointing to. It says if you're taking water out of our county, you need to look at the impacts on agriculture. That's not in their application anywhere. And they've already dried up that land. They've dried up a bunch of it in order to be able to divert this water.

Where is that analysis? Mr. Koleber stood up and said, you know, well, we're doing the right thing. And we're, you know, make sure we don't get weeds and dust and stuff. Where's the analysis? This needs to be in this permit application.

So it's just a screaming deficiency with the application.

And I'd also like to just kind of respond to you and to Mr. Jensen --

MR. GERARD: Can you answer my question, though? Do you know how many acres?

MR. BARTH: I don't know exactly how many acres. I think the number of acres may be referred to in the application, I just can't remember what it is.

MR. GERARD: Okay. Thank you.

MR. BARTH: But there was an important aspect about the timing of the water use. Remember, their historic water use that was agricultural was only used a couple of months out of the year. High flows, you use it to irrigate crops. They've changed that.

Now they're using water year-round and storing that water year-round. So you've completely changed the hydrologic dynamics in the Poudre River by this change, and I'm not telling you that you can then question that because the Water Court has approved that change.

But we need to all know what the impacts of that are, and how it's going to change the Poudre, how is it going to change the ecology, how it's going to change the properties that have been dried up. And again, it's not in the application.

MR. DOUGHERTY: Thank you, Mr. Barth.

Any other questions for Mr. Barth?

(No audible response.)

MR. DOUGHERTY: Thank you very much, sir.

MR. BARTH: Thank you.

MR. DOUGHERTY: All right. Now we have, Roberta Norman is going to be up first, then we're going to have Patty Clifford and Mark Hyden (phonetic).

And we've actually got them up on the screen.

I would ask for Roberta to come on up and speak, please, and then Patty and Mark to please come sit on the chairs up in front here, so we can be as efficient as possible with timing.

And Roberta will have three minutes, as time was deferred to her.

Come on up, please.

MS. NORMAN: Yes, hi. My name is Roberta Norman. And I say where I live?

MR. DOUGHERTY: We don't need that. Thank you.

MS. NORMAN: No, not necessary, okay.

I'm very disappointed in what I've heard so far from the Planning Commission because I see you as thinking yourselves as victims and you're not, and we're here to empower you to do what the citizens are asking.

In the Land Use Code under Purpose of the Code, 2.3.1, and I quote -- this is taking it out of that, is: "To preserve, protect, and improve the health, safety and general welfare of Larimer County residents."

This is about Larimer County. It's not about Thornton. It is -- to say that the State has --

the Water Courts have said that the point of diversion is Reservoir 4 and cannot be changed, you know that's not true. We know that's not true. And will it take Thornton a little more time to get it changed? Yes, but is it going to take less time than building 20-plus -- a pipeline of 20-plus miles that's not needed? Their pipeline, as you know, passes the Poudre right down there by Windsor. They can start their pipeline diversion there.

It's going to take less time to get the Water Courts to change that diversion source and everything, but not as much time as it's going to take to build a pipeline 20-plus miles to get there, and it certainly is not going to interrupt as many people's lives.

And since the Commissioners are charged with preserving, protecting and improving the health, safety, and general welfare of Larimer County residents," allowing 26 miles of disturbance and impact to roads and private property when it's not necessary is not in the best interest of Larimer County residents.

The pipeline application aptly supports because it shows that pipeline crossing the Poudre. It can come out there.

And the $100 million that it takes for that

20-plus miles to go from Reservoir 4 down to the Poudre River down at Windsor, they could use that for building a wonderful reservoir for their residents in Thornton.

And I think that the Larimer County Commissioners should not consider and not be involved with Thornton's concerns. Those concerns being water quality, Government permits, time restraints, having to create reservoirs and having land already purchased in Larimer County. That has nothing to do with the 1041 and it has -- it has nothing to do with what the Commissioners should be doing.

They, again, should be --

MR. DOUGHERTY: Thank you. Thank you, Ms. Norman.

MS. NORMAN: Is it up? Okay. Thank you.

MR. DOUGHERTY: Appreciate that. Thank you.

Patty Clifford, you're up and Scott Horack (phonetic), you will be on deck after Mark Hyden.

MS. CLIFFORD: Hi. I'm Patty Clifford and we live in Wooded Creek. We've been there about 22 years in the house we're in right now.

When we were in Boulder, we built homes and Boulder had a moratorium on building more homes, and I think that Thornton should put a moratorium on this 50,000 people they're bringing in. And you know, those

50,000 homes that they're building in Thornton, they will all have two cars.

Do we want 100,000 more cars on I-25? So you know, I just think it's kind of crazy.

Anyway, that's all I have to say.

MR. DOUGHERTY: Thank you, Ms. Clifford.

All right. Mr. Mark Hyden, you're up and I'd ask Elaine Spencer to make her way on down for after Scott Horack.

MR. HYDEN: Well, it's clear this is a pretty complicated process here and I'm no lawyer, and I'm not -- I don't have a crystal ball. I don't know where this is headed in the future in 20 years or 40 years, and I'm not sure anybody in this room does.

And I'm here to address the 1041 Application as it's currently in front of the Commissioners, and the process that has taken place with that in regards to our perspective, meaning Eagle Lake.

I'm the president of the homeowners association at Eagle Lake and to us, the whole pipeline issue revolves around two specific points. One, public versus private property and the process that has taken so far to reach a decision in front of the Commission.

We fought hard and were supported by surrounding HOAs when the original Thornton corridor

was revealed to us about November of '16 when we saw it was coming straight out of Reservoir 4 going through Eagle Lake, then through private land off of Douglas Road, and it continued up through Woody Creek across Highway 1 into more private land on the other side of Highway 1.

We all wanted a solution that took advantage of public right-of-ways. Existing Thornton land and we wanted the pipeline to stay out of people's private property and backyards.

Both the County and Thornton listened to our suggestions and objections. They County allowed Thornton to use, as has been referenced, public right-of-ways and Thornton studied new routing for the pipeline that did exactly what came out of the meetings that we held with them, and that is utilization of traditional utility right-of-ways. Thornton owned land while not crossing private property, better known as the "Douglas Road option."

The anti-Douglas Road group protested this route over fears much like our own. That private land would be taken in the process, especially with the proposed widening of Douglas Road. But the process worked.

Through public meetings, private meetings

between Thornton and residents along Douglas Road, plus interaction with the County and the Transportation Department over the widening of the road, both the County and Thornton have listened and reacted to residents' concerns, much like they did with the original routing proposal through Eagle Lake.

The 1041 permitting process was delayed so Thornton could research utility locates under Douglas Road that did not require the taking of anyone's private property, and that process clearly demonstrated the pipeline could fit under the existing roadway.

There's not going to be a single house, tree, or fence lost in the pipeline route, if it goes completely under Douglas Road, as the residents there had feared and been told would happen.

The process also worked when Larimer County listened and reworked the road plan that Mr. Peterson showed us tonight with the improvement of Douglas Road that rightly reduced the width and the intrusion of the road into people's existing yards.

Contrary to what the propaganda has been, Thornton and Larimer County have been accommodating to all residents in the process. They've made changes based on resident input. They've protected private property rights with both the pipeline construction and

the reworking of Douglas Road.

In the eight months since the Douglas Road route was proposed, people have had their say and positive changes and results for all parties have occurred along the Douglas Road corridor.

No one has the right to call foul at this point over construction inconvenience when concerns have been met, especially on a public right-of-way. We are all impacted by it, but the sanctity of people's private land has been preserved in this process.

Thank you for listening and for addressing the County and Thornton people's concerns about the land and the private versus public aspect of it. The only thing left in our mind is for you to propose the route to the County Commissioners as a sensible solution for all parties.

MR. DOUGHERTY: Thank you, Mr. Hyden.

MR. HYDEN: Thank you.

MR. DOUGHERTY: Mr. Horack, Scott Horack is up. Then we have Elaine Spencer and Dick Brouch (phonetic).

MR. HORACK: Thank you, Commission.

My name is Scott Horack. I'd like to speak to a couple of issues here that weren't addressed in the 1040 and one of them would be eminent domain, and

the impacts.

Well, I'm not a fancy attorney like the City of Thornton. Back in the '80s when they designed this, you know, and it was designed, you know, from the beginning and it's pretty slick how they got this through. They changed the agricultural water rights to domestic water rights, which override everything else, but what I'm concerned about is that -- and all I know about the project is that water runs downhill. And below Reservoir No. 4, there is four reservoirs that haven't been addressed. There's Lyndon Meyer Lake, there is Long's Pond, there is Richard's Lake and there's Terry Lake.

Now what's going to happen to the water flows in those now that they're all the time, that water is going to be going out through pipelines right there, where all the people that own lake front property and enjoy that property are going to be looking at basically dry land wheat.

And that will save a little bit of problem for the Planning Commission here because you can just build your road right through the lakes that were there before, now they're just storage supply. So you won't have to worry about that, you know?

And I'm being sarcastic because a lot of

things that have been said today are sarcastic, like the good faith effort by Thornton is not a good faith effort. This has been planned since the 1980s. It is very strategic. It is very deceptive, and you shouldn't approve this permit based on what Thornton says because their word is obviously no good.

But yeah, the water levels in those lakes have not been addressed. The impacts to wildlife and the surrounding areas, and in our Constitution it says, "No person shall be deprived of life, liberty or property without due process of law." And this 1040 Application is a due process of law. And it's more on an administrative level with discretionary authority, but when discretionary authority becomes discriminatory authority, and used to -- and abuse.

There was a comment here that says, well, when Thornton asked for this application, that's what they get. Well, Thornton hasn't asked for anything. They've demanded and they've bullied everybody and they've just bullied their way right through this, so.

MR. DOUGHERTY: Thank you, Mr. Horack.

MR. HORACK: Okay. Thank you.

Did you have any question?

MR. DOUGHERTY: Any questions?

(No audible response.)

MR. DOUGHERTY: Thank you.

Elaine Spencer, you're up, then Dick Brouch and then Scarlet Sparkle Delia, and I know I messed that one up.

MS. SPENCER: It's Dick Brow.

MR. DOUGHERTY: Oh, okay. Thank you.

MS. SPENCER: My name is Elaine Spencer. I live at 3605 Bayshore Road, which t-bones into Douglas Road and it's just opposite where Dick Brow has his property and where the pump station will be located.

We've lived there for 30 years and this statement expresses the unanimous opinion of our Terry Acres Homeowners Association.

We are opposed to the pipeline being placed on Douglas Road corridor for the following reasons: The City of Thornton owns land north of Douglas Road. For some unknown reasons, it has been decided early on in the planning process, without any input from people who will be affected by the construction and declining property values, that Douglas Road is the preferred pipeline for their pipe -- route for their pipeline. It isn't.

This is a massive undertaking projected to take three to five years. There are 300 people who will be directly affected, many of whom live in older

subdivisions with single entrances.

It could be a nightmare in case of an emergency, not to mention the day-by-day delays, noise disruptions and inconveniences.

While the main purpose of this hearing is not the pump station. You need to think about Thornton's input into that, which will be directly opposite where our subdivision is. As night follows day, if the Douglas Road pipeline is approved, the rationale of the pump station is finalized, the constant noise, the pumping vibrations and the truck traffic will degrade our lifestyle and property values.

We urge you to deny Thornton's pipeline request. Yes, Thornton has a right to the water which they have bought, but they do not have the right to degrade our lives, our property values, and our safety, especially when we are most definitely not consulted about this and we had absolutely no input into such a life-changing event and such a financial blow to our property values. I doubt that any of you would like to life with what Thornton is proposing to have us live with.

Thank you.

MR. DOUGHERTY: Thank you very much, Ms. Spencer.

Mr. Brow, you are up. Scarlet Sparkle Delia is on deck, and then Dennis Pierrero.

MR. BROW: My concern is the Douglas Road pipeline installation. I don't know that you guys have fully explored the safety, the fact that roads are going to have to be closed on that road, and I think your number of trips per day is old. I think if you do it currently, you'll find it's a lot more than what was up on the board.

The other thing I want to say is taking a -- granting an easement to someone to put a pipeline in is not the same as them taking your property. They're not taking private property.

I don't feel like the northern route has been given fair -- you know, looked it over good enough compared to the traffic hazards and safety that's going to come up with this thing in the road at Douglas Road.

I've heard remarks about temporary four-hour closures of Douglas Road. I don't want to be the dead guy laying out in the field that called in and had a heart attack and had to wait four hours for the First Responders to get there.

So I think you need to go back, recommend to not okay the Douglas Road one. Go back and revisit both of those. Look at the costs. Look at the private

property taking, which won't exist on the northern route.

MR. DOUGHERTY: Thank you, Mr. Brow.

MR. BROW: And go from there.

MR. DOUGHERTY: Thank you very much, sir.

All right. We have Scarlet Sparkle Delia. Would you pronounce that for me? I know I messed it up.

MS. SPARKLE DELIA: You get an A-plus.

MR. DOUGHERTY: Cool. All right. That's rare.

Thank you. You have 10-1/2 minutes if my mic can work.

MS. SPARKLE DELIA: Do I go?

MR. DOUGHERTY: Yes. Feel free.

MS. SPARKLE DELIA: Oh, okay. All right.

Well you know my name. I am a member of the Braidwood Homeowners Association. I live approximately 900 feet from the proposed 10,000 square foot pump station. My family and I moved to the neighborhood 22 months ago from Southern California. I became aware of the Thornton Water Project at our annual HOA meeting in March of 2017.

The volunteer members from our HOA that followed the Thornton Water Project developments

reported that at that meeting, they had proposed a pump station the size of approximately 1500 square feet to sit at the south end of Reservoir No. 4.

And that's not their fault. Not only was this a gross inaccurate description of the pump station, it has purposefully misled many of the area residents about the size and scope of this project in its entirety.

Thornton has illegally segmented the pump station from the 1041 Application. For example, Thornton's January 5th, 2018 cover letter to its application, states: "As discussed with Larimer County Planning staff at the pre-application conference held on May 26, 2016, the source water pump station is not part of this 1041 Permit Application, but will be separately permitted through the site plan review permit process. Information on the source water pump station provided in the application is of a general nature and is included to present a more complete scope of the Thornton Water Project. To-date, not even a preliminary design or specification has been completed for the source water pump station and Thornton will submit a site plan review application to Larimer County in accordance with the LUC Section 6."

The pump station is appurtenant to the water

pipelines. The pump station is connected to the pipeline and will include 40 million gallons per day of pumps, a three-acre building site, a 10,000 square foot building, associated equipment, and emergency back-up diesel generator, industrial fencing, power lines, and security lighting. As such, the pump station has the potential to cause adverse impacts during construction and operation, including noise, air pollution, light pollution, storm water discharges, and degraded quality of life for adjacent residents.

Thornton's failure to include the source water pump station, which is aperturent to the pipeline in its 1041 Application renders the application incomplete and its attempt to have the pump station separately permitted through the site plan review process, rather than through the 1041 process constitutes an improper segmentation of the project, which prevents consideration of all collective impacts from the proposed project during the 1041 process.

The pump station is not an approved use in a farming zoning area. The 40 million gallon per day pump station is proposed on a parcel currently zoned "farming." Under Larimer County zoning regulations, the farming zoning does not allow a large water pumping station as an authorized use. Therefore, the pump

station may not be constructed or operated on the parcel in question without a change in zoning. Any change in zoning of that individual parcel would constitute illegal spot zoning.

In addition, any change to the zoning of the propsed pump station parcel would not be consistent with Larimer County Master Plan which states in LU-4, "In rural areas, allowed uses and residential densities shall be based on the current zoning of the property."

And LU-4-S2, "Changes an existing zoning shall be approved only when the change supports rural uses and maintains the open character of the rural area."

A change in zoning at the proposed pump station parcel would not support rural uses. Instead, it would allow an industrial high-capacity pumping operation in an otherwise rural farming area. The change in zoning would also destroy the open character of the rural area as would construction of the related pipeline.

Because the pump station parcel may not be rezoned from farming and Thornton's proposed use of the property does not comply with existing zoning, Thornton may not locate its pumping station at the proposed location.

Thornton does not want me or my neighbors to know the true scope of this facility until they get Larimer County approval for the first pipeline. When they come back to obtain approval by asking for illegal spot zoning to be changed from farming to industrial use, only then will they provide specifics on the pumps, potential generators, noise levels, light levels, and after that, maybe expand the size of the pump station to accommodate additional pipelines.

The potential impacts to my neighborhood include, but are not limited to noise pollution, light pollution, increased emissions, degradation of the rural landscape and degradation of our property values. These are quality of life issues.

Air pollution, what are the emissions from the pump operation? This isn't known because it's not included in the application, but I can speak to the admissions of nitrogen oxides and particulates; namely, nitric oxide and nitrogen dioxide from diesel engines that contribute to formation of smog and ozone and the worsening of respiratory diseases such as asthma, COPD or emphysema, bronchitis and aggravation of existing heart disease.

Noise pollution, what will this be? This isn't known because it's not included in the

application.

The National Fire Protection Association, 110 Section 8.4.2 references testing of emergency power supply systems. Specifically, diesel generators at a minimum of every month for 30 minutes. This testing length and frequency can vary the longer or more frequent based on the manufacturers recommendations.

And 2.6 technical committee on sound and vibration references sound produced by diesel generators, measured by sound pressure level, or DVA for reference. DVA of a quiet residential neighborhood is 45 DVA during daytime hours. 35 DVA at night. 100 feet from a busy freeway is 70 DVA. An orchestra is 92 DVA.

For a 125 kilowatt diesel generator, sound is measured at 86 DVA. In the case of the Thornton Water Project, one pump is 850 horsepower, which is equivalent to 633 kilowatts.

What type of a generator or generators wired in parallel are going to back up that level of power and be tested on at least a monthly basis -- and this is only one of the five pumps.

How could this even be proposed in a residential neighborhood? Property values? Home values in the pump ouse vicinity are anywhere from 3-

400 up to 2-plus million. Several hundred thousand dollar home value reductions due to this project is going to result in a signicant decrease in tax revenue to the County. Why would Larimer County elected officials approve such a budget cut? All of these potential impacts are to people like me. To the people in this room that live in the vicinity of this project, to our children who play on and around Starlight Drive, and in surrounding neighbors, to the families who start and end their days in this beautiful area of Larimer County.

The purposeful exclusion of the pump station from the Thornton Water Project 1041 Application has not gone unnoticed. It is perhaps the most pressing issue when evaluating the size and scale of this monumental long-term project guaranteed to adversely affect each and every one of this in ways yet unknown.

Thank you.

MR. DOUGHERTY: Thank you very much.

(Applause.)

MR. DOUGHERTY: Okay. Next we've got Dennis Pierrero, then Ryan Donovan is on deck and Ms. Karen Wagner will be third, but she's closer where she is, so she can stay sitting there if she'd like.

MR. PIERRERO: Thank you. Just a few

comments.

First is about maintaining our reservoirs. The dozens of small reservoirs in Noko are long-standing and well established water eco-systems that benefit our wildlife, including providing some very important habitats and they attract a great variety of birds, including many rareties.

The reservoirs also provide many opportunities for recreational activities. The reservoirs are clearly gems of our community; therefore, since Thornton will maintain their high quality water eco-systems in their current locations far into the future, I'm in support of this application. I would not like to see these go south.

Second, upholding private land rights. The use of public right-of-ways to harbor utility lines is a very common practice in the US and Douglas Road, my neighborhood road, currently has utility liens buried underneath it. It is how things get done.

The applicant intends to use public land where possible and for this reason, I support the application.

And lastly, process is in important. I'm instructed to follow and participate in the 1041 process, as I'm doing tonight, to guide my -- to guide

the impact on my property; therefore, I respectfully ask the County to do the same and rule on the merits of the application as is currently submitted. Taking into consideration topics and technicalities outside the scope of the project and process adds uncertainty, instability, and confusion to property owners current and future. This would not be helpful.

I ask that you please recommend approval of this application. Thank you.

MR. DOUGHERTY: Thank you, Mr. Pierrero.

Ryan Donovan is up, and then Karen Wagner is on deck and Karen Colobady is in the hole, if you will, third up.

MR. DONOVAN: Good evening, member of the Planning Commission and staff. My name is Ryan Donovan and my wife and I live at 3609 Bayshore Road, directly across Douglas Road from the pump station.

I practice in the area of water rights. I'm a water rights attorney, and I also teach water law and policy at Colorado State University.

There's been numerous gross misstatements of the law this evening on both sides, I think. Nevertheless, I felt compelled to talk after I heard the questions Mr. Carraway asked of Mr. Koleber about alternatives, particularly using the water -- or the

existing Larimer County Canal to transport the water.

I felt compelled to respond because I'm not sure that Mr. Koleber was completely accurate in his response. Certainly the pending or the current decree for Thornton's water rights limits their use and their place of use and their place of use and their points of diversion. But there is nothing under Colorado water law that would prevent Thornton from applying to store their senior water rights, which they already own, in new buckets. Those buckets can be located closer to Thornton. They can be located anywhere else, but they would significantly reduce the length of this pipeline.

I have numerous cases where my clients pending in Water Court now are doing just the same thing. I raise this as an issue because one of the Planning Commission's criteria for evaluating the plan is that the Applicant has provided a set of alternatives -- a complete set of alternatives. In this instance, I think Thornton has failed to do that. They have not examined this idea of using existing infrastructure and using existing water laws of our state to put that water in buckets, not put a pipeline 80-some miles from No. 4 down to Thornton.

And for that reason, I recommend that you recommend denying the application.

MR. DOUGHERTY: Thank you, Mr. Donovan.

Ms. Wagner, you are up, you've got 12 minutes. And thank you very much.

MS. WAGNER: Good evening. I don't know how I wound up with 12 minutes. I practiced and prepared for six.

MR. DOUGHERTY: Well, if you want to take less?

MS. WAGNER: But I'm going to talk real slowly, how's that?

(Laughter.)

MS. WAGNER: I am resident of Larimer County, of course. And I've lived in the Douglas Road area and until four years ago lived on Water Supply and Storage No. 4 in Eagle Lake in 16 years. So I'm well acquainted with the location and the geography of the area. But I also think besides the Douglas Road residents who have organized beyond belief, there are many residents throughout Larimer County along this whole 26 miles that have no idea of what's headed their way.

So first, since I have some extra minutes, I would like to thank the many, many people who spent untold hours and resources as everyday citizens trying to understand a very complicated application. And

unfortunately, it seems like that shouldn't be the job of a citizen. But it was. And so people like me spent a percentage of every day for the last six months trying to understand this project and envision a better alternative.

So, last fall some friends of mine asked for my advice regarding what was then called the Thornton Pipeline. They had heard about it from area residents who believed it was already a done deal. I agreed to help them negotiate a political system that was unfamiliar to them. I explained that the interest of citizens and of Larimer County in general are protected by the provisions of the Master Plan and the Land Use Code, both of which I worked on some 20 years ago with hundreds of other citizens.

I assured them that the member of the Planning Commission are every day citizens like them, who value the same quality of life and the natural environment that they do. To provide some peace of mind, I referred them to the stated purpose of the Land Use Code, which Ms. Clifford referred to earlier.

But I'd to repeat it because I love it. I think we did a good job on that. And it states that one of the purposes of the Code is to maintain and enhance property values by stabilizing expectations,

fostering predictability in land development, and establishing a process that efficiently applies the Code, while respect the property owner rights of Larimer County citizens.

That's what Larimer County is all about, property rights. We heard a lot about that when we worked on the Land Use Code.

Other stated purposes of the Code are to protect critical and environmental resources and promote the preservation of agriculture. You know that. I'm not telling you something that you don't know.

So I'm here tonight to ask you to consider the future impacts of the three pipeline, Thornton Northern Project, for residents all along the 26 miles of the proposed route.

And to make clear that should Larimer County approve Phase I, an additional 48-inch parallel pipeline and a 72-inch return flow pipeline, plus ditch exchanges, will be lining up for approval.

Thornton's own 2018 Water Efficiency Plan says that they'll need all their water in just 16 years. Mr. Koleber didn't say that tonight. They keep saying 2065, but do you really think they're going to wait till 2065? I don't.

If Larimer County approved Thornton's application for the Phase I Pipeline, you'll next be asked to consider illegal spot zoning of an agricultural property surrounded by residential for the industrial use of a pump station.

Is the Planning Commission prepared to consider an illegal spot zoning to jump start Thornton's pipeline? Really?

As citizen representatives of Larimer County, you have probably considered what the impacts would be if your home, your acreage, or farm should become pipeline central for years on end. And as someone mentioned earlier, we're not just talking about Thornton's three pipelines. We're talking about NISP (phonetic) and the County has worked with Northern Water and Thornton together on this pipeline corridor.

It's obviously to anyone with a passing familiarity with Thornton's plans that the project represents zero benefits to Larimer County and only hardships for County residents. Should construction start, residents are rightfully concerned that their property values will plummet and their quality of life will be severely diminished.

At minimum, the pipeline project will eliminate the beauty, privacy and sound proofing of

material landscaping. Residents may lose the enjoyment of their front or backyards and find a construction zone a few short yards from their doors.

When completed, the Thornton Northern Project will take homes and properties by eminent domain along its 26-mile course through Larimer County. The years of construction and road closures -- and we are talking years -- could affect residents' health and may force some to give up homes where they've lived and raised their families.

The 300-plus homes with single access from Douglas Road alone will experience unforgiving inconvenience for residents and home businesses, as well as delayed access for emergency responders.

Construction of the pipeline could easily eliminate units at two mobile home parks which represent part of Larimer County's small supply of affordable housing.

Residents near the intersection of Turnberry and Douglas will face the hazards associated with threading multiple pipelines through the 100-year old still active Prospect Energy Oilfield. What could possibly go wrong?

(Laughter.)

MS. WAGNER: On behalf of the citizens of

Larimer County, I ask you to deny Thornton's 1041 Application because it is incomplete, lacking in critical detail, and segments a massive project that will be detrimental to thousands of Larimer County residents for decades to come.

The Planning Commission is charged with protecting the property rights of Larimer County citizens, not facilitating the water rights of a Denver suburb that plans to use eminent domain.

Vote no tonight and ask Thornton to do the right thing, which is to avoid negatively impacting any Larimer County homes, properties, and neighborhoods, and to send its water through Fort Collins and the Poudre.

That which is an option that the City of Thornton has already determined will save their taxpayers 50 to $100 million. The less costly citizen's Poudre alternative can save a struggling river. They'll be making pipelines for a very long time, but they stop making rivers a long time ago.

Thank you for your consideration.

MR. DOUGHERTY: Thank you, Ms. Wagner.

Karen Colavity (phonetic) is up. Then we have Patricia Babbit, Harry Sheline (phonetic) and Penny Hillman.

MS. COLAVITY: Hello. My name is Karen Colavity. I'm actually a resident of Adams County and I know personally how Thornton operates.

Thornton, my dad and our family owned a property in an unincorporated Adams County for over 50 years. It just so happens that in the year of 2014, my dad died. Thornton had hoped to annex his -- asked to annex his property for years before that. I've noticed in some of the documents that Thornton has provided tonight that 2014 seemed to be a magic year for Thornton to see that it could take over a lot of things.

We hired a personal representative to represent our estate. Unfortunately that personal representative, who actually happens to be public administrator here in Larimer County, where they seem to be some connections, instead of treating our family fairly, started working hand-in-hand with Thornton.

Our property that had been in the family for 50 years and in 2008 had been appraised at $2.3 million, we knew that property values had gone down through the recession, but when we asked for a proper appraisal, so we would know how to take care of the estate, this person brought appraisers for 600,000 and it was sold to a church, the Mayor of Thornton presides

over.

MR. DOUGHERTY: Thank you, Ms. Colavity.

All right. Next we have Patricia Babbet (phonetic), then Harry Sheline (phonetic) and Penny Hillman.

MS. BABBET: I just want to say that a lot of my concerns have been addressed, especially by Elaine and Dick, Scarlett, Karen Wagner and Karen Colavity. I also am very aware of the situations where Thornton has been taking over a lot of property either through eminant domain or I would call "elder abuse."

And I'm just concerned of how things are working with this pipeline, as well. And one of the first things that was on a slide says that this project will cause no significant impacts to natural or man made environments, and I just don't see how that's possible with the pump station, 2.8-acre pump station, and this huge pipeline and I think we need to get a clear definition of what "significant" and "negative" and "mitigate" all mean because it's just not making any sense at all to me.

Thank you.

MR. DOUGHERTY: Thank you very much, Ms. Babbit.

Harry Sheline is up, then Penny Hillman, and

then Doug McAllister.

MR. SHELINE: I'm going to turn my time back in. My points have been made.

MR. DOUGHERTY: Thank you very much, Mr. Sheline.

Penny Hillman -- and I am going to ask please for Doug McAllister and Robert Kitchell to please come up front. That way we can go ahead and keep this moving along.

Thank you.

MS. HILLMAN: I've been writing new remarks, so I'm going to have to like shuffle through these, if you'll bear with me.

Repaired part of my remarks: There are so many critical unanswered questions and unresolved issues that should have been addressed long before this matter was brought before the Planning Commission. In March I wrote a letter, which hopefully is in your planning packet, to Thornton, Larimer County, Northern Water, recommending they hold a joint public hearing so the residents of Larimer County could have their questions and concerns openly answered and addressed before Thornton Amended 1041 was filed.

In my letter I requested the courtesy of a response. I heard nothing from Mr. Koleber, nothing

from Mr. Barnes of Thornton. I heard nothing from Northern Water. The only response I received was from Mr. Helmick saying, "We not intend to hold any further public meetings."

In January, Larimer County held a public information meeting for Douglas Road. Todd Bloomstrum faced some fierce fire at that meeting, but did a terrific job of listening to Larimer citizens and it appears facilitating supplements to Thornton's 1041 that directly addressed concerns voiced at that meeting.

Mark Peterson, in a letter dated March 14th, noted serious deficiencies in Thornton's submitted supplement of March 9 and sent it back for inclusion of additional information.

This is what it looks like when your County advocates for its citizens and I want to publicly thank them both for their work tonight.

As similarly formatted, public information meeting with Thornton and Larimer County had the potential to resolve contentious issues and facilitate the process of conflict resolution without the costly time intensive -- costly and time intensive lawsuits that are sure to result from voting prematurely on Thornton's 1041 permit.

I ask the Planning Commission to find Thornton's 1041 Application currently incomplete in order to allow time for Larimer County and Thornton to hold a series of joint public information meetings with the goal of reaching a mutually agreeable resolution with those who will be bearing the burden of Thornton's Pipe Dream, the citizens of Larimer County.

Now I'd like to address Mr. Koleber's remarks this evening wherein he stated the best overall score was Douglas Road because that is flat not true. By Thornton's own metrics as shown in Appendix A, Alternate Analysis of their 1041, it is not Douglas Road that received the best overall score, it is the North three route, which is County Road 56. I can forward that to you first thing in the morning if it's not easy for you to access.

Furthermore, the six component of Thornton's evaluation, which is entitled, "Coordinated Project Opportunities," was artificially inflated for Douglas Road, falsely multiplied by three, claiming that Thornton would lessen the impacts on the community by coordinating installation of their pipeline with the reconstruction of Douglas Road and the installation of the NIST (phonetic) pipeline.

If we are not going to deal in truth, what is

the point of any of this?

MR. DOUGHERTY: Thank you, Ms. Hillman.

MS. HILLMAN: Thank you.

MR. DOUGHERTY: Mr. McAllister and then Mr. Kitchell.

Yes. Go ahead, Commissioner Jensen.

MR. JENSEN: Ms. Hillman, we did get your letter, just so you want to know that it was part of our packet and we were provided an additional copy of that today also, just so that you know that we got that.

MS. HILLMAN: Appreciate it. Thank you very much.

MR. DOUGHERTY: All right. Mr. McAllister.

MR. MCALLISTER: Okay. In 2006 my wife and I bought some property on Woodridge Road and Douglas Road, right on the corner. The north side of the fence is along Douglas Road.

In 2006 we also opened Terry Lake Assisted Living where we take care of eight residents, average age between 85 and 98.

Now to say there isn't going to be an impact on this road, there is going to be an impact on this road and the impact is going to be on those elderly people because there's going to be dust and there's

going to be noise, and there's going to be a disruption of their quality of life because they can't go out like they did today on a beautiful day like this and sit outside with all the noise going on and everything else that's going to go right along, right outside the fence line.

Not only that, when this construction begins, it's possible that we may not even have any more opportunity for resident families to bring their parents there because of the situation that's going on.

So it will impact eight residents.

I don't know if I'm going to be able to keep it open. I don't know what impact it's going to have on that as far as getting people in and out. The nuisance it's going to be for the resident families and that kind of thing -- and I know it's only eight families, but I know also that there's a lot of people represented here that's lives are going to be affected that live in that area and it isn't going to affect everybody else in Larimer County and they probably don't care.

In 2006, I knew nothing about anything that's going to go on on Douglas Road and probably the people that built that house in 1969 didn't know either, and that was 30 years or so before Thornton even got water

rights for that.

So I really propose that they have an alternative route, the route that they planned on in the very beginning because they came in when this was already established and now they're just trying to ram that right through, which we really don't approve of, we don't want, and we hope that as a citizen of Larimer County and not Thornton, as representatives of the citizens of Larimer County, you will take that into consideration because we are the ones that are living in Larimer County, not the people in Thornton.

Thank you.

MR. DOUGHERTY: Thank you very much, Mr. McAllister.

Mr. Kitchell, you are up. After that we are going to take a quick break. I've been given a few notes that we need one, and it'll be a 10-minute break.

MR. KITCHELL: Good evening. I thought I had six minutes, but apparently three, so I'll have to compress things a bit here.

My name is Robert Kitchell, K-I-T-C-H-E-L-L. My wife and I live at 412 Terry Point Drive. We have done so for 25 years and our backyard backs up to Douglas Road. So we have a personal interest in the project.

As well, I'm a retired civil engineer and I have designed a number of pump stations and pipelines such as this over the years.

As addressed earlier, the Colorado Supreme Court in its 1996 decision describes the Thornton Northern Project as a three-phase project. Phase I is the Thornton Water Project, the subject of the 1041. Phase II includes a parallel 48-inch pipeline. And Phase III includes construction of a 72-inch return pipeline to convey flows to the Larimer County Canal.

This pipeline does not use Douglas Road corridor.

The alignment of the proposed pipeline is shown schematically in the recently submitted supplements as of early April. It's clear that Thornton has crafted it's current 1041 Application to only include Phase I of the Thornton Northern Project.

MR. DOUGHERTY: Mr. Kitchell, I hate to interrupt, but you do have six minutes, and I'm going to ask Mr. Lafferty to add three more. I just looked through here, so I want to make sure you have the time that you are supposed to have.

MR. KITCHELL: There is a God. Thank you.

(Laughter.)

MR. DOUGHERTY: Well, gotta be fair.

MR. KITCHELL: By way of background, the 1041 Permit Application, Section 2A2, general description TWP components in part included typically a 50-foot permanent easement for the water pipeline and an additional 40-foot temporary easement for construction will be purchased from property owners, except for the TWP will be constructed in road right-of-way.

The foregoing language describes a pipeline corridor which in concept and application is quite different from a typical utility occupied a road right-of-way. However, Thornton's recent supplements show the single 48-inch pipeline alignment within the 60-foot wide Douglas Road right-of-way, which does not meet the definition of a pipeline corridor.

It should be noted that approval of pipeline corridor would encourage the use by other utilities and projects, such as the Northern Integrated Supply Project. As indicated, the proposed pipeline alignment is schematic and the routing varies back and forth between the eastbound and westbound lanes. This in itself would not leave room for a second parallel pipeline, in my opinion.

In addition, there is an existing L-Co water district pipeline under Douglas Road that would have to be relocated. In the development services team

recommendations, Item 3 states that the pipeline alignment shown in the 1041 Application is considered conceptual in nature and demonstrates that the proposed lane can be located within the existing Douglas Road right-of-way west of County Road 11.

As you may imagine, I disagree with the assessment regarding use of the term "demonstrates."

Further, the supplements do not show cross-sections, typical or otherwise. Typical depth of burial of a water line or other wet utilities is five to seven feet. For this size pipeline, a trench depth of about 12 feet would be required. This would require trench shoring, bracing and blocking, given the limited room within the right-of-way for construction.

I'd like to contrast and compare other recommendations of the Development Services Team to the specific requirements of the Larimer County Rural Area Road Standards, that would have to be met during construction. The requirements of the standards are extensive, although some discretion is granted to the engineer.

Standards: Traffic flow during peak hours, no interference with traffic flow on arterial or collector roads such as Douglas Road shall be permitted between the hours of 7:00 a.m. and 8:30 a.m. or from

4:30 p.m. to 5:30 p.m., unless authorized in writing by the engineer.

Standards: End of day lane conditions, asphalt road. When work has stopped for the day, all lanes of an arterial or collector road shall be open to traffic unless approved by the engineer. A traffic lane shall be considered satisfactorily open only if it is paved with hot or cold mixed paving except when an alternative temporary service is allowed by the County as a condition of the permit.

Recommendations, Item 4, are somewhat softer than the County Road standards. In the interest of time, I won't go through them.

There's reference to the growth management area in Larimer County and for those who don't know, the Fort Collins CMA boundary is Douglas Road in our area.

Standards: Excavation. Trenches shall be excavated along the lines and grades established and in no case shall it be more than 200 feet in length or trenched and backfilled in non-continuous sections and so forth.

Again, the recommendation is contained in Item 12. Thornton shall construct the pipeline in phases, subject to phasing plans to be approved.

It is anticipated that work will only be allowed sequentially within one-mile segments for the alignment west of County Road 11.

Now in the interest of time, which is about up, it's quite clear that a second, parallel 48-inch pipeline would not be constructed within the Douglas Road right-of-way. This would necessitate a new routing.

In conclusion the deliberate approach of Thornton to not reveal the full extent of the Thornton Northern Project in its 1041 Permit Application would foreclose the option of a second parallel 48-inch pipeline as called for in Phase II, require a new pipeline corridor with a different routing when a second pipeline is needed.

And thank you for your time.

MR. DOUGHERTY: Thank you, Mr. Kitchell.

We are going to take a quick, ten-minute break, and we'll see you back here shortly.

(Recess taken.)

MR. DOUGHERTY: Now I'm going to ask for Janet Carabello, Georgia Locker, and Rick Steadman to please come on up.

MR. LAFFERTY: And Chairman Dougherty, Matt Lafferty real quick.

MR. DOUGHERTY: Yes, sir.

MR. LAFFERTY: Margaret Ho, Item No. 31, and Item 46, Belinda Koonce, both have decided not the speak, so you can strike those.

MR. DOUGHERTY: Excellent. Thank you very much.

All right. That tells me now that we are down to about 33 minutes of public comment left. So Janet Carabello, you are up. Janet is no longer here.

Okay. Then Georgia Locker, you are up. Then we have Rick Steadman, and then Sandy Hellsner.
